Developing Windows Applications **45**
Windows Overview 45

Procedures 47

CodeGuard Procedures **48**
Using CodeGuard 48

Database Procedures **50**
Accessing Schema Information 51
Using Data Explorer to Obtain Connection Information 52
Configuring TSQL Connection 53
Connecting to the Application Server using DataSnap Components 55
Debugging dbExpress Applications using TSQLMonitor 55
Executing the Commands using TSQLDataSet 56
Fetching the Data using TSQLDataSet 57
Specifying the Data to Display using TSQLDataSet 58
Specifying the Provider using TLocalConnection or TConnectionBroker 59
Using BDE 60
Using DataSnap 60
Using TBatchMove (BDE) 61
Connecting to Databases with TDatabase 62
Using TQuery (Procedure) 63
Using TSQLQuery 65
Using TSQLStoredProc (Procedure) 66
Using TSQLTable 66
Managing Database Sessions Using TSession 67
Using TSimpleDataSet 68
Using TSimpleObjectBroker 69
Using TStoredProc 69
Using TTable (Procedure) 70
Using TUpdateSQL to Update a Dataset 72
Using dbExpress 72
Adding a New Connection to the Data Explorer 73
Browsing a Database in the Data Explorer 74
Executing SQL in the Data Explorer 74
Modifying Connections in the Data Explorer 75
Connecting to a Database using the dbExpress Driver Framework 76

Interoperable Applications Procedures **79**

Using COM Wizards 79

Reporting Procedures 81

Adding Rave Reports to RAD Studio 81

VCL Procedures 82

Building a Windows "Hello World" Console Application 88
Developing a Windows Application 89
Building Application Menus 90
Building a VCL Forms Application with Decision Support Components 91
Building VCL Forms Applications With Graphics 93
Building a VCL Forms MDI Application Using a Wizard 93
Building a VCL Forms MDI Application Without Using a Wizard 94
Building a VCL Forms SDI Application 96
Creating a New VCL Component 97
Building a VCL Forms ADO Database Application 98
Building a VCL Forms Application 99
Creating Actions in a VCL Forms Application 100
Building a VCL Forms "Hello World" Application 101
Using ActionManager to Create Actions in a VCL Forms Application 102
Building a VCL Forms dbExpress Database Application 103
Building an Application with XML Components 104
Copying Data From One Stream To Another 106
Copying a Complete String List (VCL) 107
Creating Strings 109
Creating a VCL Form Instance Using a Local Variable 110
Deleting Strings 112
Displaying an Auto-Created VCL Form 113
Displaying a Bitmap Image in a VCL Forms Application 114
Displaying a Full View Bitmap Image in a VCL Forms Application 116
Drawing a Polygon in a VCL Forms Application 117
Drawing Rectangles and Ellipses in a VCL Forms Application 118
Drawing a Rounded Rectangle in a VCL Forms Application 118
Drawing Straight Lines In a VCL Forms Application 119
Dynamically Creating a VCL Modal Form 120
Dynamically Creating a VCL Modeless Form 121
Iterating Through Strings in a List 123
Building a Multithreaded Application 124
Writing Cleanup Code 125
Avoiding Simultaneous Thread Access to the Same Memory 125

Defining the Thread Object 126
Handling Exceptions 129
Initializing a Thread 130
Using the Main VCL Thread 131
Waiting for Threads 132
Writing the Thread Function (Procedure) 134
Placing A Bitmap Image in a Control in a VCL Forms Application 135
Reading a String and Writing It To a File 136
Renaming Files 137
Adding and Sorting Strings 138
Creating a VCL Forms ActiveX Button 139
Creating a VCL Forms ActiveX Active Form 140
Building a VCL Forms Web Browser Application 142
Creating an Application that Uses Ribbon Controls 143
Adding Commands to the Ribbon 144

WebSnap Procedures **147**
Building a WebSnap Application 148
Building a WebSnap "Hello World" Application 149
Debugging a WebSnap Application using the Web Application Debugger 150
Using the HTML Tag Editor 151

Web Services Procedure **153**
Building a "Hello World" Web Services Application 153

Reference 155

C++ Reference **156**
Command Line Utilities 156
BCC32, the C++ Command-Line Compiler 159
BRC32, the Resource Shell 163
BRCC32.EXE, the Resource Compiler 165
COFF2OMF.EXE, the Import Library Conversion Tool 166
CPP32.EXE, the C Compiler Preprocessor 167
DCC32.EXE, the Delphi Command Line Compiler 169
GREP.EXE, the text search utility 170
ILINK32.EXE, the Incremental Linker 174
IMPDEF.EXE, the Module Definition Manager 179
IMPLIB.EXE, the Import Library Tool 181
Using Include Files 182
MAKE 183

MAKE Directives 186
MAKE Macros 191
MAKE Rules (Explicit and Implicit) and Commands 193
Message Options 197
Module Definition Files 199
Using Precompiled Header Files 203
RLINK32.DLL, the Resource Linker (C++) 204
TDUMP.EXE, the File Dumping Utility 204
TLIB.EXE, the Library Manager 208
Using TOUCH.EXE 212
TRIGRAPH 213
RC.EXE, the Microsoft SDK Resource Compiler 213
WSDLIMP.EXE, the Command Line WSDL Import Tool 214
C++ Compiler Errors And Warnings (C++) 216
E2066: Invalid MOM inheritance (C++) 256
E2525: You must define _PCH_STATIC_CONST before including xstring to use this feature (C++) 257
E2526: Property 'name' uses another property as getter/setter; Not allowed (C++) 257
E2008: Published property access functions must use __fastcall calling convention (C++) 257
E2122: Function call terminated by unhandled exception 'value' at address 'addr' (C++) 257
E2506: Explicit specialization of 'specifier' is ambiguous: must specify template arguments (C++) 257
E2483: Array dimension 'specifier' could not be determined (C++) 258
E2509: Value out of range (C++) 258
E2510: Operand size mismatch (C++) 258
E2050: __declspec(delphireturn) class 'class' must have exactly one data member (C++) 258
E2530: Unrecognized option, or no help available (C++) 258
E2527: Option 'name' cannot be set via 'name' (C++) 258
E2528: Option 'name' must be set before compilation begins (C++) 258
E2074: Value after -g or -j should be between 0 and 255 inclusive (C++) 259
E2492: Properties may only be assigned using a simple statement, e.g. \"prop = value;\" (C++) 259
E2505: Explicit instantiation requires an elaborated type specifier (i.e.,"class foo<int>") (C++) 259
E2100: Invalid template declarator list (C++) 259
E2102: Cannot use template 'template' without specifying specialization parameters (C++) 260
E2107: Invalid use of template 'template' (C++) 260
E2105: 'template' qualifier must specify a member template name (C++) 260
E2066: Information not available (C++) 261
E2471: pragma checkoption failed: options are not as expected (C++) 261
E2504: 'dynamic' can only be used with non-template member functions (C++) 261
E2191: '__far16' may only be used with '__pascal' or '__cdecl' (C++) 261
E2199: Template friend function 'function' must be previously declared (C++) 262

E2502: Error resolving #import: problem (C++) 262
E2501: Unable to open import file 'filename' (C++) 262
E2494: Unrecognized __declspec modifier (C++) 262
E2493: Invalid GUID string (C++) 263
E2499: Invalid __declspec(uuid(GuidString)) format (C++) 263
E2496: Invalid call to uuidof(struct type|variable) (C++) 263
E2511: Unterminated macro argument (C++) 263
E2489: Maximum option context replay depth exceeded; check for recursion (C++) 263
E2488: Maximum token reply depth exceeded; check for recursion (C++) 263
E2491: Maximum VIRDEF count exceeded; check for recursion (C++) 263
E2230: In-line data member initialization requires an integral constant expression (C++) 264
E2241: VCL style classes need virtual destructors (C++) 264
E2524: Anonymous structs/unions not allowed to have anonymous members in C++ (C++) 264
E2246: x is not abstract public single inheritance class hierarchy with no data (C++) 264
E2249: = expected (C++) 264
E2267: First base must be VCL class (C++) 264
E2472: Cannot declare a member function via instantiation (C++) 265
E2515: Cannot explicitly specialize a member of a generic template class (C++) 265
E2474: 'function' cannot be declared as static or inline (C++) 265
E2498: Need previously defined struct GUID (C++) 266
E2295: Too many candidate template specializations from 'specifier' (C++) 266
E2475: 'function' cannot be a template function (C++) 266
E2299: Cannot generate template specialization from 'specifier' (C++) 267
E2300: Could not generate a specialization matching type for 'specifier' (C++) 267
E2497: No GUID associated with type:'type' (C++) 267
E2522: Non-const function 'function' called for const object (C++) 267
E2523: Non-volatile function 'name' called for volatile object (C++) 267
E2513: Cannot emit RTTI for 'parameter' in 'function' (C++) 267
E2512: Cannot emit RTTI for return type of 'function' (C++) 267
E2507: 'class' is not a direct base class of 'class' (C++) 268
E2529: Path 'path' exceeds maximum size of 'n' (C++) 268
E2495: Redefinition of uuid is not identical (C++) 268
E2500: __declspec(selectany) is only for initialized and externally visible variables (C++) 268
E2482: String constant expected (C++) 268
E2481: Unexpected string constant (C++) 268
E2386: Cannot involve parameter 'parameter' in a complex partial specialization expression (C++) 268
E2387: Partial specializations may not specialize dependent non-type parameters ('parameter') (C++) 269
E2388: Argument list of specialization cannot be identical to the parameter list of primary template (C++) 269
E2389: Mismatch in kind of substitution argument and template parameter 'parameter' (C++) 269

E2480: Cannot involve template parameters in complex partial specialization arguments (C++) 269
E2392: Template instance 'template' is already instantiated (C++) 270
E2393: Cannot take the address of non-type, non-reference template parameter 'parameter' (C++) 270
E2399: Cannot reference template argument 'arg' in template class 'class' this way (C++) 270
E2397: Template argument cannot have static or local linkage (C++) 270
E2485: Cannot use address of array element as non-type template argument (C++) 271
E2402: Illegal base class type: formal type 'type' resolves to 'type' (C++) 271
E2403: Dependent call specifier yields non-function 'name' (C++) 271
E2404: Dependent type qualifier 'qualifier' has no member type named 'name' (C++) 271
E2405: Dependent template reference 'identifier' yields non-template symbol (C++) 271
E2406: Dependent type qualifier 'qualifier' is not a class or struct type (C++) 272
E2407: Dependent type qualifier 'qualifier' has no member symbol named 'name' (C++) 272
E2408: Default values may be specified only in primary class template declarations (C++) 272
E2409: Cannot find a valid specialization for 'specifier' (C++) 272
E2410: Missing template parameters for friend template 'template' (C++) 273
E2486: Cannot use address of class member as non-type template argument (C++) 273
E2411: Declaration of member function default parameters after a specialization has already been expanded (C++) 273
E2412: Attempting to bind a member reference to a dependent type (C++) 273
E2414: Destructors cannot be declared as template functions (C++) 273
E2473: Invalid explicit specialization of 'specifier' (C++) 274
E2490: Specialization within template classes not yet implemented (C++) 274
E2416: Invalid template function declaration (C++) 274
E2417: Cannot specify template parameters in explicit specialization of 'specifier' (C++) 274
E2418: Maximum instantiation depth exceeded; check for recursion (C++) 274
E2420: Explicit instantiation can only be used at global scope (C++) 274
E2422: Argument kind mismatch in redeclaration of template parameter 'parameter' (C++) 275
E2423: Explicit specialization or instantiation of non-existing template 'template' (C++) 275
E2479: Cannot have both a template class and function named 'name' (C++) 275
E2484: The name of template class 'class' cannot be overloaded (C++) 275
E2426: Explicit specialization of 'specifier' requires 'template<>' declaration (C++) 275
E2487: Cannot specify default function arguments for explicit specializations (C++) 276
E2427: 'main' cannot be a template function (C++) 276
E2429: Not a valid partial specialization of 'specifier' (C++) 276
E2430: Number of template parameters does not match in redeclaration of 'specifier' (C++) 276
E2477: Too few template parameters were declared for template 'template' (C++) 276
E2478: Too many template parameters were declared for template 'template' (C++) 277
E2431: Non-type template parameters cannot be of floating point, class, or void type (C++) 277
E2434: Template declaration missing template parameters ('template<...>') (C++) 277

E2435: Too many template parameter sets were specified (C++) 277
E2436: Default type for template template argument 'arg' does not name a primary template class (C++) 277
E2437: 'typename' should be followed by a qualified, dependent type name (C++) 278
E2438: Template template arguments must name a class (C++) 278
E2439: 'typename' is only allowed in template declarations (C++) 278
E2440: Cannot generate specialization from 'specifier' because that type is not yet defined (C++) 278
E2441: Instantiating 'specifier' (C++) 278
E2503: Missing or incorrect version of TypeLibImport.dll (C++) 279
E2470: Need to include header <typeinfo> to use typeid (C++) 279
E2514: Cannot (yet) use member overload resolution during template instantiation (C++) 279
E2508: 'using' cannot refer to a template specialization (C++) 279
E2462: 'virtual' can only be used with non-template member functions (C++) 279
W8086: Incorrect use of #pragma alias "aliasName"="substituteName" (C++) 280
W8099: Static main is not treated as an entry point (C++) 280
W8093: Incorrect use of #pragma codeseg [seg_name] ["seg_class"] [group] (C++) 280
W8094: Incorrect use of #pragma comment(<type> [,"string"]) (C++) 280
W8085: Function 'function' redefined as non-inline (C++) 281
W8105: %s member '%s' in class without constructors (C++) 281
W8095: Incorrect use of #pragma message("string") (C++) 281
W8098: Multi-character character constant (C++) 281
W8096: Incorrect use of #pragma code_seg(["seg_name"[,"seg_class"]]) (C++) 281
W8083: Pragma pack pop with no matching pack push (C++) 282
W8097: Not all options can be restored at this time (C++) 282
W8084: Suggest parentheses to clarify precedence (C++) 282
W8092: 'type' argument 'specifier' passed to 'function' is not an iterator: 'type' iterator required (C++) 282
W8087: 'operator::operator==' must be publicly visible to be contained by a 'type' (C++) 283
W8090: 'type::operator<' must be publicly visible to be used with 'type' (C++) 283
W8089: 'type::operator<' must be publicly visible to be contained by a 'type' (C++) 283
W8091: 'type' argument 'specifier' passed to 'function' is a 'iterator category' iterator: 'iterator category' iterator required (C++) 283
W8076: Template instance 'specifier' is already instantiated (C++) 283
W8077: Explicitly specializing an explicitly specialized class member makes no sense (C++) 283
Informational messages (C++) 284
E2196: Cannot take address of member function 'function' (C++) 284
F1002: Unable to create output file 'filename' (C++) 284
F1003: Error directive: 'message' (C++) 284
F1004: Internal compiler error (C++) 284
F1006: Bad call of intrinsic function (C++) 284
F1007: Irreducible expression tree (C++) 285

F1009: Unable to open input file 'filename' (C++) 285
F1011: Register allocation failure (C++) 285
F1012: Compiler stack overflow (C++) 285
F1013: Error writing output file (C++) 285
F1000: Compiler table limit exceeded (C++) 285
F1005: Include files nested too deep (C++) 286
F1008: Out of memory (C++) 286
F1010: Unable to open 'filename' (C++) 286
E2000: 286/287 instructions not enabled (C++) 286
Abnormal program termination (C++) 286
E2009: Attempt to grant or reduce access to 'identifier' (C++) 286
E2011: Illegal to take address of bit field (C++) 286
E2010: Cannot add or subtract relocatable symbols (C++) 287
E2013: 'function1' cannot be distinguished from 'function2' (C++) 287
E2014: Member is ambiguous: 'member1' and 'member2' (C++) 287
E2015: Ambiguity between 'function1' and 'function2' (C++) 287
E2017: Ambiguous member name 'name' (C++) 287
E2019: 'identifier' cannot be declared in an anonymous union (C++) 288
E2020: Global anonymous union not static (C++) 288
E2022: Array size too large (C++) 288
E2024: Cannot modify a const object (C++) 288
E2025: Assignment to 'this' not allowed, use X::operator new instead (C++) 288
E2026: Assembler statement too long (C++) 288
E2001: Constructors and destructors not allowed in __automated section (C++) 289
E2002: Only __fastcall functions allowed in __automated section (C++) 289
E2003: Data member definition not allowed in __automated section (C++) 289
E2004: Only read or write clause allowed in property declaration in __automated section (C++) 289
E2005: Redeclaration of property not allowed in __automated section (C++) 290
E2027: Must take address of a memory location (C++) 290
E2028: operator -> must return a pointer or a class (C++) 290
E2029: 'identifier' must be a previously defined class or struct (C++) 290
E2030: Misplaced break (C++) 290
E2031: Cannot cast from 'type1' to 'type2' (C++) 290
E2033: Misplaced continue (C++) 291
E2034: Cannot convert 'type1' to 'type2' (C++) 291
E2036: Conversion operator cannot have a return type specification (C++) 292
E2037: The constructor 'constructor' is not allowed (C++) 292
E2039: Misplaced decimal point (C++) 292
E2041: Incorrect use of default (C++) 292

E2042: Declare operator delete (void*) or (void*, size_t) (C++) 293
E2044: operator delete must return void (C++) 293
E2045: Destructor name must match the class name (C++) 293
E2048: Unknown preprocessor directive: 'identifier' (C++) 293
E2046: Bad file name format in include directive OR Bad file name format in line directive (C++) 294
E2051: Invalid use of dot (C++) 294
E2053: Misplaced elif directive (C++) 294
E2054: Misplaced else (C++) 294
E2055: Misplaced else directive (C++) 294
E2056: Misplaced endif directive (C++) 295
E2059: Unknown language, must be C or C++ (C++) 295
E2060: Illegal use of floating point (C++) 295
E2061: Friends must be functions or classes (C++) 295
E2062: Invalid indirection (C++) 295
E2063: Illegal initialization (C++) 296
E2064: Cannot initialize 'type1' with 'type2' (C++) 296
E2068: 'identifier' is not a non-static data member and can't be initialized here (C++) 296
E2069: Illegal use of member pointer (C++) 296
E2071: operator new must have an initial parameter of type size_t (C++) 297
E2072: Operator new[] must return an object of type void (C++) 297
E2075: Incorrect 'type' option: option (C++) 297
E2076: Overloadable operator expected (C++) 297
E2080: 'function' must be declared with one parameter (C++) 298
E2077: 'operator' must be declared with one or no parameters (C++) 298
E2079: 'function' must be declared with no parameters (C++) 298
E2078: 'operator' must be declared with one or two parameters (C++) 298
E2081: 'function' must be declared with two parameters (C++) 298
E2082: 'identifier' must be a member function or have a parameter of class type (C++) 298
E2083: Last parameter of 'operator' must have type 'int' (C++) 299
E2084: Parameter names are used only with a function body (C++) 299
E2085: Invalid pointer addition (C++) 299
E2086: Illegal pointer subtraction (C++) 299
E2087: Illegal use of pointer (C++) 299
E2088: Bad syntax for pure function definition (C++) 300
E2089: Identifier 'identifier' cannot have a type qualifier (C++) 300
E2090: Qualifier 'identifier' is not a class or namespace name (C++) 300
E2092: Storage class 'storage class' is not allowed here (C++) 300
E2096: Illegal structure operation (C++) 300
E2104: Invalid use of template keyword (C++) 300

E2108: Improper use of typedef 'identifier' (C++) 301
E2109: Not an allowed type (C++) 301
E2110: Incompatible type conversion (C++) 301
E2113: Virtual function 'function1' conflicts with base class 'base' (C++) 301
E2114: Multiple base classes require explicit class names (C++) 301
E2115: Bit field too large (C++) 301
E2116: Bit fields must contain at least one bit (C++) 301
W8005: Bit fields must be signed or unsigned int (C++) 302
E2119: User break (C++) 302
E2111: Type 'typename' may not be defined here (C++) 302
E2121: Function call missing) (C++) 302
E2123: Class 'class' may not contain pure functions (C++) 302
E2126: Case bypasses initialization of a local variable (C++) 302
E2127: Case statement missing : (C++) 302
E2128: Case outside of switch (C++) 302
E2129: Character constant too long (or empty) (C++) 303
E2133: Unable to execute command 'command' (C++) 303
E2134: Compound statement missing closing brace (C++) 303
E2137: Destructor for 'class' required in conditional expression (C++) 303
E2135: Constructor/Destructor cannot be declared 'const' or 'volatile' (C++) 303
E2138: Conflicting type modifiers (C++) 303
E2136: Constructor cannot have a return type specification (C++) 303
E2038: Cannot declare or define 'identifier' here: wrong namespace (C++) 304
E2154: Cannot define 'identifier' using a namespace alias (C++) 304
E2421: Cannot use local type 'identifier' as template argument (C++) 304
E2035: Conversions of class to itself or base class not allowed (C++) 304
E2139: Declaration missing ; (C++) 304
E2140: Declaration is not allowed here (C++) 304
E2141: Declaration syntax error (C++) 304
E2142: Base class 'class' contains dynamically dispatchable functions (C++) 304
E2143: Matching base class function 'function' has different dispatch number (C++) 305
E2144: Matching base class function 'function' is not dynamic (C++) 305
E2145: Functions 'function1' and 'function2' both use the same dispatch number (C++) 305
E2146: Need an identifier to declare (C++) 305
E2147: 'identifier' cannot start a parameter declaration (C++) 305
E2150: Type mismatch in default argument value (C++) 305
E2152: Default expression may not use local variables (C++) 306
E2153: Define directive needs an identifier (C++) 306
E2155: Too many default cases (C++) 306

E2156: Default outside of switch (C++) 306
E2158: Operand of 'delete' must be non-const pointer (C++) 306
E2159: Trying to derive a far class from the huge base 'base' (C++) 306
E2160: Trying to derive a far class from the near base 'base' (C++) 306

Name	Description
Debugging C++ Applications with CodeGuard Error Reporting (see page 3)	CodeGuard provides runtime debugging for C++ applications developed with RAD Studio. CodeGuard reports errors that are not caught by the compiler because they do not violate syntax rules. CodeGuard tracks runtime libraries with full support for multithreaded applications.
Developing Database Applications for the Win32 Platform (see page 13)	The Borland Database Engine (BDE) has been deprecated, so it will not be enhanced. For instance, BDE will never have Unicode support. You should not undertake new development with BDE. Consider migrating your existing database applications from BDE to dbExpress. Database applications let users interact with the information that is stored in the databases. Databases provide structure for the information, and allow it to be shared among different applications. Delphi provides support for relational database applications. Relational databases organize information into tables, which contain rows (records) and columns (fields). These tables can be manipulated by simple operations known as... more (see page 13)
Developing Interoperable Applications (see page 29)	RAD Studio provides wizards and classes to make it easy to implement applications based on the Component Object Model (COM) from Microsoft. With these wizards, you can create COM-based classes and components to use within applications or you can create fully functional COM clients or servers that implement COM objects, Automation servers (including Active Server Objects), ActiveX controls, or ActiveForms.
Developing Reports for Your Win32 Applications (see page 35)	RAD Studio ships with Rave Reports from Nevrona. Using the report components, you can build full-featured reports for your applications. You can create solutions that include reporting capabilities which can be used and customized by your customers. Additionally, the ComponentOne tools that ship with RAD Studio include components for creating and generating reports.
Developing Applications with VCL Components (see page 36)	The Visual Component Library (VCL) is a set of visual components for the rapid development of Windows applications in the Delphi language. VCL contains a wide variety of visual, non-visual, and utility classes for tasks such as building Windows applications, web applications, database applications, and console applications.
Developing Web Applications with WebSnap (see page 41)	This section provides a conceptual background for building WebSnap applications using RAD Studio. WebSnap makes it easier to build Web server applications that deliver complex, data-driven Web pages. WebSnap's support for multiple modules and for server-side scripting makes development and maintenance easier for teams of developers and Web designers. Please note that WebSnap is being deprecated in RAD Studio. Although WebSnap is still documented in the online help, the WebSnap product is no longer fully supported. As an alternative, you should begin using IntraWeb (VCL for the Web). IntraWeb (see page 2254) is documented in this online help. For more documentation on VCL... more (see page 41)

Developing Web Services with Win32 Applications (see page 44)	Web Services are self-contained modular applications that can be published and invoked over the Internet. Web Services provide well-defined interfaces that describe the services provided. Unlike Web server applications that generate Web pages for client browsers, Web Services are not designed for direct human interaction. Rather, they are accessed programmatically by client applications. This section gives an overview of web services and web services support.
Developing Windows Applications (see page 45)	Windows provides a traditional approach to developing user interfaces, client/server applications, controls, and application logic. This section provides an overview of Windows application development using RAD Studio for Win32 and outlines the steps you would use to build a simple Windows project.

1.1 Debugging C++ Applications with CodeGuard Error Reporting

CodeGuard provides runtime debugging for C++ applications developed with RAD Studio. CodeGuard reports errors that are not caught by the compiler because they do not violate syntax rules. CodeGuard tracks runtime libraries with full support for multithreaded applications.

Topics

Name	Description
CodeGuard Errors (see page 3)	CodeGuard reports four types of runtime errors.
CodeGuard Overview (see page 9)	CodeGuard provides runtime debugging for C++ applications developed with RAD Studio. CodeGuard reports errors that are not caught by the compiler because they do not violate syntax rules. CodeGuard tracks runtime libraries with full support for multithreaded applications. CodeGuard provides two principal types of coverage: • Memory and Resource Use • Function Call Validation
CodeGuard Warnings (see page 10)	CodeGuard can report situations where your application may access memory beyond a buffer's maximum size. Warnings are available for three types of runtime library functions.

1.1.1 CodeGuard Errors

CodeGuard reports four types of runtime errors.

Topics

Name	Description
Access Errors (see page 4)	Access errors result from improper memory management. When CodeGuard detects accesses to freed memory blocks or deleted objects, it can identify where each block was allocated and deleted. Enable the **Delay Free** option using the **CodeGuard Configuration** dialog box to use this feature. The following are types of access errors: • Access in freed memory • Access in uninitialized stack • Access in invalid stack
Exception Errors (see page 5)	When a system exception occurs, CodeGuard reports the runtime error using information provided by the operating system. If possible, the CodeGuard log shows where your application caused the exception. CodeGuard does not trap or redirect the exception or otherwise interfere with normal program behavior. The following exceptions illustrate how CodeGuard exception reporting: • General Protection Fault • Divide by zero
Function Failure Errors (see page 6)	CodeGuard reports function calls that fail, as indicated by their return value. In the following example, the `close` function is given an invalid file handle, which causes it to return a value indicating that it was unable to close a file.

Resource Errors (see page 7)	Resources are memory blocks (allocated with functions like `malloc`, `GlobalAlloc`) and object arrays, such as file handles, stream handles, modules, and items returned by **new[]**. The following runtime error examples illustrate how CodeGuard reports improper use of resources: • Bad parameter • Reference to freed resource • Resource type mismatch • Resource leaks • Resource from different RTL

1.1.1.1 Access Errors

Access errors result from improper memory management.

When CodeGuard detects accesses to freed memory blocks or deleted objects, it can identify where each block was allocated and deleted. Enable the **Delay Free** option using the **CodeGuard Configuration** dialog box to use this feature.

The following are types of access errors:

- Access in freed memory
- Access in uninitialized stack
- Access in invalid stack

Access In Freed Memory

In the following example, CodeGuard identifies the line where an invalid access occurrs. CodeGuard then indicates where the memory block was allocated and subsequently freed.

```
Error 00004. 0x100430 (Thread 0xFFF87283):
Access in freed memory: Attempt to access 19 byte(s) at 0x00B423DC.
strcpy(0x00B423DC, 0x004091CA ["Copy to free block"])
| lang.cpp line 106:
|
|    free(buf_h);
|>   strcpy(buf_h, "Copy to free block");
|
|    //----------------------//
Call Tree:
   0x004011F1(=LANG.EXE:0x01:0001F1) lang.cpp#106
   0x00407EE5(=LANG.EXE:0x01:006EE5)

The memory block (0x00B423DC) [size: 21 bytes] was allocated with malloc
| lang.cpp line 80:
|    char * pad = (char *) malloc(200);
|    // An array in the RTL heap.
|>   char * buf_h = (char *) malloc(21);
|    char * p;
|    // A scratch buffer.
Call Tree:
   0x004011A1(=LANG.EXE:0x01:0001A1) lang.cpp#80
   0x00407EE5(=LANG.EXE:0x01:006EE5)

The memory block (0x00B423DC) was freed with free
| lang.cpp line 105:
|    //-------------//
|
|>   free(buf_h);
|    strcpy(buf_h, "Copy to free block");
```

```
|
Call Tree:
   0x004011E5(=LANG.EXE:0x01:0001E5) lang.cpp#105
   0x00407EE5(=LANG.EXE:0x01:006EE5)
```

Access In Uninitialized Stack

In the following example, the pointer `p` became invalid when `getBadLocal` returned from execution. No additional information is provided because the stack frame for `getBadLocal` was automatically removed.

```
Error 00005. 0x120400 (Thread 0xFFF87283):
Access in uninitialized stack: Attempt to access 20 byte(s) at 0x0072FC88.
memcpy(0x0072FCC4, 0x0072FC88, 0x14 [20])
| lang.cpp line 112:
|    //----------------------//
|    p = getBadLocal();
|>   memcpy(buffer, p, 20);
|
|    //-------------//
Call Tree:
   0x00401208(=LANG.EXE:0x01:000208) lang.cpp#112
   0x00407EE5(=LANG.EXE:0x01:006EE5)
```

Access In Invalid Stack

In the following example, an allocation was made for `buf_s` on the stack. However, the `strcpy` function writes just below the beginning of the valid stack region. CodeGuard identifies this as an error even if the string is only one byte long.

```
Error 00002. 0x110400 (Thread 0xFFF87283):
Access in invalid stack: Attempt to access 22 byte(s) at 0x0072FD8F.
strcpy(0x0072FD8F, 0x00409188 ["This string is long!\n"])
| LANG.CPP line 93:
|
|    // Stack underrun:
|>   strcpy(buf_s -1, "This string is long!\n");
|
|    // Global data overrun:
Call Tree:
   0x004011C5(=LANG.EXE:0x01:0001C5) LANG.CPP#93
   0x00407EED(=LANG.EXE:0x01:006EED)
```

1.1.1.2 Exception Errors

When a system exception occurs, CodeGuard reports the runtime error using information provided by the operating system. If possible, the CodeGuard log shows where your application caused the exception. CodeGuard does not trap or redirect the exception or otherwise interfere with normal program behavior.

The following exceptions illustrate how CodeGuard exception reporting:

- General Protection Fault
- Divide by zero

General Protection Fault

In the following example, CodeGuard provides information on a general protection fault (Intel system exception `0xD`). In addition to the location of the source code that caused the exception, the log shows where the memory was allocated and subsequently freed. The reported incorrect value is a result of accessing a byte pattern that CodeGuard uses to identify invalid memory locations.

```
Error 00003. 0x400003 (Thread 0x0090):
Exception 0xC0000005: Access violation at 0x80828082.
| gpfault.c line 32:
|    {¬
|       q = p[3];
```

```
|>      *q = 1;
|    }
| }
Call Tree:
   0x004010E5(=GPFAULT.EXE:0x01:0000E5) gpfault.c#32
   0x00406B29(=GPFAULT.EXE:0x01:005B29)

The bogus value (0x80828082) was most likely retrieved by accessing a(n)
 memory block that has already been freed
The memory block (0x008322A4) [size: 16 bytes] was allocated with malloc
| gpfault.c line 17:
|     int *q;
|
|>   p = malloc(sizeof(*p) * 4);
|
|    /*  Initialize p */
Call Tree:
   0x00401094(=GPFAULT.EXE:0x01:000094) gpfault.c#17
   0x00406B29(=GPFAULT.EXE:0x01:005B29)

The memory block (0x008322A4) was freed with free
| gpfault.c line 17:
|     int *q;
|
|>   p = malloc(sizeof(*p) * 4);
|
|    /*  Initialize p */
Call Tree:
   0x00401094(=GPFAULT.EXE:0x01:000094) gpfault.c#17
   0x00406B29(=GPFAULT.EXE:0x01:005B29)
```

Divide By Zero

In the following example, CodeGuard identifies the location in source code where division by zero (Intel system exception `0x0`) occurred.

```
Error 00001. 0x400000 (Thread 0x008B):
Exception 0xC0000094:
| ZERODIV.C line 9:
| {¬
|  x = 1;
|> return x / y;
| }
|
Call Tree:
   0x0040109C(=ZERODIV.EXE:0x01:00009C) ZERODIV.C#9
   0x00406321(=ZERODIV.EXE:0x01:005321)
```

1.1.1.3 Function Failure Errors

CodeGuard reports function calls that fail, as indicated by their return value.

In the following example, the `close` function is given an invalid file handle, which causes it to return a value indicating that it was unable to close a file.

```
Error 00009. 0x820000 (r) (Thread 0xFFF840F1):
Function failure:
close(0x80868086 [-2138668922])=0xFFFFFFFF [-1]
| lang.cpp line 125:
|    // uninitialized data usage //
|    //--------------------------//
|>   close(m->handle);
|
|
Call Tree:
```

```
   0x00401236(=LANG.EXE:0x01:000236) lang.cpp#125
   0x00407EED(=LANG.EXE:0x01:006EED)
```

1.1.1.4 Resource Errors

Resources are memory blocks (allocated with functions like `malloc`, `GlobalAlloc`) and object arrays, such as file handles, stream handles, modules, and items returned by **new[]**.

The following runtime error examples illustrate how CodeGuard reports improper use of resources:

- Bad parameter
- Reference to freed resource
- Resource type mismatch
- Resource leaks
- Resource from different RTL

Bad Parameter

When a resource is passed to a function, CodeGuard checks the runtime arguments. CodeGuard notifies you if it detects a bad parameter.

```
Error 00017. 0x310000 (Thread 0xFFF87283):
Bad parameter: A bad file handle (0xEA) has been passed to the function.
close(0xEA [234])
| lang.cpp line 170:
|    // using a bad handle //
|    //--------------------//
|>   close(234);
|
|    //----------------------//
Call Tree:
   0x00401456(=LANG.EXE:0x01:000456) lang.cpp#170
   0x00407EE5(=LANG.EXE:0x01:006EE5)
```

Reference To Freed Resource

In the following example, CodeGuard reports an attempt to read from a file that has already been closed. The CodeGuard log shows where the file was opened and subsequently closed.

```
Error 00020. 0x310030 (Thread 0xFFF840F1):
Reference to freed resource:
read(0x3 [3], 0x0072FCC4, 0x5 [5])
| lang.cpp line 177:
|    int i = open("lang.cpp", 0);
|    close(i);
|>   read (i, buffer, 5);
|
|    //--------------//
Call Tree:
   0x00401487(=LANG.EXE:0x01:000487) lang.cpp#177
   0x00407EED(=LANG.EXE:0x01:006EED)

The file handle (0x00000003) [name: 'lang.cpp'] was opened with open
| lang.cpp line 175:
|    // using a freed handle //
|    //----------------------//
|>   int i = open("lang.cpp", 0);
|    close(i);
|    read (i, buffer, 5);
Call Tree:
   0x0040146C(=LANG.EXE:0x01:00046C) lang.cpp#175
   0x00407EED(=LANG.EXE:0x01:006EED)
```

```
The file handle (0x00000003) was closed with close
| lang.cpp line 176:
|    //----------------------//
|    int i = open("lang.cpp", 0);
|>   close(i);
|    read (i, buffer, 5);
|
Call Tree:
   0x00401477(=LANG.EXE:0x01:000477) lang.cpp#176
   0x00407EED(=LANG.EXE:0x01:006EED)
```

Resource Type Mismatch

In the following example, a memory block that was allocated with the **new[]** operator, and should therefore be released with the **delete[]** operator, is instead released with a call to the `free` function.

```
Error 00024. 0x350010 (Thread 0xFFF840F1):
Resource type mismatch: a(n) memory block was expected.
free(0x00B42464)
| lang.cpp line 188:
|    //---------------//
|    char * ss = new char[21];
|>   free(ss);
|
| #ifdef    __WIN32__
Call Tree:
   0x0040149F(=LANG.EXE:0x01:00049F) lang.cpp#188
   0x00407EED(=LANG.EXE:0x01:006EED)

The object array (0x00B42464) [size: 21 bytes] was created with new[]
| lang.cpp line 187:
|    // type mismatch //
|    //---------------//
|>   char * ss = new char[21];
|    free(ss);
|
Call Tree:
   0x00401498(=LANG.EXE:0x01:000498) lang.cpp#187
   0x00407EED(=LANG.EXE:0x01:006EED)
```

Resource Leaks

In the following example, memory has been allocated but is never freed.

```
The memory block (0x00B42310) [size: 200 bytes] was allocated with malloc
| lang.cpp line 78:
|    // An array on the stack.
|    char buf_s[21];
|>   char * pad = (char *) malloc(200);
|    // An array in the RTL heap.
|    char * buf_h = (char *) malloc(21);
Call Tree:

```

Resource From Different RTL

CodeGuard reports an error if your application allocates, uses, or releases resources in different versions of the runtime library. This can happen, as the following example illustrates, if you link with a static runtime library but call a DLL.

Note: CodeGuard detects resource type mismatches before it detects mixed versions of the RTL. When the two kinds of error are combined, CodeGuard will not report the mixed RTLs until you correct the resource type mismatch.

```
Error 00001. 0x340010 (Thread 0x0062):
Resource from different RTL:
```

```
close(0x3 [3])
| testdll.cpp line 23:

1.1.2 CodeGuard Overview

CodeGuard provides runtime debugging for C++ applications developed with RAD Studio. CodeGuard reports errors that are not caught by the compiler because they do not violate syntax rules. CodeGuard tracks runtime libraries with full support for multithreaded applications.

CodeGuard provides two principal types of coverage:

- Memory and Resource Use
- Function Call Validation

Memory and Resource Use

CodeGuard checks for faulty memory use, improper memory allocation or deallocation, invalid file streams or handles, and resource leaks caused by improper use of file streams or handles. CodeGuard verifies pointer dereferencing and pointer arithmetic. CodeGuard can report an error if your program tries to access memory or resources that have already been released.

Function Call Validation

CodeGuard verifies function arguments and reports function failure as indicated by the return value of the function. It validates Windows resource handles used in function calls.

CodeGuard Errors (see page 3)

CodeGuard Warnings (see page 10)

Using CodeGuard (see page 48)

1

1.1.3 CodeGuard Warnings

CodeGuard can report situations where your application may access memory beyond a buffer's maximum size. Warnings are available for three types of runtime library functions.

Topics

Name	Description
Memory Block Comparison Warnings (see page 11)	Each of the following functions has a parameter that determines the maximum number of bytes it compares: 1. `memcmp` 2. `memicmp` 3. `_fmemcmp` 4. `_fmemicmp` If the **Warnings** option is enabled for the functions listed above, CodeGuard verifies that a comparison can be performed for each memory block passed to the function. If a memory block is too large, as determined by the parameter passed to the function, CodeGuard generates a warning. If the **Warnings** option is disabled for the functions listed above, CodeGuard checks the first byte in each memory block passed to the function. If the memory block is invalid, CodeGuard generates... more (see page 11)
Pathname Merging and Splitting Warnings (see page 11)	Each of the following functions use constants defined in `dir.h` to determine the maximum number of bytes to copy to or from a buffer: 1. `fnmerge` 2. `fnsplit` 3. `getcurdir`
String Comparison Warnings (see page 11)	Each of the following functions has a parameter that determines the maximum number of bytes it compares: • `strncmp` • `strnicmp` • `strncmpi` • `_fstrncmp` • `_fstrnicmp` If the **Warnings** option is enabled for the functions listed, CodeGuard verifies that a string comparison can be performed for each buffer passed to the function. If the buffer size is too large, as determined by the parameter passed to the function, and the buffer is not null-terminated, CodeGuard generates a warning. If the **Warnings** option is disabled for the functions listed above, CodeGuard checks the first byte in each memory block passed to the function. If the... more (see page 11)

1.1.3.1 Memory Block Comparison Warnings

Each of the following functions has a parameter that determines the maximum number of bytes it compares:

1. `memcmp`
2. `memicmp`
3. `_fmemcmp`
4. `_fmemicmp`

If the **Warnings** option is enabled for the functions listed above, CodeGuard verifies that a comparison can be performed for each memory block passed to the function. If a memory block is too large, as determined by the parameter passed to the function, CodeGuard generates a warning.

If the **Warnings** option is disabled for the functions listed above, CodeGuard checks the first byte in each memory block passed to the function. If the memory block is invalid, CodeGuard generates an error message.

1.1.3.2 Pathname Merging and Splitting Warnings

Each of the following functions use constants defined in `dir.h` to determine the maximum number of bytes to copy to or from a buffer:

1. `fnmerge`
2. `fnsplit`
3. `getcurdir`

fnmerge

If the **Warnings** option is enabled, the output buffer is validated against `MAXPATH` before `fnmerge` is called.

If the **Warnings** option is disabled, the size of the output buffer is validated against the null-terminated string length after `fnmerge` is called.

fnsplit

If the **Warnings** option is enabled, the input buffers are validated against `MAXDRIVE`, `MAXDIR`, `MAXFILE`, and `MAXEXT` before `fnsplit` is called.

If the **Warnings** option is disabled, the input buffers are validated against the length of the null-terminated string after `fnsplit` is called.

getcurdir

If the **Warnings** option is enabled, the output buffer is validated against `MAXDIR` before `getcurdir` is called.

If the **Warnings** option is disabled, the output buffer is validated against the length of the null-terminated string after `getcurdir` is called.

1.1.3.3 String Comparison Warnings

Each of the following functions has a parameter that determines the maximum number of bytes it compares:

- `strncmp`
- `strnicmp`
- `strncmpi`

- `_fstrncmp`
- `_fstrnicmp`

If the **Warnings** option is enabled for the functions listed, CodeGuard verifies that a string comparison can be performed for each buffer passed to the function. If the buffer size is too large, as determined by the parameter passed to the function, and the buffer is not null-terminated, CodeGuard generates a warning.

If the **Warnings** option is disabled for the functions listed above, CodeGuard checks the first byte in each memory block passed to the function. If the memory block is invalid, CodeGuard generates an error message.

1.2 Developing Database Applications for the Win32 Platform

The Borland Database Engine (BDE) has been deprecated, so it will not be enhanced. For instance, BDE will never have Unicode support. You should not undertake new development with BDE. Consider migrating your existing database applications from BDE to dbExpress.

Database applications let users interact with the information that is stored in the databases. Databases provide structure for the information, and allow it to be shared among different applications.

Delphi provides support for relational database applications. Relational databases organize information into tables, which contain rows (records) and columns (fields). These tables can be manipulated by simple operations known as the relational calculus.

Topics

Name	Description
dbGo Overview (see page 14)	dbGo provides the developers with a powerful and logical object model for programmatically accessing, editing, and updating data from a wide variety of data sources through OLE DB system interfaces. The most common usage of dbGo is to query a table or tables in a relational database, retrieve and display the results in an application, and perhaps allow users to make and save changes to the data. When you deploy a database application that uses dbExpress, you include a DLL(the server-specific driver) with the application files you build. dbExpress lets you access databases using unidirectional datasets. Unidirectional datasets are designed for quick lightweight access to database information, with minimal overhead. Like other datasets, they can send an SQL command to the database server, and if the command returns a set... more (see page 16)
Getting Started with InterBase Express (see page 17)	InterBase Express (IBX) is a set of data access components that provide a means of accessing data from InterBase databases. The InterBase Administration Components, which require InterBase, are described after the InterBase data access components.

dbExpress 4 Feature Overview (see page 22)	dbExpress's top level framework and metadata support has been rewritten in Delphi for RAD Studio 2007. It has new, richer metadata support. The DbxClient driver remotes the dbExpress 4 framework interface over a network based transport. This document discusses the following features: • dbExpress Framework • dbExpress Metadata Improvements • DBXClient Driver • DBXDynalink Driver • DBTest
Blackfish SQL Overview (see page 24)	The design and implementation of Blackfish SQL emphasizes database performance, scalability, ease of use, and a strong adherence to industry standards. Blackfish SQL capabilities include the following: • Industry standards compliance • Entry level SQL-92 • Unicode storage of character data • Unicode-based collation key support for sorting and indexing • dbExpress 4 drivers for win32 Delphi and C++ • ADO.NET 2.0 providers for .NET • JDBC for Java • JavaBean data access components for Java • XA/JTA Distributed transactions for Java • High performance and scalability for demanding online transaction processing (OLTP) and decision support system (DSS) applications • Delphi, C#, and VB.NET stored procedures and triggers... more (see page 24)
dbExpress Framework (see page 26)	The dbExpress framework (DBX framework) is a set of abstract classes provided in the unit DBXCommon. Applications can interface with the framework in several ways: using the framework directly for both native and managed applications, and using the dbExpress VCL components that are layered on top of the framework for both native and managed applications. Although many applications interface with dbExpress drivers via the dbExpress VCL components, the DBX framework offers a convenient, lighter weight option to communicate with a database driver. You can also create a database driver for dbExpress by extending the frameworks's DBXCommon abstract... more (see page 26)
dbExpress Framework Compatibility (see page 27)	Some dbExpress software developed prior to the dbExpress driver framework (DBX driver framework) has been modified to work with the DBX driver framework. As a result of these changes, some compatibility issues arise.

1.2.1 dbGo Overview

dbGo provides the developers with a powerful and logical object model for programmatically accessing, editing, and updating data from a wide variety of data sources through OLE DB system interfaces. The most common usage of dbGo is to query a table or tables in a relational database, retrieve and display the results in an application, and perhaps allow users to make and save changes to the data.

The ADO layer of an ADO-based application consists of the latest version of Microsoft ADO, an OLE DB provider or ODBC

driver for the data store access, client software for the specific database system used (in the case of SQL databases), a database back-end system accessible to the application (for SQL database systems), and a database. All of these must be accessible to the ADO-based application for it to be fully functional.

The **dbGo** category of the **Tool Palette** hosts the **dbGo** components. These components let you connect to an ADO data store, execute commands, and retrieve data from tables in databases using the ADO framework. The components require the latest version of ADO to be installed on the host computer. Additionally, client software for the target database system (such as Microsoft SQL Server) must be installed, as well as an OLE DB driver or ODBC driver specific to the particular database system.

Most **dbGo** components have direct counterparts in the components available for other data access mechanisms: a database connection component, **TADOConnection**, and various types of datasets. In addition, **dbGo** includes **TADOCommand**, a simple component that is not a dataset but which represents an SQL command to be executed on the ADO data store.

The main **dbGo** components are:

Components	Function
TADOConnection	A database connection component that establishes a connection with an ADO data store. Multiple ADO dataset and command components can share this connection to execute commands, retrieve data, and operate on metadata.
TRDSConnection	A database connection component to marshal data in multi-tier database applications that are built using ADO-based application servers.
TADODataSet	Primary dataset used for retrieving and operating on data. **TADODataSet** can retrieve data from a single or multiple tables, can connect directly to a data store, or use a **TADOConnection** component
TADOTable	A table-type dataset for retrieving and operating on a recordset produced by a single database table. **TADOTable** can connect directly to a data store or use a **TADOConnection** component
TADOQuery	A query-type dataset for retrieving and operating on a recordset produced by a valid SQL statement. **TADOQuery** can also execute Data Definition Language (DDL) SQL statements. It can connect directly to a data store or use a **TADOConnection** component.
TADOStoredProc	A stored procedure-type dataset for executing stored procedures. **TADOStoredProc** executes stored procedures that may or may not retrieve data. It can connect directly to a data store or use a **TADOConnection** component.
TADOCommand	A simple component for executing commands (SQL statements that do not return result sets). **TADOCommand** can be used with a supporting dataset component, or retrieve a dataset from a table. It can connect directly to a data store or use a **TADOConnection** component

Working with dbGo Components (see page 1494)

1.2.2 BDE Overview

Warning: The Borland Database Engine (BDE) has been deprecated, so it will not be enhanced. For instance, BDE will never have Unicode support. You should not undertake new development with BDE. Consider migrating your existing database applications from BDE to dbExpress.

The Borland Database Engine (BDE) is a data-access mechanism that can be shared by several applications. The BDE defines a powerful library of API calls that can create, restructure, fetch data from, update, and otherwise manipulate local and remote database servers. The BDE provides a uniform interface to access a wide variety of database servers, using drivers to connect to different databases. The components on the **BDE** category of the **Tool Palette** enable you to connect to database information

using the BDE.

When deploying BDE-based applications, you must include the BDE with your application. While this increases the size of the application and the complexity of deployment, the BDE can be shared with other BDE-based applications and provides a broader range of support for database manipulation. Although you can use the API of the BDE directly in your application, the components on the **BDE** category of the **Tool Palette** wrap most of this functionality for you.

The main **BDE** components are:

Components	Function
TTable	Retrieves data from a physical database table via the BDE and supplies it to one or more data-aware components through a DataSource component. Conversely, it also sends data received from a component to a physical database via the BDE.
TQuery	Uses SQL statements to retrieve data from a physical database table via the BDE and supplies it to one or more data-aware components through a TDataSource component. Conversely, it uses SQL statements to send data from a component to a physical database via the BDE.
TStoredProc	Enables an application to access server stored procedures. It sends data received from a component to a physical database via the BDE.
TDatabase	Sets up a persistent connection to a database, especially a remote database requiring a user login and password.
TSession	Provides global control over a group of database components. A default TSession component is automatically created for each database application. You must use the TSession component only if you are creating a multithreaded database application. Each database thread requires its own session component.
TBatchMove	Copies a table structure or its data. It can be used to move entire tables from one database format to another.
TUpdateSQL	Lets you use cached updates support with read-only datasets.
TNestedTable	Retrieves the data in a nested dataset field and supplies it to data-aware controls through a datasource component.

Using BDE (see page 60)

Borland Database Engine (see page 1946)

1.2.3 dbExpress Components

dbExpress is a set of lightweight database components that provide fast access to SQL database servers. For each supported database, dbExpress provides a driver framework that adapts the server-specific software to a set of uniform dbExpress interfaces. When you deploy a database application that uses dbExpress, you include a DLL(the server-specific driver) with the application files you build.

dbExpress lets you access databases using unidirectional datasets. Unidirectional datasets are designed for quick lightweight access to database information, with minimal overhead. Like other datasets, they can send an SQL command to the database server, and if the command returns a set of records, retrieve those records. Unidirectional datasets do not buffer data in memory, which makes them faster and less resource-intensive than other types of dataset. However, because there are no buffered records, unidirectional datasets are also less flexible than other datasets.

dbExpress connections, tables, views, and stored procedures that show up in a data tree view support drag & drop with native and managed vcl forms.

The **dbExpress** category of the **Tool Palette** contains components that use **dbExpress** to access database information. They are:

Components	Function
TSQLConnection	Encapsulates a dbExpress connection to a database server
TSQLDataSet	Represents any data available through **dbExpress**, or sends commands to a database accessed through **dbExpress**
TSQLQuery	A query-type dataset that encapsulates an SQL statement and enables applications to access the resulting records, if any
TSQLTable	A table-type dataset that represents all of the rows and columns of a single database table
TSQLStoredProc	A stored procedure-type dataset that executes a stored procedure defined on a database server
TSQLMonitor	Intercepts messages that pass between an SQL connection component and a database server and saves them in a string list
TSimpleDataSet	A client dataset that uses an internal **TSQLDataSet** and **TDataSetProvider** for fetching data and applying updates

1.2.4 Getting Started with InterBase Express

InterBase Express (IBX) is a set of data access components that provide a means of accessing data from InterBase databases. The InterBase Administration Components, which require InterBase, are described after the InterBase data access components.

IBX components

The following components are located on the InterBase tab of the component palette.

	TIBTable
	TIBQuery
	TIBStoredProc
	TIBDatabase
	TIBTransaction
	TIBUpdateSQL
	TIBDataSet
	TIBSQL
	TIBDatabaseInfo
	TIBSQLMonitor

	*TIBEvents*
	TIBExtract
	TIBCustomDataSet

Though they are similar to BDE components in name, the IBX components are somewhat different. For each component with a BDE counterpart, the sections below give a discussion of these differences.

There is no simple migration from BDE to IBX applications. Generally, you must replace BDE components with the comparable IBX components, and then recompile your applications. However, the speed you gain, along with the access you get to the powerful InterBase features make migration well worth your time.

IBDatabase

Use a TIBDatabase component to establish connections to databases, which can involve one or more concurrent transactions. Unlike BDE, IBX has a separate transaction component, which allows you to separate transactions and database connections.

To set up a database connection:

1. Drop an IBDatabase component onto a form or data module.
2. Fill out the DatabaseName property. For a local connection, this is the drive, path, and filename of the database file. Set the Connected property to true.
3. Enter a valid username and password and click OK to establish the database connection.

   Warning: Tip: You can store the username and password in the IBDatabase component's Params property by setting the LoginPrompt property to false after logging in. For example, after logging in as the system administrator and setting the LoginPrompt property to false, you may see the following when editing the Params property:

```
user_name=sysdba
 password=masterkey
```

IBTransaction

Unlike the Borland Database Engine, IBX controls transactions with a separate component, TIBTransaction. This powerful feature allows you to separate transactions and database connections, so you can take advantage of the InterBase two-phase commit functionality (transactions that span multiple connections) and multiple concurrent transactions using the same connection.

Use an IBTransaction component to handle transaction contexts, which might involve one or more database connections. In most cases, a simple one database/one transaction model will do.

To set up a transaction:

1. Set up an IBDatabase connection as described above.
2. Drop an IBTransaction component onto the form or data module
3. Set the DefaultDatabase property to the name of your IBDatabase component.
4. Set the Active property to true to start the transaction.

IBX dataset components

There are a variety of dataset components from which to choose with IBX, each having their own characteristics and task suitability:

IBTable

Use an TIBTable component to set up a live dataset on a table or view without having to enter any SQL statements.

IBTable components are easy to configure:

1. Add an IBTable component to your form or data module.
2. Specify the associated database and transaction components.
3. Specify the name of the relation from the TableName drop-down list.
4. Set the Active property to true.

IBQuery

Use an TIBQuery component to execute any InterBase DSQL statement, restrict your result set to only particular columns and rows, use aggregate functions, and join multiple tables.

IBQuery components provide a read-only dataset, and adapt well to the InterBase client/server environment. To set up an IBQuery component:

1. Set up an IBDatabase connection as described above.
2. Set up an IBTransaction connection as described above.
3. Add an IBQuery component to your form or data module.
4. Specify the associated database and transaction components.
5. Enter a valid SQL statement for the IBQuery's SQL property in the String list editor.
6. Set the Active property to true

IBDataSet

Use an TIBDataSet component to execute any InterBase DSQL statement, restrict your result set to only particular columns and rows, use aggregate functions, and join multiple tables. IBDataSet components are similar to IBQuery components, except that they support live datasets without the need of an IBUpdateSQL component.

The following is an example that provides a live dataset for the COUNTRY table in employee.gdb:

1. Set up an IBDatabase connection as described above.
2. Specify the associated database and transaction components.
3. Add an IBDataSet component to your form or data module.
4. Enter SQL statements for the following properties:

SelectSQL	SELECT Country, Currency FROM Country
RefreshSQL	SELECT Country, Currency FROM Country WHERE Country = :Country
ModifySQL	UPDATE Country SET Country = :Country, Currency = :Currency WHERE Country = :Old_Country
DeleteSQL	DELETE FROM Country WHERE Country = :Old_Country
InsertSQL	INSERT INTO Country (Country, Currency) VALUES (:Country, :Currency)

1. Set the Active property to true.
2.

   Note: Note: Parameters and fields passed to functions are case-sensitive in dialect 3. For example,

```
FieldByName(EmpNo)
```

would return nothing in dialect 3 if the field was 'EMPNO'.

IBStoredProc

Use TIBStoredProc for InterBase executable procedures: procedures that return, at most, one row of information. For stored procedures that return more than one row of data, or "Select" procedures, use either IBQuery or IBDataSet components.

IBSQL

Use an TIBSQL component for data operations that need to be fast and lightweight. Operations such as data definition and pumping data from one database to another are suitable for IBSQL components.

In the following example, an IBSQL component is used to return the next value from a generator:

1. Set up an IBDatabase connection as described above.
2. Put an IBSQL component on the form or data module and set its Database property to the name of the database.
3. Add an SQL statement to the SQL property string list editor, for example:

```
SELECT GEN_ID(MyGenerator, 1) FROM RDB$DATABASE
```

IBUpdateSQL

Use an TIBUpdateSQL component to update read-only datasets. You can update IBQuery output with an IBUpdateSQL component:

1. Set up an IBQuery component as described above.
2. Add an IBUpdateSQL component to your form or data module.
3. Enter SQL statements for the following properties: DeleteSQL, InsertSQL, ModifySQL, and RefreshSQL.
4. Set the IBQuery component's UpdateObject property to the name of the IBUpdateSQL component.
5. Set the IBQuery component's Active property to true.

IBSQLMonitor

Use an TIBSQLMonitor component to develop diagnostic tools to monitor the communications between your application and the InterBase server. When the TraceFlags properties of an IBDatabase component are turned on, active TIBSQLMonitor components can keep track of the connection's activity and send the output to a file or control.

A good example would be to create a separate application that has an TIBSQLMonitor component and a Memo control. Run this secondary application, and on the primary application, activate the TraceFlags of the IBDatabase component. Interact with the primary application, and watch the second's memo control fill with data.

IBDatabaseInfo

Use an TIBDatabaseInfo component to retrieve information about a particular database, such as the sweep interval, ODS version, and the user names of those currently attached to this database.

For example, to set up an IBDatabaseInfo component that displays the users currently connected to the database:

1. Set up an IBDatabase connection as described above.
2. Put an IBDatabaseInfo component on the form or data module and set its Database property to the name of the database.
3. Put a Memo component on the form.
4. Put a Timer component on the form and set its interval.
5. Double click on the Timer's OnTimer event field and enter code similar to the following:

```
Memo1.Text := IBDatabaseInfo.UserNames.Text;   //  Delphi example
Memo1->Text = IBDatabaseInfo->UserNames->Text; //  C++ example
```

IBEvents

Use an *IBEvents* component to register interest in, and asynchronously handle, events posted by an InterBase server.

To set up an IBEvents component:

1. Set up an IBDatabase connection as described above.
2. Put an IBEvents component on the form or data module and set its Database property to the name of the database.
3. Enter events in the Events property string list editor, for example:

```
IBEvents.Events.Add('EVENT_NAME');   //  Delphi example
    IBEvents->Events->Add("EVENT_NAME"); //  C++ Example
```

1. 4. Set the Registered property to true.

2. **InterBase Administration Components**

If you have InterBase installed, you can use the InterBase Administration components, which allow you to use access the powerful InterBase Services API calls.

The components are located on the InterBase Admin tab of the IDE and include:

	TIBConfigService
	TIBBackupService
	TIBRestoreService
	TIBValidationService
	TIBStatisticalService
	TIBLogService
	TIBSecurityService
	TIBLicensingService
	TIBServerProperties
	TIBInstall
	TIBUnInstall

Note: You must install InterBase to use these features.

IBConfigService

Use an TIBConfigService object to configure database parameters, including page buffers, async mode, reserve space, and sweep interval.

IBBackupService

Use an TIBBackupService object to back up your database. With IBBackupService, you can set such parameters as the blocking factor, backup file name, and database backup options.

IBRestoreService

Use an TIBRestoreService object to restore your database. With IBRestoreService, you can set such options as page buffers, page size, and database restore options.

IBValidationService

Use an TIBValidationService object to validate your database and reconcile your database transactions. With the IBValidationService, you can set the default transaction action, return limbo transaction information, and set other database validation options.

IBStatisticalService

Use an TIBStatisticalService object to view database statistics, such as data pages, database log, header pages, index pages, and system relations.

IBLogService

Use an TIBLogService object to create a log file.

IBSecurityService

Use an TIBSecurityService object to manage user access to the InterBase server. With the IBSecurityService, you can create, delete, and modify user accounts, display all users, and set up work groups using SQL roles.

IBLicensingService

Use an TIBLicensingService component to add or remove InterBase software activation certificates.

IBServerProperties

Use an TIBServerProperties component to return database server information, including configuration parameters, and version and license information.

IBInstall

Use an TIBInstall component to set up an InterBase installation component, including the installation source and destination directories, and the components to be installed.

IBUnInstall

Use an TIBUnInstall component to set up an uninstall component.

1.2.5 dbExpress 4 Feature Overview

dbExpress's top level framework and metadata support has been rewritten in Delphi for RAD Studio 2007. It has new, richer metadata support.

The DbxClient driver remotes the dbExpress 4 framework interface over a network based transport.

This document discusses the following features:

- dbExpress Framework
- dbExpress Metadata Improvements
- DBXClient Driver
- DBXDynalink Driver
- DBTest

dbExpress Framework

VCL

The dbExpress VCL component's implementation has changed with minimal change to the API. Most applications are not affected by changes to the dbExpress VCL. However, there are some new methods, properties, events, constants, and enums.

dbExpress Metadata Improvements

New metadata providers for 9 different database backends are written completely in Delphi. Full source code to all metadata providers is included in the product.

Metadata read and write capabilities

Each provider is composed of a metadata reader and metadata writer implementation contained inside the dbExpress driver packages. The separate metadata readers and writers that were in the DbxReadOnlyMetaData and DbxMetaData packages no longer exist.

Provider based approach

The metadata providers are detached from the driver, so that one metadata provider can be used for multiple driver implementations as long as the database backend is the same. Data Explorer also takes advantage of metadata providers to provide metadata support for other database drivers.

The provider is not bound to a driver, but to a database back end. There is a new property called

TDBXPropertyNames.MetaDataPackageLoader in the dbxdrivers.ini files that can be set to a TDBXCommandFactory object. This command factory implementation creates a TDBXCommand that can execute metadata commands. This approach allows multiple driver implementations for a specific database backend to use the same metadata provider. Data Explorer also takes advantage of this architecture to provide dbExpress 4 structured metadata for drivers from other vendors. The decoupling of driver and metadata provider also benefits "thin" driver implementations. If metadata commands can be serviced on a server, there is no need to have the metadata provider logic on the client.

Provider source directory

All database source is now contained in the following installation location:

```
C:\Program FIles \ CodeGear\ RAD Studio \ 6.0 \ source \ database
```

Reading metadata

The unit DBXMetaDataNames has been provided to read metadata. The dbExpress class TDBXMetaDataCommands provides a set of constants to read various types of metadata. Set the TDBXCommand.CommandType property to TDBXCommandTypes.DBXMetadata and set TDBXCommand.Text to one of the constants in TDBXMetaDataCommands to acquire the designated metadata. TDBXCommand.ExecuteQuery returns a TDBXReader to access the metadata. The new classes in DBXMetaDataNames describe and provide access to this metadata's columns.

Writing metadata

Support for creating SQL dialect sensitive CREATE, ALTER, and DROP statements is provided in Data Explorer. dbExpress also exposes a DbxMetaDataProvider class that surfaces this capability for applications. This slightly increases the size of application, since the metadata writers must be included. The ability to generically create tables is useful for many applications. The interface allows you to describe what a table and its columns look like and pass this description to the TdbxMetaDataProvider.CreateTable method. Here is a simple example that shows how to create a table with an int32 column named "C1", a decimal with a precision of 10 and scale of 2 named "C2", and a character based column with a precision of 32 named "C3".

```
var MetaDataTable: TDBXMetaDataTable; DataGenerator: TDbxDataGenerator; Command:
    TDBXCommand; Row: Integer; begin MetaDataTable := TDBXMetaDataTable.Create;
    MetaDataTable.TableName := 'QCXXX_TABLE';
MetaDataTable.AddColumn(TDBXInt32Column.Create('C1'));
    MetaDataTable.AddColumn(TDBXDecimalColumn.Create('C2', 10, 2));
    MetaDataTable.AddColumn(TDBXUnicodeCharColumn.Create('C3', 32));
    MetaDataProvider.CreateTable(MetaDataTable); end
```

Deployment

For information about deploying database applications, see dapdeployingdatabaseapplications.xml (see page 1948).

Compatibility

The VCL components in the SqlExpr unit still work with drivers that provide the more limited dbExpress 3 metadata. However, Data Explorer only works with dbExpress 4 metadata.

Note that Delphi includes metadata for 9 different database backends. Thus any dbExpress driver implementation for the 9 backends supported can reuse the metadata provider with their driver implementation.

DBXClient Driver

DBXClient is a thin dbExpress 4 driver that remotes the dbExpress 4 framework interface over a pluggable network based transport. In this release, a TCP/IP transport is supported. The driver uses a JSON/RPC (Java Script Object Notation) based streaming protocol.

The DBXClient is implemented in 100% Object Pascal. Its source code is included in the product.

Connectivity

DBXClient can connect to Blackfish SQL and DataSnap. Blackfish SQL is a Delphi version of JBuilder's JDataStore. DataSnap provides a middle-tier application server that contains and manages remote data modules. DataSnap has been enhanced to provide a very general connection mechanism between components in different tiers.

To use the DBXClient driver with Blackfish SQL or DataSnap, add the **DBXClient** unit to the **uses** clause.

Deployment

DBXClient needs no database client library installed when you deploy your application. DBXClient is 100% Delphi and can be directly linked into your application as a single .exe file.

For further information about deploying database applications, see dapdeployingdatabaseapplications.xml (see page 1948).

DBTest

This is a collection of classes that extend the capabilities of Dunit to facilitate database testing. The qcreport and cts sample Dunit tests provide good examples of how to make use of DBTest. TestCaseExtension contains non-database related extensions to Dunit and the DBXTest unit contains database related extensions.

Command line properties

New units have been added to the DbxDynalinkDriver package for all 8 of Dynalink drivers:

Test selection

-s:<TestName> command line can be used to execute just a single method in a Dunit test case. This is useful for debugging a single bug. See the **TestCaseExtension** unit.

Convenience methods

There are several methods for creating default connection and metadata provider. See the DBXTest unit.

Data generator

There is a simple, extensible data generator. See the DBXDataGenerator unit.

1.2.6 Blackfish SQL Overview

The design and implementation of Blackfish SQL emphasizes database performance, scalability, ease of use, and a strong adherence to industry standards. Blackfish SQL capabilities include the following:

- Industry standards compliance
- Entry level SQL-92
- Unicode storage of character data
- Unicode-based collation key support for sorting and indexing
- dbExpress 4 drivers for win32 Delphi and C++
- ADO.NET 2.0 providers for .NET

- JDBC for Java
- JavaBean data access components for Java
- XA/JTA Distributed transactions for Java
- High performance and scalability for demanding online transaction processing (OLTP) and decision support system (DSS) applications
- Delphi, C#, and VB.NET stored procedures and triggers for Windows
- Java-stored procedures and triggers
- Zero-administration, single assembly or single-jar deployment
- Database incremental backup and failover

Blackfish SQL DataStore

Blackfish SQL is the name of the product, its tools, and of the file format. Within this product, there is a datastore package that includes a DataStore class, as well as several additional classes that have DataStore as part of their names.

Blackfish SQL Compatibility

Blackfish SQL for Windows and Blackfish SQL for Java are highly compatible with one another. The database file format is binary-compatible between Blackfish SQL for Windows and Blackfish SQL for Java. In addition, database clients and servers are interchangeable. Windows clients can connect to Java servers and Java clients can connect to Windows servers.

Because the Blackfish SQL for Windows implementation is more recent, some Blackfish SQL for Java features are not yet supported. The following features are not supported:

- ISQL SQL Command Line Interpreter
- High Availability features, including incremental backup and failover
- Graphical tooling for administrative capabilities
- Access to file and object streams
- Tracking and resolving of row-level insert, update and delete operations
- Access to the Blackfish SQL File System directory

Blackfish SQL Connectivity

This section provides an overview of the connection drivers provided for Blackfish SQL for Windows and Blackfish SQL for Java, respectively. For instructions on using the drivers to connect to a Blackfish SQL database, see the Blackfish SQL Developer's Guide, Establishing Connections section

Blackfish SQL for Windows Connectivity

Blackfish SQL for Windows provides the following connection drivers:

- **DBXClient:** This is a win32 dbExpress 4 database driver that enables win32 Delphi and C++ applications to connect to a remote Blackfish SQL for Windows or Blackfish SQL for Java server.
- **Local ADO.NET 2.0 Provider:** This is a 100% managed code driver that enables .NET applications to connect to a local Blackfish SQL for Windows server. The local ADO.NET driver executes in the same process as the BlackFishSQL database kernel, for greater performance.
- **Remote ADO.NET 2.0 Provider:** This is a 100% managed code driver that enables .NET applications to acquire a remote connection to either a Blackfish SQL for Windows or Blackfish SQL for Java server.

Blackfish SQL for Java Connectivity

Blackfish SQL for Java provides the following JDBC connection drivers:

- **Local JDBC driver:** This is a 100% managed code driver that enables Java applications to connect to a local Blackfish SQL

for Java server. The local JDBC driver executes in the same process as the BlackFishSQL database kernel, for greater performance.

- **Remote JDBC driver:** This is a 100% managed code driver that enables Java applications to acquire a remote connection to either a Blackfish SQL for Windows or Blackfish SQL for Java server.

1.2.7 dbExpress Framework

The dbExpress framework (DBX framework) is a set of abstract classes provided in the unit DBXCommon. Applications can interface with the framework in several ways: using the framework directly for both native and managed applications, and using the dbExpress VCL components that are layered on top of the framework for both native and managed applications.

Although many applications interface with dbExpress drivers via the dbExpress VCL components, the DBX framework offers a convenient, lighter weight option to communicate with a database driver. You can also create a database driver for dbExpress by extending the frameworks's DBXCommon abstract base classes. The DBX framework provides most commonly needed database driver functionality for a "set" oriented database application, yet provides a simple interface.

Here are some of the key features of the DBX framework:

- The driver framework is written entirely in Delphi and allows drivers to be written in Delphi.
- It uses strongly typed data access instead of pointers. For instance, it uses String types rather than pointers to strings.
- The driver framework is single sourced. You can compile the source with the native DCC32 compiler.
- The framework has only Abstract base classes that are used for drivers, connections, commands, readers, and so on.
- The framework uses exception based error handling rather than returning error codes.

Capabilities

There are two categories of drivers that extend the classes in DBXCommon: DBXDynaLink and DBXDirect. These drivers differ from each other in the way they are loaded and the capabilities they provide to an application. These are described in greater detail later.

You can also extend the DBX framework to write *delegation drivers*, which provide an extra layer between the application and the actual driver. Delegate drivers are useful for connection pooling, driver profiling, tracing, and auditing. Another possible application of driver delegation is to create a thread safe driver delegate. Such a delegate could provide thread synchronized access to all public methods.

Absolute thread safety is left to applications using dbExpress. However, some thread safety issues are best handled by the dbExpress framework. dbExpress thread safe operations include loading and unloading drivers, and connection creation. As mentioned earlier, a delegate driver can be created to make the entire public interface of dbExpress thread safe if needed.

A dbExpress 4 driver can statically or dynamically link drivers built as Delphi packages. The easiest way to link a driver package is to just include it in the "uses" clause. The driver loader also loads packages specified in a config or ini file using the LoadPackage method. This allows dynamic loading of drivers that are never specified in a uses clause of any of the application's units. Note that the LoadPackage approach can only be employed for applications built to use packages.

dbExpress 4 driver writers should examine the initialization sections of the DBXDynalink and DBXTrace units in the source code provided with dbExpress. These sections register themselves with a singleton unit called the ClassRegistry. The ClassRegistry is used by the dbExpress 4 driver loader to instantiate driver loader classes by name (a String). The ClassRegistry is a simple, lightweight mechanism for registering and instantiating a class by name.

DBXDynalink Drivers

DBXDynalink is used for existing dbExpress 3 drivers as well as new drivers. It is compiled as a native Delphi package. DBXDynalink loads native dbExpress drivers that implement a more primitive "native" interface called DBXExports. The DBXExports interface is a small collection of "flat" export methods. DBXExports's source is included with dbExpress. DBXExports provides a more strongly typed API than the dbExpress 3's COM based interface. This allows methods to be added in future product generations without breaking compatibility with older implementations of the DBXExports interface.

DBXAdapter is a dbExpress 4 compliant driver that adapts the DBXExports interface to the older dbExpress 3 COM interface. Newer native drivers can be written by implementing DBXExports directly.

Because the DBXExports interface is designed to be implemented using any native language (Delphi or C++), it uses more primitive, non-exception based error handling. DBXDynalink maps error codes to a DBXCommon exception.

The DBXDynalink unit contains a dbExpress 4 driver. This driver delegates to non-Delphi drivers that implement the DBXDynalinkExport flat export interface. DBXTrace is a delegate driver used for tracing. The dbExpress VCL uses DBXCommon, DBXDynalink and DbxTrace as "default" drivers. However, this can be changed for statically linked applications without modifying dbExpress VCL source code (SQLExpr.pas). SQLExpr.pas uses the unit DBXDefaultDrivers. The DBXDefaultDrivers unit only contains a uses clause. The DBXDefaultDrivers uses clause contains DBXCommon, DBXDynalink, and DBXTrace. DBXCommon must always be used. However, a statically linked application could remove DBXTrace and replace DBXDynalink with a different driver.

DBXDirect Drivers

A DBXDirect driver is any driver that is implemented by extending the DBXCommon abstract base classes. These classes are written in Delphi for native implementations.

Strictly speaking, all DBX framework drivers are a form of DBXDirect driver. However DBXDynalink and DBXRemote provide a more "indirect" linkage to driver implementations.

Deploying dbExpress Database Applications (see page 1942)

1.2.8 dbExpress Framework Compatibility

Some dbExpress software developed prior to the dbExpress driver framework (DBX driver framework) has been modified to work with the DBX driver framework. As a result of these changes, some compatibility issues arise.

General

dbExpress 2.5 drivers *cannot* be used with the DBX framework.

The dbExpress framework does not provide 100% compatibility with dbExpress 3.

dbExpress 3 drivers can be used with the DBX framework. The DBX framework driver loader automatically detects dbExpress 3 drivers and uses the DBXAdapter driver (dbxadapter30.dll) to make a dbExpress 3 driver look like a dbExpress 4 driver.

Here is a list of known compatibility issues:

- Static driver linkage. You cannot statically link dbExpress drivers into an executable.
- SqlExpr.TSQLConnection provided protected access to the Connection member that was of type TISQLConnection only in the native version of SqlExpr.pas. This was omitted from the managed version due to the complexity of how PInvoke was used in the managed version of the dbExpress VCL. SqlExpr.TSQLConnection now provides protected access to a TDBXConnection instead. This protected connection is accessible to both native and managed applications.

- The event for trace monitoring is slightly different because it is based on the DBX driver framework.
- The DBXadapter driver can adapt dbExpress 3 drivers to dbExpress 4, but not dbExpress 2.5 drivers.

VCL issues

Most applications using dbExpress VCL components should work without modification. However, there are some localized changes to VCL components due to VCL now interfacing to the more object oriented DBX driver framework instead of the C-like COM-based dbExpress 3 driver interface.

In addition, the API has changed slightly for two of the VCL components: TSQLConnection and TSQLDataSet. Some data structures have also changed. A summary of the API changes follows.

Note: Because of API changes, you must recompile SqlExpr.pas, which is provided with the product. The DBXpress unit has been deprecated.

- TSQLConnection. The Commit method has been deprecated in favor of the new CommitFreeAndNil method. The Rollback method has been deprecated in favor of the new RollbackFreeAndNil and RollbackIncompleteFreeAndNil methods. The SetTraceCallbackEvent method has been replaced by SetTraceEvent. The StartTransaction method has been deprecated in favor of the new BeginTransaction method. The MetaData property contains an instance of the new class TDBXDatabaseMetaData instead of TISQLMetaData. The SQLConnection property has been replaced by DBXConnection, which contains an instance of the new class TDBXConnection. The TraceCallbackEventproperty now contains a TDBXTraceEvent.
- TSQLDataSet. A new property DbxCommandType has been added, which contains one of the constant strings in the TDBXCommandTypes class.
- Data structures. TTransactionItem has been deprecated, replaced by the new TDBXTransaction class. TSQLDriverOption, TSQLConnectionOption, TSQLCommandOption, TSQLCursorOption, TSQLMetaDataOption, and TSQLObjectType are obsolete. TSTMTParamType has been replaced by the TDBXParameterDirections class. TSQLTraceFlag has been replaced by TDBXTraceFlags. SQLTRACEDesc is replaced by TDBXTraceInfo.

1.3 Developing Interoperable Applications

RAD Studio provides wizards and classes to make it easy to implement applications based on the Component Object Model (COM) from Microsoft. With these wizards, you can create COM-based classes and components to use within applications or you can create fully functional COM clients or servers that implement COM objects, Automation servers (including Active Server Objects), ActiveX controls, or ActiveForms.

Topics

Name	Description
Developing COM Applications (see page 29)	Delphi provides wizards and classes to make it easy to implement applications based on the Component Object Model (COM) from Microsoft. With these wizards, you can create COM-based classes and components to use within applications or you can create fully functional COM clients and servers that implement COM objects, Automation servers (including Active Server Objects), ActiveX controls, or ActiveForms. This topic covers: • COM Technologies Overview • COM Interfaces • COM Servers • COM Clients

1.3.1 Developing COM Applications

Delphi provides wizards and classes to make it easy to implement applications based on the Component Object Model (COM) from Microsoft. With these wizards, you can create COM-based classes and components to use within applications or you can create fully functional COM clients and servers that implement COM objects, Automation servers (including Active Server Objects), ActiveX controls, or ActiveForms.

This topic covers:

- COM Technologies Overview
- COM Interfaces
- COM Servers
- COM Clients

COM Technologies Overview

COM is a language-independent software component model that enables interaction between software components and applications running on a Windows platform. The most important aspect of COM is that it enables communication between components, between applications, and between clients and servers through clearly defined interfaces. Interfaces provide a way for clients to ask a COM component which features it supports at runtime. To provide additional features for your component, you simply add an additional interface for those features.

Applications can access the interfaces of COM components that exist on the same computer as the application or that exist on another computer on the network using a mechanism called Distributed COM (DCOM).

COM is both a specification and an implementation. The COM specification defines how objects are created and how they communicate with each other. According to this specification, COM objects can be written in different languages, run in different

process spaces and on different platforms. As long as the objects conform to the written specification, they can communicate. This allows you to integrate legacy code as a component with new components implemented in object-oriented languages.

The COM implementation is built into the Win32 subsystem, which provides a number of core services that support the specification. The COM library contains a set of standard interfaces that define the core functionality of a COM object, and a small set of API functions for creating and managing COM objects.

When you use Delphi wizards and VCL objects in your application, you are using Delphi's implementation of the COM specification. In addition, Delphi provides some wrappers for COM services for those features that it does not implement directly (such as Active Documents). You can find these wrappers defined in the `ComObj` unit and the API definitions in the `AxCtrls` unit.

Note: Delphi's interfaces and language follow the COM specification. Delphi implements objects conforming to the COM spec using a set of classes called the Delphi ActiveX framework (DAX). These classes are found in the `AxCtrls`, `OleCtrls`, and `OleServer` units. In addition, the Delphi interface to the COM API is in `ActiveX.pas` and `ComSvcs.pas`.

COM Interfaces

COM clients communicate with objects through COM interfaces. Interfaces are groups of logically or semantically related routines which provide communication between a provider of a service (server object) and its clients.

For example, every COM object must implement the basic interface, `IUnknown`. Through a routine called `QueryInterface` in `IUnknown`, clients can request other interfaces implemented by the server.

Objects can have multiple interfaces, where each interface implements a feature. An interface provides a way to tell the client what service it provides, without providing implementation details of how or where the object provides this service.

Key aspects of COM interfaces are as follows:

- Once published, interfaces do not change. You can rely on an interface to provide a specific set of functions. Additional functionality is provided by additional interfaces.
- By convention, COM interface identifiers begin with a capital I and a symbolic name that defines the interface, such as `IMalloc` or `IPersist`.
- Interfaces are guaranteed to have a unique identification, called a Globally Unique Identifier (GUID), which is a 128-bit randomly generated number. Interface GUIDs are called Interface Identifiers (IIDs). This eliminates naming conflicts between different versions of a product or different products.
- Interfaces are language independent. You can use any language to implement a COM interface as long as the language supports a structure of pointers, and can call a function through a pointer, either explicitly or implicitly.
- Interfaces are not objects themselves, they provide a way to access an object. Therefore, clients do not access data directly, they access data through an interface pointer. Windows 2000 adds another layer of indirection, known as an interceptor, through which it provides COM+ features such as just-in-time activation and object pooling.
- Interfaces are always inherited from the base interface, `IUnknown`.
- Interfaces can be redirected by COM through proxies to enable interface method calls to call between threads, processes, and networked machines, all without the client or server objects ever being aware of the redirection.

The IUnknown interface

All COM objects must support the fundamental interface, called `IUnknown`, a typedef to the base interface type `IInterface`. `IUnknown` contains the following routines:

- `QueryInterface`: Provides pointers to other interfaces that the object supports.
- `AddRef` and `Release`: Simple reference counting methods that keep track of the object's lifetime so that an object can delete itself when the client no longer needs its service.

Clients obtain pointers to other interfaces through the `IUnknown` method, `QueryInterface`. `QueryInterface` knows about every interface in the server object and can give a client a pointer to the requested interface. When receiving a pointer to an

interface, the client is assured that it can call any method of the interface.

Objects track their own lifetime through the `IUnknown` methods, `AddRef` and `Release`, which are simple reference counting methods. As long as the reference count of an object is nonzero, the object remains in memory. Once the reference count reaches zero, the interface implementation can safely dispose of the underlying object.

COM Interface Pointers

An interface pointer is a pointer to an object instance that points, in turn, to the implementation of each method in the interface. The implementation is accessed through an array of pointers to these methods, which is called a vtable. Vtables are similar to the mechanism used to support virtual functions in Delphi. Because of this similarity, the compiler can resolve calls to methods on the interface the same way it resolves calls to methods on Delphi classes.

The vtable is shared among all instances of an object class, so for each object instance, the object code allocates a second structure that contains its private data. The client's interface pointer, then, is a pointer to the pointer to the vtable.

In Windows 2000 and subsequent versions of Windows, when an object is running under COM+, another level of indirection is provided between the interface pointer and the vtable pointer. The interface pointer available to the client points at an interceptor, which in turn points at the vtable. This allows COM+ to provide such services as just-in-time activation, where the server can be deactivated and reactivated dynamically in a way that is opaque to the client. To achieve this, COM+ guarantees that the interceptor behaves as if it were an ordinary vtable pointer.

COM Servers

A COM server is an application or a library that provides services to a client application or library. A COM server consists of one or more COM objects, where a COM object is a set of properties and methods.

Clients do not know how a COM object performs its service; the object's implementation remains hidden. An object makes its services available through its interfaces as described previously.

In addition, clients do not need to know where a COM object resides. COM provides transparent access regardless of the object's location.

When a client requests a service from a COM object, the client passes a class identifier (CLSID) to COM. A CLSID is simply a GUID that identifies a COM object. COM uses this CLSID, which is registered in the system registry, to locate the appropriate server implementation. Once the server is located, COM brings the code into memory, and has the server create an object instance for the client. This process is handled indirectly, through a special object called a class factory (based on interfaces) that creates instances of objects on demand.

As a minimum, a COM server must perform the following:

- Register entries in the system registry that associate the server module with the class identifier (CLSID).
- Implement a class factory object, which creates another object of a particular CLSID.
- Expose the class factory to COM.
- Provide an unloading mechanism through which a server that is not servicing clients can be removed from memory.

COM Clients

COM clients are applications that make use of a COM object implemented by another application or library. The most common types are Automation controllers, which control an Automation server and ActiveX containers, which host an ActiveX control.

There are two types of COM clients, controllers and containers. Controllers launch the server and interact with it through its interface. They request services from the COM object or drive it as a separate process. Containers host visual controls or objects that appear in the container's user interface. They use predefined interfaces to negotiate display issues with server objects. It is impossible to have a container relationship over DCOM; for example, visual controls that appear in the container's user interface must be located locally. This is because the controls are expected to paint themselves, which requires that they have access to local GDI resources.

The task of writing these two types of COM client is remarkably similar: The client application obtains an interface for the server

object and uses its properties and methods. Delphi makes it easier for you to develop COM clients by letting you import a type library or ActiveX control into a component wrapper so that server objects look like other VCL components. Delphi lets you wrap the server `CoClass` in a component on the client, which you can even install on the Component palette. Samples of such component wrappers appear on two pages of the Component palette, sample ActiveX wrappers appear on the ActiveX page, and sample Automation objects appear on the Servers page.

Even if you do not choose to wrap a server object in a component wrapper and install it on the Component palette, you must make its interface definition available to your application. To do this, you can import the server's type information.

Clients can always query the interfaces of a COM object to determine what it is capable of providing. All COM objects allow clients to request known interfaces. In addition, if the server supports the `IDispatch` interface, clients can query the server for information about what methods the interface supports. Server objects have no expectations about the client using its objects. Similarly, clients don't need to know how an object provides the services, they simply rely on server objects to provide the services they describe in their interfaces.

COM Extensions

As COM has evolved, it has been extended beyond the basic COM services. COM serves as the basis for other technologies such as Automation, ActiveX controls, Active Documents, and Active Directories. In addition, when working in a large, distributed environment, you can create transactional COM objects. Prior to Windows 2000, these objects were not an architectural part of COM, but ran in the Microsoft Transaction Server (MTS) environment. As of Windows 2000, this support is integrated into COM+. Delphi provides wizards to easily implement applications that use the above technologies in the Delphi environment.

Automation Servers

Automation refers to the ability of an application to control the objects in another application programmatically, such as a macro that can manipulate more than one application at the same time. The server object being manipulated is called the Automation object, and the client of the Automation object is referred to as an Automation controller. Automation can be used on in-process, local, and remote servers.

Automation is defined by two major points:

- The Automation object defines a set of properties and commands, and describes their capabilities through type descriptions. In order to do this, it must have a way to provide information about its interfaces, the interface methods, and the arguments to those methods. Typically, this information is available in a type library. The Automation server can also generate type information dynamically when queried via its `IDispatch` interface.
- Automation objects make their methods accessible so that other applications can use them. For this, they implement the `IDispatch` interface. Through this interface an object can expose all of its methods and properties. Through the primary method of this interface, the object's methods can be invoked, once having been identified through type information.

Developers often use Automation to create and use non-visual OLE objects that run in any process space, because the Automation `IDispatch` interface automates the marshaling process. Automation does, however, restrict the types that you can use.

Active X Controls

Delphi wizards allow you to easily create ActiveX controls. ActiveX is a technology that allows COM components, especially controls, to be more compact and efficient. This is especially necessary for controls that are intended for Intranet applications, which need to be downloaded by a client before they are used.

ActiveX controls are visual controls that run only as in-process servers, and can be plugged into an ActiveX control container application. They are not complete applications in themselves, but can be thought of as already written OLE controls that are reusable in various applications. ActiveX controls have a visible user interface, and rely on predefined interfaces to negotiate I/O and display issues with their host containers.

ActiveX controls make use of Automation to expose their properties, methods, and events. Features of ActiveX controls include the ability to fire events, bind to data sources, and support licensing.

One use of ActiveX controls is on a Web site as interactive objects in a Web page. As such, ActiveX is a standard that targets

interactive content for the World Wide Web, including the use of ActiveX Documents used for viewing non-HTML documents through a Web browser. For more information about ActiveX technology, see the Microsoft ActiveX Web site.

Active Documents

Active Documents (previously referred to as OLE documents) are a set of COM services that support linking and embedding, drag-and-drop, and visual editing. Active Documents can seamlessly incorporate data or objects of different formats, such as sound clips, spreadsheets, text, and bitmaps.

Unlike ActiveX controls, Active Documents are not limited to in-process servers; they can be used in cross-process applications.

Unlike Automation objects, which are almost never visual, Active Document objects can be visually active in another application. Thus, Active Document objects are associated with two types of data: presentation data, used for visually displaying the object on a display or output device, and native data, used to edit an object.

Active Document objects can be document containers or document servers. While Delphi does not provide an automatic wizard for creating Active Documents, you can use the VCL class, TOleContainer, to support linking and embedding of existing Active Documents.

You can also use TOleContainer as a basis for an Active Document container. To create objects for Active Document servers, use the COM object wizard and add the appropriate interfaces, depending on the services the object needs to support. For more information about creating and using Active Document servers, see the Microsoft ActiveX Web site.

Note: While the specification for Active Documents has built-in support for marshaling in cross-process applications, Active Documents do not run on remote servers because they use types that are specific to a system on a given machine such as window handles, menu handles, and so on.

Transactional Objects

Delphi uses the term "transactional objects" to refer to objects that take advantage of the transaction services, security, and resource management supplied by Microsoft Transaction Server (MTS) (for versions of Windows prior to Windows 2000) or COM+ (for Windows 2000 and later). These objects are designed to work in a large, distributed environment.

The transaction services provide robustness so that activities are always either completed or rolled back. The server never partially completes an activity. The security services allow you to expose different levels of support to different classes of clients. The resource management allows an object to handle more clients by pooling resources or keeping objects active only when they are in use. To enable the system to provide these services, the object must implement the `IObjectControl` interface. To access the services, transactional objects use an interface called `IObjectContext`, which is created for them by MTS or COM+.

Under MTS, the server object must be built into a DLL library, which is then installed in the MTS runtime environment. That is, the server object is an in-process server that runs in the MTS runtime process space. Under COM+, this restriction does not apply because all COM calls are routed through an interceptor. To clients, the difference between MTS and COM+ is transparent.

MTS or COM+ servers group transactional objects that run in the same process space. Under MTS, this group is called an MTS package, while under COM+ it is called a COM+ application. A single machine can be running several different MTS packages (or COM+ applications), where each one is running in a separate process space.

To clients, the transactional object may appear like any other COM server object. The client does not need know about transactions, security, or just-in-time activation unless it is initiating a transaction itself.

Both MTS and COM+ provide a separate tool for administering transactional objects. This tool lets you configure objects into packages or COM+ applications, view the packages or COM+ applications installed on a computer, view or change the attributes of the included objects, monitor and manage transactions, make objects available to clients, and so on. Under MTS, this tool is the MTS Explorer. Under COM+ it is the COM+ Component Manager.

Type Libraries

Type libraries provide a way to get more type information about an object than can be determined from an object's interface. The type information contained in type libraries provides needed information about objects and their interfaces, such as what interfaces exist on what objects (given the CLSID), what member functions exist on each interface, and what arguments those functions require.

You can obtain type information either by querying a running instance of an object or by loading and reading type libraries. With this information, you can implement a client which uses a desired object, knowing specifically what member functions you need, and what to pass those member functions.

Clients of Automation servers, ActiveX controls, and transactional objects expect type information to be available. All of Delphi's wizards generate a type library automatically, although the COM object wizard makes this optional. You can view or edit this type information by using the Type Library Editor.

1.4 Developing Reports for Your Win32 Applications

RAD Studio ships with Rave Reports from Nevrona. Using the report components, you can build full-featured reports for your applications. You can create solutions that include reporting capabilities which can be used and customized by your customers. Additionally, the ComponentOne tools that ship with RAD Studio include components for creating and generating reports.

Topics

Name	Description
Using Rave Reports in RAD Studio (see page 35)	The RAD Studio environment supports the integration of report objects in your applications. This integration allows you to create a report using the Rave Reports Designer directly from within the RAD Studio IDE. Your application users can create and display their own reports, or display existing reports.

1.4.1 Using Rave Reports in RAD Studio

The RAD Studio environment supports the integration of report objects in your applications. This integration allows you to create a report using the Rave Reports Designer directly from within the RAD Studio IDE. Your application users can create and display their own reports, or display existing reports.

Creating New Reports in RAD Studio

You can include reports in RAD Studio just as you would other 3rd-party components. The report is stored as a separate Rave Report object. You can reference the report in other applications that need to call or generate that report. When you create a new application, you can include the report object by adding a reference to it in the **Project Manager**. Rave Reports also provide the capability to connect your report object to a datasource, which allows your application to build the report dynamically, based on current database information.

Adding Rave Reports to RAD Studio (see page 81)

1.5 Developing Applications with VCL Components

The Visual Component Library (VCL) is a set of visual components for the rapid development of Windows applications in the Delphi language.

VCL contains a wide variety of visual, non-visual, and utility classes for tasks such as building Windows applications, web applications, database applications, and console applications.

Topics

Name	Description
VCL Overview (see page 36)	This section introduces: • VCL Architecture • VCL Components • Working With Components
Using TEncoding for Unicode Files (see page 38)	
Components Available Only on Specific OS (see page 39)	Some VCL components are specific to an operating system (such as Vista) and thus will not work on other operating systems. For example, the design time components TFileOpenDialog and TFileSaveDialog are specific to Vista. Some components are designed to work with themes either enabled or disabled. (To enable or disable themes, check or uncheck the Enable runtime themes box on the **Project** ▶ **Options** ▶ **Application** dialog box.) In the following table, note that Windows Server 2003 is treated as Windows XP, and Windows Server 2008 is treated as Vista. ***Components Available Only for Certain Operating Systems***

1.5.1 VCL Overview

This section introduces:

- VCL Architecture
- VCL Components
- Working With Components

VCL Architecture

VCL is an acronym for the Visual Component Library, a set of visual components for rapid development of Windows applications in the Delphi language. VCL contains a wide variety of visual, non-visual, and utility classes for tasks such as Windows application building, web applications, database applications, and console applications. All classes descend from System::TObject. System::TObject introduces methods that implement fundamental behavior like construction, destruction, and message handling.

VCL Components

Components are a subset of the component library that descend from the class TComponent. You can place components on a form or data module and manipulate them at designtime. Using the **Object Inspector**, you can assign property values without writing code. Most components are either visual or nonvisual, depending on whether they are visible at runtime. Some components appear on the **Component Palette**.

Visual Components

Visual components, such as TForm and TSpeedButton, are called controls and descend from TControl. Controls are used in GUI applications, and appear to the user at runtime. TControl provides properties that specify the visual attributes of controls, such as their height and width.

NonVisual Components

Nonvisual components are used for a variety of tasks. For example, if you are writing an application that connects to a database, you can place a TDataSource component on a form to connect a control and a dataset used by the control. This connection is not visible to the user, so TDataSource is nonvisual. At designtime, nonvisual components are represented by an icon. This allows you to manipulate their properties and events just as you would a visual control.

Other VCL Classes

Classes that are not components (that is, classes that descend from System::TObject but not TComponent) are also used for a variety of tasks. Typically, these classes are used for accessing system objects (such as a file or the clipboard) or for transient tasks (such as storing data in a list). You cannot create instances of these classes at designtime, although they are sometimes created by the components that you add in the **Form Designer**.

Working With Components

Many components are provided in the IDE on the **Component Palette**. You select components from the **Component Palette** and place them onto a form or data module. You design the user interface of an application by arranging the visual components such as buttons and list boxes on a form. You can also place nonvisual components, such as data access components, on either a form or a data module. At first, Delphi's components appear to be just like any other classes. But there are differences between components in Delphi and the standard class hierarchies that many programmers work with. Some differences are:

- All Delphi components descend from TComponent.
- Components are most often used as is. They are changed through their properties, rather than serving as base classes to be subclassed to add or change functionality. When a component is inherited, it is usually to add specific code to existing event handling member functions.
- Components can only be allocated on the heap, not on the stack.
- Properties of components contain runtime type information.
- Components can be added to the **Component Palette** in the IDE and manipulated on a form.

Components often achieve a better degree of encapsulation than is usually found in standard classes. For example, consider a dialog box containing a button. In a Windows program developed using VCL components, when a user clicks the button, the system generates a `WM_LBUTTONDOWN` message. The program must catch this message (typically in a switch statement, a message map, or a response table) and send it to a routine that will execute in response to the message. Most Windows messages (VCL applications) are handled by Delphi components. When you want to respond to a message or system event, you only need to provide an event handler.

Using Events

Almost all the code you write is executed, directly or indirectly, in response to events. An event is a special kind of property that represents a runtime occurrence, often a user action. The code that responds directly to an event, called an event handler, is a Delphi procedure.

The **Events** page of the **Object Inspector** displays all events defined for a given component. Double-clicking an event in the **Object Inspector** generates a skeleton event handling procedure, which you can fill in with code to respond to that event. Not all components have events defined for them.

Some components have a default event, which is the event the component most commonly needs to handle. For example, the default event for a button is `OnClick`. Double-clicking on a component with a default event in the **Form Designer** will generate a skeleton event handling procedure for the default event.

You can reuse code by writing event handlers that respond to more than one event. For example, many applications provide speed buttons that are equivalent to drop down menu commands. When a button performs the same action as a menu command, you can write a single event handler and then assign it to the OnClick event for both the button and the menu item by setting the event handler in the **Object Inspector** for both the events you want to respond to.

This is the simplest way to reuse event handlers. However, action lists, and in the VCL, action bands, provide powerful tools for centrally organizing the code that responds to user commands. Action lists can be used in cross-platform applications; action bands cannot.

Setting Component Properties

To set published properties at design time, you can use the **Object Inspector** and, in some cases, property editors. To set properties at runtime, assign their values in your application source code.

When you select a component on a form at design time, the **Object Inspector** displays its published properties and, when appropriate, allows you to edit them.

When more than one component is selected, the **Object Inspector** displays all properties—except `Name`—that are shared by the selected components. If the value for a shared property differs among the selected components, the **Object Inspector** displays either the default value or the value from the first component selected. When you change a shared property, the change applies to all selected components.

Changing code-related properties, such as the name of an event handler, in the **Object Inspector** automatically changes the corresponding source code. In addition, changes to the source code, such as renaming an event handler method in a form class declaration, are immediately reflected in the **Object Inspector**.

Building a VCL Forms "Hello world" Application (see page 101)

Organizing Actions for Toolbars and Menus (see page 1992)

1.5.2 Using TEncoding for Unicode Files

Reading and Writing in the Old Format

Many Delphi applications will need to continue to interact with other applications or datasources, many of which can only handle data in ANSI or ASCII. For this reason, the defaults for the TStrings methods will write the files ANSI encoded based on the active code page and will read the files based on whether or not the file contains a Byte Order Mark (BOM).

If a BOM is found, it will read the data encoded as the BOM indicates. If no BOM is found, it will read it as ANSI and up-convert based on the current active codepage.

All your files written with pre-RAD Studio 2009 versions of Delphi will still be read in, with the caveat that as long as you read with the active codepage the same as with what was written. Likewise, any file written with RAD Studio 2009 with an ASCII encoding should be readable with the pre-RAD Studio 2009 version.

Any file written with RAD Studio 2009 with any other encoding will generate a BOM and will not be readable with a the pre-RAD Studio 2009 version. At this point, only the most common BOM formats are detected (UTF16 Little-Endian, UTF16 Big-Endian and UTF8).

Using the new encodings

You may want to read/write text data using the TStrings class a loss-less Unicode format, be that Little-Endian UTF16, Big-Endian UTF16, UTF8, UTF7 so on. The TEncoding class is very similar in methods and functionality that you can find in the

System.Text.Encoding class in the .NET Framework.

```
var
  S: TStrings;
begin
  S: TStringList.Create();
  { ... }
  S.SaveToFile('config.txt', TEncoding UTF8);
```

Without the extra parameter, ‘config.txt’ would simply be converted and written out as ANSI encoded based on the current active codepage. You do not need to change the read code since TStrings will automatically detect the encoding based on the BOM and do the right thing.

If you wanted to force the file to read and write using a specific codepage, you can create an instance of TMBCSEncoding and pass in the code page you want to use into the constructor. Then you use that instance to read and write the file, since the specific codepage may not match the user’s active codepage.

The same thing holds for these classes in that the data will be read and written as ANSI data. Since INI files have always been traditionally ANSI (ASCII) encoded, it may not make sense to convert these. It will depend on the needs of your application. If you do wish to change to use a Unicode format, we will offer ways to use the TEncoding classes to accomplish that as well.

In all the above cases, the internal storage will be Unicode and any data manipulation you do with string will continue to function as expected. Conversions will automatically happen when reading and writing the data.

Here is a list of codepage identifiers (MSDN).:

The following list shows the overload methods that accept a TEncoding parameter:

- WriteNode (Outline.TOutlineNode)
- LoadFromFile (Outline.TOutlineNode)
- LoadFromStream (Outline.TOutlineNode)
- SaveToFile (Outline.TOutlineNode)
- SaveToStream (Outline.TOutlineNode)
- LoadFromFile (Classes.TStrings)
- LoadFromStream (Classes.TStrings)
- SaveToFile (Classes.TStrings)
- SaveToStream (Classes.TStrings)
- Create (Classes.TStringStream)
- Create (Classes.TStreamReader)
- Create (Classes.TStreamWriter)

1.5.3 Components Available Only on Specific OS

Some VCL components are specific to an operating system (such as Vista) and thus will not work on other operating systems. For example, the design time components TFileOpenDialog and TFileSaveDialog are specific to Vista. Some components are designed to work with themes either enabled or disabled. (To enable or disable themes, check or uncheck the Enable runtime themes box on the **Project** ▸ **Options** ▸ **Application** dialog box.)

In the following table, note that Windows Server 2003 is treated as Windows XP, and Windows Server 2008 is treated as Vista.

Components Available Only for Certain Operating Systems

Component	Windows 2000	Windows XP	Windows Vista
CheckBox, Checked, and FixedWidth properties for THeaderSection	No	No	Yes
CheckBoxes, NoSizing and OverFlow properties to THeaderControl	No	No	Yes
Group support for TListView	No	Yes	Yes
ImageList support for TButton	No	Yes	Yes
Platform Default Style for ActionMenus/ActionToolBars	Yes, standard style	Yes, XP style	Yes, Vista style
Support of transparent PNGs in TImage	Yes	Yes	Yes
TBalloonHints, Vista style	No	Yes, with themes enabled	Yes
TButton.ElevationRequired	No	No	Yes
TButton.CommandLink	No	No	Yes
TButton.SplitButton	No	No	Yes
TComboBox.TextHint	No	No	Yes
TEdit.TextHint	No	No	Yes
TGlassFrame	No	No	Yes
TImageList.ColorDepth := cd32Bit	No	Yes, with themes enabled	Yes, with themes enabled
TLabel.GlowSize (only on TGlassFrame)	No	No	Yes
TLinkLabel	No (plain text only)	Yes, with themes enabled	Yes, with themes enabled
TListView collapsible groups	No	No	Yes
TProgessBar colors and progress automatically set for state by the engines	No	Yes, with themes enabled	Yes
TProgressBar.SmoothReverse	No	No	Yes
TStaticText support HTML links in the textfield. AllowLInks property	No	Yes, with themes enabled	Yes
TTaskDialog	No	No	Yes

1.6 Developing Web Applications with WebSnap

This section provides a conceptual background for building WebSnap applications using RAD Studio. WebSnap makes it easier to build Web server applications that deliver complex, data-driven Web pages. WebSnap's support for multiple modules and for server-side scripting makes development and maintenance easier for teams of developers and Web designers.

Please note that WebSnap is being deprecated in RAD Studio. Although WebSnap is still documented in the online help, the WebSnap product is no longer fully supported. As an alternative, you should begin using IntraWeb (VCL for the Web). IntraWeb (see page 2254) is documented in this online help. For more documentation on VCL for the Web, go to http://www.atozed.com/intraweb/docs/.

Topics

Name	Description
Win32 Web Applications Overview (see page 41)	This section covers: • Web Application Support • Web Broker Overview • Web Snap Overview • Debugging With the Web Application Debugger For more detailed information on web applications, please see the Win32 Developers Guide in the Reference section of this Help system.

1.6.1 Win32 Web Applications Overview

This section covers:

- Web Application Support
- Web Broker Overview
- Web Snap Overview
- Debugging With the Web Application Debugger

For more detailed information on web applications, please see the Win32 Developers Guide in the Reference section of this Help system.

Win32 Web Application Support

The following types of web applications will be supported in RAD Studio.

- ISAPI
- CGI
- Web Application Debugger

Apache web applications are not supported for this release.

ISAPI

Selecting this type of application sets up your project as a DLL, with the exported methods expected by the Web server. It adds the library header to the project file, and the required entries to the `uses` list and `exports` clause of the project file.

CGI

Selecting this type of application sets up your project as a console application, and adds the required entries to the `uses` clause of the project file.

Web Application Debugger

Selecting this type of application sets up an environment for developing and testing Web server applications. This type of application is not intended for deployment.

Web Broker Overview

Web Broker components, located on the **Internet** tab of the **Component Palette**, enable you to create event handlers that are associated with a specific Uniform Resource Identifier (URI). When processing is complete, you can construct HTML or XML documents within your program and transfer them to the client. You can use Web Broker components for cross-platform application development.

Frequently, the content of Web pages is drawn from databases. You can use Internet components to automatically manage connections to databases, allowing a single DLL to handle multiple simultaneous, thread-safe, database connections.

Web Snap Overview

Note: WebSnap is being deprecated in RAD Studio. Although WebSnap is still documented in the online help, the WebSnap product is no longer fully supported. As an alternative, you should begin using IntraWeb (VCL for the Web). IntraWeb (see page 2254) is documented in this online help. For more documentation on VCL for the Web, go to http://www.atozed.com/intraweb/docs/.

WebSnap augments Web Broker with additional components, wizards, and views, making it easier to build Web server applications that deliver complex, data-driven Web pages. WebSnap's support for multiple modules and for server-side scripting makes development and maintenance easier for teams of developers and Web designers. WebSnap allows HTML design experts on your team to make a more effective contribution to Web server development and maintenance.

The final product of the WebSnap development process includes a series of scriptable HTML page templates. These pages can be changed using HTML editors that support embedded script tags, like Microsoft FrontPage, or even a text editor. Changes can be made to the templates as needed, even after the application is deployed. There is no need to modify the project source code at all, which saves valuable development time. WebSnap’s multiple module support can be used to divide your application into smaller pieces during the coding phases of your project, so that developers can work more independently.

Debugging With the Web Application Debugger

The Web Application Debugger provides an easy way to monitor HTTP requests, responses, and response times. The Web Application Debugger takes the place of the Web server. Once you have debugged your application, you can convert it to one of the supported types of Web application and install it with a commercial Web server.

To use the Web Application Debugger, you must first create your Web application as a Web Application Debugger executable. Whether you are using Web Broker or WebSnap, the wizard that creates your Web server application includes this as an option when you first begin the application. This creates a Web server application that is also a COM server. The first time you run your application, it registers your COM server so that the Web Application Debugger can access it. Before you can run the Web Application Debugger, you will need to run `bin\serverinfo.exe` once to register the ServerInfo application.

Launching your application with the Web Application Debugger

Once you have developed your Web server application, you can run and debug it using the Web Application Debugger. You can set breakpoints in it just like any other executable. When you run your application, it displays the console window of the COM server that is your Web server application. Once you start your application and run the Web App Debugger, the ServerInfo page is displayed in your default browser, and you can select your application from a drop-down list. Once you have selected your application, click the **Go** button. This launches your application in the Web Application Debugger, which provides you with details on request and response messages that pass between your application and the Web Application Debugger.

Converting your application to another type of Web server application after debugging

When you have finished debugging your Web server application with the Web Application Debugger, you will need to convert it to another type that can be installed on a commercial Web server.

1.7 Developing Web Services with Win32 Applications

Web Services are self-contained modular applications that can be published and invoked over the Internet. Web Services provide well-defined interfaces that describe the services provided. Unlike Web server applications that generate Web pages for client browsers, Web Services are not designed for direct human interaction. Rather, they are accessed programmatically by client applications. This section gives an overview of web services and web services support.

Topics

Name	Description
Web Services Overview (see page 44)	Web Service applications are server implementations that do not require clients to use a specific platform or programming language. These applications define interfaces in a language-neutral document, and they allow multiple communication mechanisms. Web Services are designed to work using Simple Object Access Protocol (SOAP). SOAP is a standard lightweight protocol for exchanging information in a decentralized, distributed environment. SOAP uses XML to encode remote procedure calls and typically uses HTTP as a communications protocol. Web Service applications use a Web Service Definition Language (WSDL) document to publish information on interfaces that are available and how to call them. On... more (see page 44)

1.7.1 Web Services Overview

Web Service applications are server implementations that do not require clients to use a specific platform or programming language. These applications define interfaces in a language-neutral document, and they allow multiple communication mechanisms.

Web Services are designed to work using Simple Object Access Protocol (SOAP). SOAP is a standard lightweight protocol for exchanging information in a decentralized, distributed environment. SOAP uses XML to encode remote procedure calls and typically uses HTTP as a communications protocol.

Web Service applications use a Web Service Definition Language (WSDL) document to publish information on interfaces that are available and how to call them. On the server side, your application can publish a WSDL document that describes your Web Service. On the client side, a wizard or command-line utility can import a published WSDL document, providing you with the interface definitions and connection information you need. If you already have a WSDL document that describes the Web service you want to implement, you can generate the server-side code when you import the WSDL document.

Using Web Services (see page 2291)

1.8 Developing Windows Applications

Windows provides a traditional approach to developing user interfaces, client/server applications, controls, and application logic. This section provides an overview of Windows application development using RAD Studio for Win32 and outlines the steps you would use to build a simple Windows project.

Topics

Name	Description
Windows Overview (see page 45)	The Windows platform provides several ways to help you create and build applications. The most common types of Windows applications are: • GUI Applications • Console Applications • Service Applications • Packages and DLLs

1.8.1 Windows Overview

The Windows platform provides several ways to help you create and build applications. The most common types of Windows applications are:

- GUI Applications
- Console Applications
- Service Applications
- Packages and DLLs

GUI Applications

A graphical user interface (GUI) application is designed using graphical components such as windows, menus, dialog boxes, and other features that make the application easy to use. When you compile a GUI application, an executable file with start-up code is created from your source files. The executable usually provides the basic functionality of your program. Simple programs often consist of only an executable file. You can extend the application by calling DLLs, packages, and other support files from the executable.

The RAD Studio IDE offers two application UI models:

- Single Document Interface (SDI)
- Multiple Document Interface (MDI)

Single Document Interface

A SDI application normally contains a single document view.

Multiple Document Interface

In an MDI application, more than one document or child window can be opened within a single parent window. This is common in applications such as spreadsheets or word processors.

MDI applications require more planning and are more complex to design than SDI applications. MDI applications spawn child windows that reside within the client window; the main form contains child forms. For instance, you need to set the FormStyle property of the TForm object to specify whether a form is a child (fsMDIChild) or main form (fsMDIForm). It is a best practice to define a base class for your child forms and derive each child form from this class. Otherwise, you will have to reset the form properties of the child. MDI applications often include a Window pop-up on the main menu that has items such as Cascade and Tile for viewing multiple windows in various styles. When a child window is minimized, its icon is located in the MDI parent form.

Console Applications

Console applications are 32-bit programs that run in a console window without a graphical interface. These applications typically do not require much user input and perform a limited set of functions. Any application that contains `{$APPTYPE CONSOLE}` in the code opens a console window of its own.

Service Applications

Service applications take requests from client applications, process those requests, and return the information to the client applications. Service applications typically run in the background without much user input. A Web, FTP, or an email server is an example of a service application.

Creating Packages and DLLs

Dynamic link libraries (DLLs) are modules of compiled code that work in conjunction with an executable to provide functionality to an application. You can create DLLs in cross-platform programs.

Packages are special DLLs used by Delphi applications, the IDE, or both. The two types of packages are runtime and designtime. Runtime packages provide functionality to a program while that program is running. Designtime packages extend the functionality of the IDE.

For most applications, packages provide greater flexibility and are easier to create than DLLs. However,here are a few situations where DLLs would work better than packages:

- Your code module will be called from non-Delphi applications.
- You are extending the functionality of a Web server.
- You are creating a code module to be used by third-party developers.
- Your project is an OLE container.

You cannot pass Delphi runtime type information (RTTI) across DLLs or from a DLL to an executable. If you pass an object from one DLL to another DLL or to an executable, you will not be able to use the **is** or **as** operators with the passed object. This is because the **is** and **as** operators need to compare RTTI. If you need to pass objects from a library, use packages instead of DLLs, because packages can share RTTI. Similarly, you should use packages instead of DLLs in Web Services because they rely on Delphi RTTI.

2 Procedures

This section provides how-to information for various areas of RAD Studio development.

Topics

Name	Description
CodeGuard Procedures (see page 48)	Use these procedures to debug your C++ applications with CodeGuard.
Database Procedures (see page 50)	This topic describes how to use the database components in the **Tool Palette**, like **dbGo** components, **dbExpress** components, **BDE** components, and **DataSnap** components.
Interoperable Applications Procedures (see page 79)	Delphi provides wizards and classes to make it easy to implement applications based on the Component Object Model (COM) from Microsoft. The simplest COM objects are servers that expose properties and methods (and possibly events) through a default interface that clients can call. The **COM Object Wizard** builds a lightweight COM object whose default interface descends from IUnknown or that implements an interface already registered on your system. This wizard provides the most flexibility in the types of COM objects you can create.
Reporting Procedures (see page 81)	This topic provides how-to information on using reporting solutions.
VCL Procedures (see page 82)	This section provides how-to information on developing VCL for Win32 applications.
WebSnap Procedures (see page 147)	This section provides how-to information on developing WebSnap applications. Please note that WebSnap is being deprecated in RAD Studio. Although WebSnap is still documented in the online help, the WebSnap product is no longer fully supported. As an alternative, you should begin using IntraWeb (VCL for the Web). IntraWeb (see page 2254) is documented in this online help. For more documentation on VCL for the Web, go to http://www.atozed.com/intraweb/docs/.
Web Services Procedure (see page 153)	This section provides how-to information on developing and using web services.

2.1 CodeGuard Procedures

Use these procedures to debug your C++ applications with CodeGuard.

Topics

Name	Description
Using CodeGuard (see page 48)	This procedure describes how to use CodeGuard when debugging a C++ application.

2.1.1 Using CodeGuard

This procedure describes how to use CodeGuard when debugging a C++ application.

To run a C++ application with CodeGuard reporting

1. Enable the CodeGuard reporting tool.
2. Enable CodeGuard compiler options for your project.
3. Choose **Run** ▶ **Run** to run your application.

During the execution of your application, CodeGuard runtime errors appear in the **Message** view.

CodeGuard also generates an error log named `<project_name>.cgl` that lists any errors it finds. The error log is located in the same directory as your executable.

Note: If you suspect that your program accesses a freed memory block but CodeGuard does not report an error, increase the value of Maximum memory block size

or **Delay queue length** on the **Resource Options** page of the **Configure CodeGuard** dialog box.

To enable the CodeGuard reporting tool

1. Choose **Tools** ▶ **CodeGuard Configuration** to display the **CodeGuard Configuration** dialog box.
2. Verify that CodeGuard is enabled.
3. Click **OK**.

Note: If you change any CodeGuard settings in the CodeGuard Configuration

dialog box, CodeGuard generates a `.cgi` configuration file with the same name and directory as your project file.

To enable CodeGuard compiler options for your project

1. Choose **Project** ▶ **Options** ▶ **C++ Compiler** ▶ **Debugging** to display the CodeGuard compiler options.
2. Check **Enable all CodeGuard options** to enable full CodeGuard coverage.
3. Click **OK**.
4. Rebuild your project.

Note: If you compile and link your project in separate steps, remember to include the CodeGuard library (cg32.lib

) before including other libraries.

See Also

CodeGuard Overview (see page 9)

CodeGuard Configuration dialog box

2.2 Database Procedures

This topic describes how to use the database components in the **Tool Palette**, like **dbGo** components, **dbExpress** components, **BDE** components, and **DataSnap** components.

Topics

Name	Description
Accessing Schema Information (see page 51)	The schema information or metadata includes information about what tables and stored procedures are available on the server and the information about these tables and stored procedures (like the fields of a table, the indexes that are defined, and the parameters a stored procedure uses).
Using Data Explorer to Obtain Connection Information (see page 52)	Before you have a connection, you can use **Data Explorer** to assemble connection strings.
Configuring TSQL Connection (see page 53)	The first step when working with a unidirectional dataset is to connect it to a database server. At designtime, once a dataset has an active connection to a database server, the **Object Inspector** can provide drop-down lists of values for other properties. For example, when representing a stored procedure, you must have an active connection before the **Object Inspector** can list what stored procedures are available on the server. The connection to a database server is represented by a separate **TSQLConnection** component. You work with **TSQLConnection** like any other database connection component.
Connecting to the Application Server using DataSnap Components (see page 55)	A client application uses one or more connection components in the **DataSnap** category of the **Tool Palette** to establish and maintain a connection to an application server.
Debugging dbExpress Applications using TSQLMonitor (see page 55)	While you are debugging your database application, you can monitor the SQL messages that are sent to and from the database server through your connection component, including those that are generated automatically for you (for example by a provider component or by the dbExpress driver).
Executing the Commands using TSQLDataSet (see page 56)	You can use a unidirectional dataset even if the query or stored procedure it represents does not return any records. Such commands include statements that use Data Definition Language (DDL) or Data Manipulation Language (DML) statements other than SELECT statements. The language used in commands is server-specific, but usually compliant with the SQL-92 standard for the SQL language. The SQL command you execute must be acceptable to the server you are using. Unidirectional datasets neither evaluate the SQL nor execute it, but pass the command to the server for execution.
Fetching the Data using TSQLDataSet (see page 57)	
Specifying the Data to Display using TSQLDataSet (see page 58)	
Specifying the Provider using TLocalConnection or TConnectionBroker (see page 59)	Client datasets are specialized datasets that hold all the data in memory. They use a provider to supply them with data and apply updates when they cache updates from a database server or another dataset, represent the data in an XML document, and store the data in the client portion of a multi-tiered application.
Using BDE (see page 60)	
Using DataSnap (see page 60)	A multi-tiered client/server application is partitioned into logical units, called tiers, which run in conjunction on separate machines. Multi-tiered applications share data and communicate with one another over a local-area network or even over the Internet. They provide many benefits, such as centralized business logic and thin client applications. Multi-tiered applications use the components on the **DataSnap** category in the **Tool Palette**. DataSnap provides multi-tier database capability to Delphi applications by allowing client applications to connect to providers in an application server.
Using TBatchMove (BDE) (see page 61)	**TBatchMove** copies a table structure or its data. It can be used to move entire tables from one database format to another.

Connecting to Databases with TDatabase (see page 62)	**TDatabase** sets up a persistent connection to a database, especially a remote database requiring a user login and password. **TDatabase** is especially important because it permits control over database transaction processing with the BDE when connected to a remote SQL database server. Use **TDatabase** when a BDE-based database application requires: • Persistent database connections • Customized database server logins • Transaction control • Application-specific BDE aliases
Using TQuery (Procedure) (see page 63)	**TQuery** is a query-type dataset that encapsulates an SQL statement and enables applications to access the resulting records.
Using TSQLQuery (see page 65)	**TSQLQuery** represents a query that is executed using dbExpress. **TSQLQuery** can represent the results of a SELECT statement or perform actions on the database server using statements such as INSERT, DELETE, UPDATE, ALTER TABLE, and so on. You can add a **TSQLQuery** component to a form at design time, or create one dynamically at runtime.
Using TSQLStoredProc (Procedure) (see page 66)	**TSQLStoredProc** represents a stored procedure that is executed using dbExpress. **TSQLStoredProc** can represent the result set if the stored procedure returns a cursor. You can add a **TSQLStoredProc** component to a form at design time, or create one dynamically at runtime.
Using TSQLTable (see page 66)	**TSQLTable** represents a database table that is accessed using dbExpress. **TSQLTable** generates a query to fetch all of the rows and columns in a table you specify. You can add a **TSQLTable** component to a form at designtime, or create one dynamically at runtime.
Managing Database Sessions Using TSession (see page 67)	A session provides global connection over a group of database components. A default **TSession** component is automatically created for each database application. You must use **TSession** component only if you are creating a multithreaded database application. Each database thread requires its own session components.
Using TSimpleDataSet (see page 68)	**TSimpleDataSet** is a special type of client dataset designed for simple two-tiered applications. Like a unidirectional dataset, it can use an SQL connection component to connect to a database server and specify an SQL statement to execute on that server. Like other client datasets, it buffers data in memory to allow full navigation and editing support.
Using TSimpleObjectBroker (see page 69)	If you have multiple COM-based servers that your client application can choose from, you can use an Object Broker to locate an available server system.
Using TStoredProc (see page 69)	TStoredProc is a stored procedure-type dataset that executes a stored procedure that is defined on a database server.
Using TTable (Procedure) (see page 70)	TTable is a table-type dataset that represents all of the rows and columns of a single database table.
Using TUpdateSQL to Update a Dataset (see page 72)	When the BDE-enabled dataset represents a stored procedure or a query that is not “live”, it is not possible to apply updates directly from the dataset. Such datasets may also cause a problem when you use a client dataset to cache updates.
Using dbExpress (see page 72)	
Adding a New Connection to the Data Explorer (see page 73)	You can add new connections to the **Data Explorer**, which persist as long as the connection object exists.
Browsing a Database in the Data Explorer (see page 74)	Once you have a live connection, you can use the **Data Explorer** to browse database objects.
Executing SQL in the Data Explorer (see page 74)	You can write, edit, and execute SQL in an **SQL Window**, which is available from within the **Data Explorer**.
Modifying Connections in the Data Explorer (see page 75)	You can modify connections in a variety of ways from the **Data Explorer**.
Connecting to a Database using the dbExpress Driver Framework (see page 76)	This procedure tells how to use the dbExpress driver framework to connect to a database and read its records. In the sample code, the dbExpress ini files contain all the information about the particular database connection, such as driver, user name, password, and so on.

2.2.1 Accessing Schema Information

The schema information or metadata includes information about what tables and stored procedures are available on the server

and the information about these tables and stored procedures (like the fields of a table, the indexes that are defined, and the parameters a stored procedure uses).

To access schema information

1. To populate a unidirectional dataset with metadata from the database server, call SetSchemaInfo method to indicate what data you want to see.
2. Set the type of schema information parameter of SetSchemaInfo method.
3. Set the name of table or stored procedure parameter of SetSchemaInfo method.
4. To fetch data after using the dataset for metadata, do one of the following:

- Set the CommandText property to specify the query, table, or stored procedure from which you want to fetch data.
- Set the type of schema information to stNoSchema and call SetSchemaInfo method.

  Note: If you choose the second option, the dataset fetches the data specified by the CommandText property.

Using Unidirectional Datasets (see page 1823)

2.2.2 Using Data Explorer to Obtain Connection Information

Before you have a connection, you can use **Data Explorer** to assemble connection strings.

To browse database providers

1. Choose **View** ▶ **Data Explorer** or click the **Data Explorer** tab in the **Project Manager**.
2. Expand a provider node under **dbExpress** to expose the list of available database providers.
3. Expand the second–level provider node to view the list of potential connections.

To get connection information

1. In the **Data Explorer** list of providers, right-click a second–level provider.
2. In the context menu, click Modify Connection. The **Modify Connection** dialog is displayed.
3. In the **Modify Connection** dialog, click **Advanced**. The **Advanced Properties** dialog is displayed, containing a scrollable list

of connection properties. The left column contains connection string keys; the right column contains their values.

To format a connection string

1. In the **Advanced Properties** dialog, enter values in the right-hand column for the connection properties named in the left column.
2. The text field at the bottom of the **Advanced Properties** dialog contains the resulting connection string text. Drag the cursor over the connection string text to select the connection string text. Copy the text. You can then paste this connection string wherever you want.

Adding a New Connection (see page 73)

Modifying Connections (see page 75)

2.2.3 Configuring TSQL Connection

The first step when working with a unidirectional dataset is to connect it to a database server. At designtime, once a dataset has an active connection to a database server, the **Object Inspector** can provide drop-down lists of values for other properties. For example, when representing a stored procedure, you must have an active connection before the **Object Inspector** can list what stored procedures are available on the server. The connection to a database server is represented by a separate **TSQLConnection** component. You work with **TSQLConnection** like any other database connection component.

Metaprocedure: Configuring a TSQL Connection

1. Choose **File** ▸ **New** ▸ **Other**. The **New Items** dialog appears.
2. In the **New Items** dialog, select **Delphi Projects** and double-click **VCL Forms Application**. The **Windows Designer** displays.
3. From the **dbExpress** category of the **Tool Palette**, drag a **TSQLConnection** component to the form.
4. Identify the driver (see steps below).
5. Specify connection parameters (see steps below).
6. Identify a database connection (see steps below).
7. Display and use the **dbExpress Connection Editor** (see steps below).

To identify the driver

1. Select the **TSQLConnection** component.
2. In the **Object Inspector**, set the DriverName property, to an installed dbExpress driver.
3. Identify the files associated with the driver name. Select any of the following:

- The dbExpress driver
- The dynamic link library

Note: The relationship between the dbExpress driver or dynamic link library and the database name is stored in a file called dbxdrivers.ini

, which is updated when you install a dbExpress driver. The SQL connection component looks the dbExpress driver and the dynamic-link library up in `dbxdrivers.ini` when given the value of DriverName. When you set the DriverName property, **TSQLConnection** automatically sets the LibraryName and VendorLib properties to the names of the associated dlls. Once LibraryName and VendorLib have been set, your application does not need to rely on `dbxdrivers.ini`.

To specify a connection parameter

1. Double-click on the Params property in the **Object Inspector** to edit the parameters using **Value List Editor** at designtime.
2. Use the Params.Values property to assign values to individual parameters at run time.

To identify a database connection

1. Set the ConnectionName property to a valid connection name. This automatically sets the DriverName and Params properties.
2. Edit the Params property to change the saved set of parameter values.
3. Set the LoadParamsOnConnect property to **True** to develop your application using one database and deploy it using another. This causes **TSQLConnection** to automatically set DriverName and Params to the values associated with ConnectionName in `dbxconnections.ini` when the connection is opened.
4. Call the LoadParamsFromIniFile method. This method sets DriverName and Params to the values associated with ConnectionName in `dbxconnections.ini` (or in another file that you specify). You might choose to use this method if you want to then override certain parameter values before opening the connection.

To display the Connection Editor

1. Double-click the **TSQLConnection** component. The **dbExpress Connection Editor** appears, with a drop-down drivers list, a list of connection names for the currently selected driver, and a connection parameters table for the currently selected connection name.
2. From the **Driver Name** drop-down list, select a **driver** to indicate the connection to use.
3. From the **Connection Name** list, select a **connection name**.
4. Choose the configuration that you want.
5. Click the **Test Connection** button to check for a valid configuration.

To define and modify connections using the Connection Editor

1. To edit the currently selected named connections in `dbxconnections.ini`, edit the parameter values in the parameter table.
2. Click **OK**. The new parameter values are saved to `dbxconnections.ini`.
3. Click the **Add Connection** button to define a new connection. The **New Connection** dialog appears.
4. In the **New Connection** dialog box, set the **Driver Name** and the **Connection Name**.
5. Click **OK**.
6. Click the **Delete Connection** button to delete the currently selected named connection from `dbxconnections.ini`.
7. Click the **Rename Connection** button to change the name of the currently selected named connection.

2.2.4 Connecting to the Application Server using DataSnap Components

A client application uses one or more connection components in the **DataSnap** category of the **Tool Palette** to establish and maintain a connection to an application server.

To connect to the application server using DataSnap components

1. Identify the protocol for communicating with the application server.
2. Locate the server machine.
3. Identify the application server on the server machine.
4. If you are not using SOAP, identify the server using the ServerName or ServerGUID property.
5. Manage server connections.

See Also

Connecting to the Application Server (see page 1517)

Using TLocalConnection or TConnectionBroker (see page 59)

Using TSimpleObjectBroker (see page 69)

2.2.5 Debugging dbExpress Applications using TSQLMonitor

While you are debugging your database application, you can monitor the SQL messages that are sent to and from the database server through your connection component, including those that are generated automatically for you (for example by a provider component or by the dbExpress driver).

To debug dbExpress applications

1. Choose **File** ▶ **New** ▶ **Other**. The **New Items** dialog appears.
2. In the **New Items** dialog, select **Delphi Projects** and double-click **VCL Forms Application**. The **Windows Designer** displays.
3. To monitor SQL commands, from the **dbExpress** category of the **Tool Palette**, drag a **TSQLMonitor** component to the form.
4. Set the SQLConnection property of the **TSQLMonitor** to the **TSQLConnection** component.
5. Set the Active property of the **TSQLMonitor** to **True**.

To use a callback to monitor SQL commands

1. Use the SetTraceEvent method of the **TSQLConnection** component.
2. Set the TDBXTraceEvent event parameter.

The dbExpress driver triggers the event every time the SQL connection component passes a command to the server or the

server returns an error message.

Warning: Do not call SetTraceEvent if the TSQLConnection

object has an associated **TSQLMonitor** component. **TSQLMonitor** uses the callback mechanism to work, and **TSQLConnection** can only support one callback at a time.

Configuring TSQLConnection (see page 53)

Specifying Display Data (see page 58)

Fetching the Data (see page 57)

Executing the Commands (see page 56)

Accessing Schema Information (see page 51)

Using Unidirectional Datasets (see page 1823)

2.2.6 Executing the Commands using TSQLDataSet

You can use a unidirectional dataset even if the query or stored procedure it represents does not return any records. Such commands include statements that use Data Definition Language (DDL) or Data Manipulation Language (DML) statements other than SELECT statements. The language used in commands is server-specific, but usually compliant with the SQL-92 standard for the SQL language. The SQL command you execute must be acceptable to the server you are using. Unidirectional datasets neither evaluate the SQL nor execute it, but pass the command to the server for execution.

To execute commands

1. Choose **File** ▸ **New** ▸ **Other**. The **New Items** dialog appears.
2. In the **New Items** dialog, select **Delphi Projects** and double-click **VCL Forms Application**. The **Windows Designer** displays.
3. From the **dbExpress** category of the **Tool Palette**, drag a **TSQLDataSet** component to the form.
4. Specify the command to execute.
5. Execute the command.
6. Create and modify server metadata.

To specify the command to execute

1. Set the CommandType and CommandText properties in the **Object Inspector** to specify the command for a **TSQLDataSet**.
2. Set the SQL property in the **Object Inspector** to specify the SQL statement to pass to the server for a **TSQLQuery** .
3. Set the StoredProcName property in the **Object Inspector** to specify the name of the stored procedure to execute for a **TSQLStoredProc** .

To execute the command

1. If the dataset is an instance of a **TSQLDataSet** or a **TSQLQuery**, call the ExecSQL method.
2. If the dataset is an instance of a **TSQLStoredProc**, call the ExecProc method.

   Tip: If you are executing the query or stored procedure multiple times, it is a good idea to set the Prepared property to **True**.

To create and modify server metadata

1. To create tables in a database, use the CREATE TABLE statement.
2. To create new indexes for those tables, use the CREATE INDEX statement.
3. To add various metadata objects, use CREATE DOMAIN, CREATE VIEW, CREATE SCHEMA, and CREATE PROCEDURE statements.
4. To delete any of the above metadata objects, use DROP TABLE, DROP VIEW, DROP DOMAIN, DROP SCHEMA, and DROP PROCEDURE.
5. To change the structure of a table, use the ALTER TABLE statement.

Using TSQLTable (see page 66)

Using TSQLStoredProc (see page 66)

Using TSQLQuery (see page 65)

Using Unidirectional Datasets (see page 1823)

2.2.7 Fetching the Data using TSQLDataSet

To fetch the data

1. Choose **File** ▶ **New** ▶ **Other**. The **New Items** dialog appears.
2. In the **New Items** dialog, select **Delphi Projects** and double-click **VCL Forms Application**. The **Windows Designer** displays.
3. From the **dbExpress** category of the **Tool Palette**, drag a **TSQLDataSet** component to the form.
4. To fetch the data for a unidirectional dataset, do one of the following:

- In the **Object Inspector**, set the Active property to **True**.
- Call the Open method at runtime.

   Tip: Use GetMetadata property to selectively fetch metadata on a database object. Set GetMetadata to False if you are fetching a dataset for read-only purposes.

5. Set its Prepared property to **True** to prepare the dataset explicitly.
6. Call the NextRecordSet method to fetch multiple sets of records.

   Note: NextRecordSet returns a newly created TCustomSQLDataSet component that provides access to the next set of records. That is, the first time you call NextRecordSet, it returns a dataset for the second set of records. Calling NextRecordSet returns a third dataset, and so on, until there are no more sets of records. When there are no additional datasets, NextRecordSet does not return anything.

Using TSQLStoredProc (see page 66)

Using TSQLQuery (see page 65)

Using Unidirectional Datasets (see page 1823)

2.2.8 Specifying the Data to Display using TSQLDataSet

To specify the data to display

1. Choose **File** ▸ **New** ▸ **Other**. The **New Items** dialog appears.
2. In the **New Items** dialog, select **Delphi Projects** and double-click **VCL Forms Application**. The **Windows Designer** displays.
3. From the **dbExpress** category of the **Tool Palette**, drag a **TSQLDataSet** component to the form.
4. For **TSQLDataSet**, specify the type of unidirectional dataset by CommandType property in the **Object Inspector**.
5. Specify whether information comes from results of query, a database table, or a stored procedure.

To display results from a query

1. Set the CommandType property to ctQuery for a **TSQLDataSet**.
2. For **TSQLQuery**, drag a **TSQLQuery** component from the **Tool Palette** to the form.
3. Set the SQL property to the query you want to assign.
4. Select **TSQLDataSet**.
5. Click the CommandText property. The **CommandText Editor** opens.
6. In the **CommandText Editor**, set the SQL property to the text of the query statement.

   Note: When you specify the query, it can include parameters, or variables, the values of which can be varied at design time or runtime. Parameters can replace data values that appear in the SQL statement. SQL defines queries such as UPDATE queries that perform actions on the server but do not return records.

To display records in a table

1. In the **Object Inspector**, set the CommandType property to ctTable. **TSQLDataSet** generates a query based on the values of two properties: CommandText that specifies the name of the database table that the **TSQLDataSet** object should represent and SortFieldNames that lists the names of any fields to use to sort the data, in the order of significance
2. Drag a **TSQLTable** component to the form.
3. In the **Object Inspector** , set the TableName property to the table you want.
4. Set the IndexName property to the name of an index defined on the server or set the IndexFieldNames property to a

semicolon-delimited list of field names to specify the order of fields in the dataset.

To display the results of a stored procedure

1. In the **Object Inspector**, set the CommandType property to ctStoredProc.
2. Specify the name of the stored procedure as the value of the CommandText property.
3. Set the StoredProcName property to the name of the stored procedure for **TSQLStoredProc**.

   Note: After you have identified a stored procedure, your application may need to enter values for any input parameters of the stored procedure or retrieve the values of output parameters after you execute the stored procedure.

2.2.9 Specifying the Provider using TLocalConnection or TConnectionBroker

Client datasets are specialized datasets that hold all the data in memory. They use a provider to supply them with data and apply updates when they cache updates from a database server or another dataset, represent the data in an XML document, and store the data in the client portion of a multi-tiered application.

To specify the provider

1. Choose **File** ▶ **New** ▶ **Other**. The **New Items** dialog appears.
2. In the **New Items** dialog, select **Delphi Projects** and double-click **VCL Forms Application**. The **Windows Designer** displays.
3. From the **DataSnap** category of the **Tool Palette**, drag a **TConnectionBroker** component to the form if the provider is on a remote application server.
4. In the **Object Inspector**, set the ConnectionBroker property of your client dataset to the **TConnectionBroker** component to the form.
5. From the **DataSnap** category of the **Tool Palette**, drag a **TLocalConnection** component to the form if the provider is in the same application as the client dataset.
6. Set the RemoteServer property of your client dataset to the **TLocalConnection** component to the form.

2.2.10 Using BDE

To use BDE

1. Choose **File** ▸ **New** ▸ **Other**. The **New Items** dialog box opens.
2. In the **New Items** dialog, select **Delphi Projects** and double-click **VCL Forms Application**. The **Windows Designer** displays.
3. From the **BDE** category of the **Tool Palette**, drag a **TTable** component to the form. This will encapsulate the full structure of data in an underlying database table.
4. From the **BDE** category of the **Tool Palette**, drag a **TQuery** component to the form. This will encapsulate an SQL statement and enables applications to access the resulting records.
5. From the **BDE** category of the **Tool Palette**, drag a **TStoredProc** component to the form. This will execute a stored procedure that is defined on a database server.
6. From the **BDE** category of the **Tool Palette**, drag a **TBatchMove** component to the form. This will copy a table structure or its data.
7. From the **BDE** category of the **Tool Palette**, drag a **TUpdateSQL** component to the form. This will provide a way to update the underlying datasets.

Using TUpdateSQL (see page 72)

2.2.11 Using DataSnap

A multi-tiered client/server application is partitioned into logical units, called tiers, which run in conjunction on separate machines. Multi-tiered applications share data and communicate with one another over a local-area network or even over the Internet. They provide many benefits, such as centralized business logic and thin client applications.

Multi-tiered applications use the components on the **DataSnap** category in the **Tool Palette**. DataSnap provides multi-tier database capability to Delphi applications by allowing client applications to connect to providers in an application server.

To build multi-tiered database applications using DataSnap

1. Choose **File** ▶ **New** ▶ **Other**. The **New Items** dialog appears.
2. In the **New Items** dialog, select **Delphi Projects** and double-click **VCL Forms Application**. The **Windows Designer** displays.
3. From the **DataSnap** category of the **Tool Palette**, drag a **TDCOMConnection** component to the form. This will establish a DCOM connection to a remote server in a multi-tiered database application.
4. From the **DataSnap** category of the **Tool Palette**, drag a **TSocketConnection** component to the form. This will establish a TCP/IP connection to a remote server in a multi-tiered database application.
5. From the **DataSnap** category of the **Tool Palette**, drag a **TSimpleObjectBroker** component to the form. This will locate a server for a connection component from a list of available application servers.
6. From the **DataSnap** category of the **Tool Palette**, drag a **TWebConnection** component to the form. This will establish an HTTP connection to a remote server in a multi-tiered database application.
7. From the **DataSnap** category of the **Tool Palette**, drag a **TConnectionBroker** component to the form. This will centralize all connections to the application server so that applications do not need major rewriting when changing the connection protocol.
8. From the **DataSnap** category of the **Tool Palette**, drag a **TSharedConnection** component to the form. This will connect to a child remote data module when the application server is built using multiple remote data modules.
9. From the **DataSnap** category of the **Tool Palette**, drag a **TLocalConnection** component to the form. This will provide access to IAppServer methods that would otherwise be unavailable, and make it easier to scale up to a multi-tiered application at a later time. It acts like a connection component for providers that reside in the same application.

Connecting To Application Server (see page 55)

Deploying Multi-tiered Database Applications (DataSnap) (see page 1952)

Using TLocalConnection or TConnectionBroker (see page 59)

Using TSimpleObjectBroker (see page 69)

2.2.12 Using TBatchMove (BDE)

TBatchMove copies a table structure or its data. It can be used to move entire tables from one database format to another.

To use TBatchMove

1. Choose **File** ▶ **New** ▶ **Other**. The **New Items** dialog appears.
2. In the **New Items** dialog, select **Delphi Projects** and double-click **VCL Forms Application**. The **Windows Designer** displays.
3. Create a batch move component.
4. Specify a batch move mode.
5. Map data types.
6. Execute a batch move.
7. Handle batch move errors.

See Also

Using TBatchMove (see page 1683)

Using TTable (see page 70)

Using TQuery (see page 63)

Using TStoredProc (see page 69)

Using Update Objects to Update a Dataset (see page 1692)

Using TSession (see page 67)

2.2.13 Connecting to Databases with TDatabase

TDatabase sets up a persistent connection to a database, especially a remote database requiring a user login and password. **TDatabase** is especially important because it permits control over database transaction processing with the BDE when connected to a remote SQL database server. Use **TDatabase** when a BDE-based database application requires:

- Persistent database connections
- Customized database server logins
- Transaction control
- Application-specific BDE aliases

To connect to databases with TDatabase

1. Choose **File** ▸ **New** ▸ **Other**. The **New Items** dialog appears.
2. In the **New Items** dialog, select **Delphi Projects** and double-click **VCL Forms Application**. The **Windows Designer** displays.
3. Associate a database component with a session.
4. Identify the database.
5. Open a connection using TDatabase.

To associate a database component with a session

1. From the **BDE** category of the **Tool Palette**, drag a **TDatabase** component to the form.
2. Drag a **TSession** component to the form.
3. In the **Object Inspector**, set the SessionName property of the **TSession** component. SessionName is set to “Default," which means it is associated with the default session component that is referenced by the global Session variable.
4. Add a **TSession** component for each session if you use multiple sessions.
5. Set the SessionName property of the **TDatabase** component to the SessionName property of the **TSession** component to associate your dataset with a session component.
6. Read the Session property to access the session component with which the database is associated at runtime. If SessionName is blank or “Default," the Session property references the same **TSession** instance referenced by the global Session variable.

Session enables applications to access the properties, methods, and events of a database component’s parent session component without knowing the session’s actual name. If you are using an implicit database component, the session for that database component is the one specified by the dataset’s SessionName property.

To identify the database

1. In the drop-down lists for dataset components, specify the alias name or the name of an existing BDE alias for a database component.

   Note: This clears any value already assigned to DriverName. Alternatively, you can specify a driver name instead of an alias when you create a local BDE alias for a database component using the DatabaseName property. Specifying the driver name

clears any value already assigned to AliasName. To provide your own name for a database connection, set the DatabaseName. To specify a BDE alias at designtime, assign a BDE driver.

2. Create a local BDE alias.
3. Double-click a database component. The **Database** editor opens.
4. In the **Name** edit box in the properties editor, enter the same name as specified by the DatabaseName property.
5. In the **Alias name** combo box, enter an existing BDE alias name or choose from existing aliases in the drop-down list.
6. To create or edit connection parameters at designtime, do one of the following:

- Use the Database Explorer or BDE Administration utility.
- Double-click the Params property in the **Object Inspector** to invoke the **Value List** editor.
- Double-click a database component in a data module or form to invoke the **Database** editor.

Note: All of these methods edit the Params property for the database component. When you first invoke the Database Properties

editor, the parameters for the BDE alias are not visible. To see the current settings, click **Defaults**. The current parameters are displayed in the Parameter overrides memo box. You can edit existing entries or add new ones. To clear existing parameters, click **Clear**. Changes you make take effect only when you click **OK**.

To open a connection using TDatabase

1. In the Params property of a **TDatabase** component, configure the ODBC driver for your application.
2. To connect to a database using **TDatabase**, set the Connected property to **True** or call the Open method.

Note: Calling TDatabase. Rollback does not call TDataSet. Cancel for any data sets associated with the database.

Using TStoredProc (see page 69)

Using TBatchMove (see page 61)

Using TUpdateSQL (see page 72)

2.2.14 Using TQuery (Procedure)

TQuery is a query-type dataset that encapsulates an SQL statement and enables applications to access the resulting records.

To use TQuery

1. Choose **File** ▶ **New** ▶ **Other**. The **New Items** dialog appears.
2. In the **New Items** dialog, select **Delphi Projects** and double-click **VCL Forms Application**. The **Windows Designer** displays.
3. Associate the dataset with database and session connections.
4. Create heterogeneous queries.

5. Obtain an editable result set.
6. Update read-only result sets.

To associate a dataset with database and session connections

1. From the **BDE** category of the **Tool Palette**, drag a **TDatabase** component to the form.
2. Drag a **TSession** component to the form.
3. Set the DatabaseName property of the **TDatabase** component to associate a BDE-enabled dataset with a database. For the **TDatabase** component, database name is the value of the DatabaseName property of the database component.
4. Specify a BDE alias as the value of DatabaseName if you want to use an implicit database component and the database has a BDE alias.

   Note: A BDE alias represents a database plus configuration information for that database. The configuration information associated with an alias differs by database type (Oracle, Sybase, InterBase, Paradox, dBASE, and so on).

5. In the **Object Inspector**, set the DatabaseName to specify the directory where the database tables are located if you want to use an implicit database component for a Paradox or dBASE database.
6. Use the default session to control all database connections in your application.
7. Set the SessionName property of the **TSession** component to associate your dataset with an explicitly created session component .

   Note: Whether you use the default session or explicitly specify a session using the SessionName property, you can access the session associated with a dataset by reading the DBSession property. If you use a session component, the SessionName property of a dataset must match the SessionName property for the database component with which the dataset is associated.

To create mixed queries

1. Define separate BDE aliases for each database accessed in the query using the BDE Administration tool or the SQL explorer.
2. Leave the DatabaseName property of the **TQuery** component blank. The names of the databases used will be specified in the SQL statement.
3. Set the SQL property to the SQL statement you want to execute.
4. Precede each table name in the statement with the BDE alias for the database of the table, enclosed in colons. This whole reference is then enclosed in quotation marks.
5. Set the Params property to any parameters for the query.
6. Write a Prepare method to prepare the query for execution prior to executing it for the first time.
7. Write an Open or ExecSQL method depending on the type of query you are executing.
8. Use a **TDatabase** component as an alternative to using a BDE alias to specify the database in a mixed query.
9. Configure the **TDatabase** to the database, set the TDatabase. DatabaseName to an unique value, and use that value in the SQL statement instead of a BDE alias name.

To obtain an editable result set

1. Set RequestLive property of the **TQuery** component to **True**.
2. If the query contains linked fields, treat the result set as a read-only result set, and update it.

If an application requests a live result set, but the SELECT statement syntax does not allow it, the BDE returns either a read-only result set for queries made against Paradox or dBASE, or an error code for SQL queries made against a remote server.

To update read-only result sets

1. If all updates are applied to a single database table, indicate the underlying table to update in an OnGetTableName event handler.

2. Set the query's UpdateObject property to the **TUpdateSQL** object you are using to have more control over applying updates.
3. Set the DeleteSQL, InsertSQL, and ModifySQL properties of the update object to the SQL statements that perform the appropriate updates for your query's data.

If you are using the BDE to cache updates, you must use an update object.

Using TUpdateSQL (see page 72)

2.2.15 Using TSQLQuery

TSQLQuery represents a query that is executed using dbExpress. **TSQLQuery** can represent the results of a SELECT statement or perform actions on the database server using statements such as INSERT, DELETE, UPDATE, ALTER TABLE, and so on. You can add a **TSQLQuery** component to a form at design time, or create one dynamically at runtime.

To use TSQLQuery

1. From the **dbExpress** category of the **Tool Palette**, drag a **TSQLQuery** component to the form.
2. In the **Object Inspector**, set its Name property to a unique value appropriate to your application.
3. Set the SQLConnection property.
4. Click the ellipsis button next to the SQL property of the **TSQLQuery** component. The **String List** editor opens.
5. In the **String List** editor, type the query statement you want to execute.
6. If the query data is to be used with visual data controls, add a data source component to the form.
7. Set the DataSet property of the data source component to the query-type dataset.
8. To activate the query component, set the Active property to **True** or call the Open method at runtime.

2.2.16 Using TSQLStoredProc (Procedure)

TSQLStoredProc represents a stored procedure that is executed using dbExpress. **TSQLStoredProc** can represent the result set if the stored procedure returns a cursor. You can add a **TSQLStoredProc** component to a form at design time, or create one dynamically at runtime.

To use TSQLStoredProc

1. From the **dbExpress** category of the **Tool Palette**, drag a **TSQLStoredProc** component to the form.
2. In the **Object Inspector**, set its Name property to a unique value appropriate to your application.
3. Set the SQLConnection property.
4. Set the StoredProcName property to specify the stored procedure to execute.
5. If the stored procedure returns a cursor to be used with visual data controls, add a data source component to the form.
6. Set the DataSet property of the data source component to the stored procedure-type dataset.
7. Provide input parameter values for the stored procedure, if necessary.
8. To execute the stored procedure that returns a cursor, use the Active property or call the Open method.
9. Process any results.

2.2.17 Using TSQLTable

TSQLTable represents a database table that is accessed using dbExpress. **TSQLTable** generates a query to fetch all of the rows and columns in a table you specify. You can add a **TSQLTable** component to a form at designtime, or create one dynamically at runtime.

To use TSQLTable

1. Choose **File** ▶ **New** ▶ **Other**. The **New Items** dialog displays.

2. In the **New Items** dialog, select **Delphi Projects** and double-click **VCL Forms Application**. The **Windows Designer** displays.
3. From the **dbExpress** category of the **Tool Palette**, drag a **TSQLTable** component to the form.
4. In the **Object Inspector**, set its Name property to a unique value appropriate to your application.
5. Set the SQLConnection property
6. Set the TableName property to the name of the table in the database.
7. Add a data source component to the form.
8. Set the DataSet property of the data source component to the the name of the dataset.

Using TSimpleDataSet (see page 68)

Using Unidirectional Datasets (see page 1823)

2.2.18 Managing Database Sessions Using TSession

A session provides global connection over a group of database components. A default **TSession** component is automatically created for each database application. You must use **TSession** component only if you are creating a multithreaded database application. Each database thread requires its own session components.

To manage database sessions

1. Choose **File** ▸ **New** ▸ **Other**. The **New Items** dialog appears.
2. In the **New Items** dialog, select **Delphi Projects** and double-click **VCL Forms Application**. The **Windows Designer** displays.
3. Activate a session.
4. Specify default database connection behavior.
5. Manage database connections.
6. Work with password-protected Paradox and dBASE tables.
7. Work with BDE aliases.
8. Retrieve information about a session.
9. Create, Name, and Manage additional sessions.

See Also

Managing Database Sessions (see page 1664)

Using TTable (see page 70)

Using TQuery (see page 63)

Using TStoredProc (see page 69)

Using TDatabase (see page 62)

Using TBatchMove (see page 61)

Using TUpdateSQL (see page 72)

2.2.19 Using TSimpleDataSet

TSimpleDataSet is a special type of client dataset designed for simple two-tiered applications. Like a unidirectional dataset, it can use an SQL connection component to connect to a database server and specify an SQL statement to execute on that server. Like other client datasets, it buffers data in memory to allow full navigation and editing support.

To use TSQLStoredProc

1. From the **dbExpress** category of the **Tool Palette**, drag a **TSimpleDataSet** component to the form.
2. Set its Name property to a unique value appropriate to your application.
3. From the **dbExpress** section of the **Tool Palette**, drag a **TSQLConnection** component on the form.
4. Select **TSimpleDataSet** component. Set the Connection property to **TSQLConnection** component.
5. To fetch data from the server, do any of the following:

- Set CommandType to ctQuery and set CommandText to an SQL statement you want to execute on the server.
- Set CommandType to ctStoredProc and set CommandText to the name of the stored procedure you want to execute.
- Set CommandType to ctTable and set CommandText to the name of the database tables whose records you want to use.

6. If the stored procedure returns a cursor to be used with visual data controls, add a data source component to the form.
7. Set the DataSet property of the data source component to the **TSimpleDataSet** object.
8. To activate the dataset, use the Active property or call the Open method.
9. If you executed a stored procedure, use the Params property to retrieve any output parameters.

Accessing Schema Information (see page 51)

Using TSQLTable (see page 66)

Using TSQLStoredProc (see page 66)

Using TSQLQuery (see page 65)

Using Unidirectional Datasets (see page 1823)

2.2.20 Using TSimpleObjectBroker

If you have multiple COM-based servers that your client application can choose from, you can use an Object Broker to locate an available server system.

To use TSimpleObjectBroker

1. Choose **File** ▶ **New** ▶ **Other**. The **New Items** dialog appears.
2. In the **New Items** dialog, select **Delphi Projects** and double-click **VCL Forms Application**. The **Windows Designer** displays.
3. From the **DataSnap** category of the **Tool Palette**, choose the connection component depending on the kind of connection you want.
4. From the **Tool Palette**, drag a **TSimpleObjectBroker** to the form.
5. In the **Object Inspector**, set the ObjectBroker property of the connection component that you chose in Step 3 to use this broker.

   Warning: Do not use the ObjectBroker property with SOAP connections.

See Also

Using DataSnap (see page 60)

Connecting To Application Server (see page 55)

Using TLocalConnection or TConnectionBroker (see page 59)

2.2.21 Using TStoredProc

TStoredProc is a stored procedure-type dataset that executes a stored procedure that is defined on a database server.

To use TStoredProc

1. Choose **File** ▶ **New** ▶ **Other**. The **New Items** dialog appears.
2. In the **New Items** dialog, select **Delphi Projects** and double-click **VCL Forms Application**. The **Windows Designer** displays.
3. Associate a dataset with database and session connections.
4. Bind the parameters.

To associate a dataset with database and session connections

1. From the **BDE** category of the **Tool Palette**, drag a **TDatabase** component to the form.
2. To associate a BDE-enabled dataset with a database, set the DatabaseName property. For **TDatabase** component, database name is the value of the DatabaseName property of the database component.
3. Drag a **TSession** component to the form.
4. To control all database connections in your application, use the default session.
5. In the **Object Inspector**, set the SessionName property of the **TSession** component to associate your dataset with an explicitly created session component.

   Note: If you use a session component, the SessionName property of a dataset must match the SessionName property for the

database component with which the dataset is associated.

To bind parameters

1. From the **BDE** category of the **Tool Palette**, drag a **TStoredProc** component to the form.
2. Set the ParamBindMode property to default **pbByName** to specify how parameters should be bound to the parameters on the server.
3. View the stored procedure source code of a server in the SQL Explorer if you want to set ParamBindMode to **pbByNumber**.
4. Determine the correct order and type of parameters.
5. Specify the correct parameter types in the correct order.

   Note: Some servers also support binding parameters by ordinal value, the order in which the parameters appear in the stored procedure. In this case the order in which you specify parameters in the parameter collection editor is significant. The first parameter you specify is matched to the first input parameter on the server, the second parameter is matched to the second input parameter on the server, and so on. If your server supports parameter binding by ordinal value, you can set ParamBindMode to pbByNumber

   .

BDE Overview (see page 15)

Using TTable (see page 70)

Using TQuery (see page 63)

Using TBatchMove (see page 61)

Using TUpdateSQL (see page 72)

2.2.22 Using TTable (Procedure)

TTable is a table-type dataset that represents all of the rows and columns of a single database table.

To use TTable

1. Choose **File** ▸ **New** ▸ **Other**. The **New Items** dialog appears.
2. In the **New Items** dialog, select **Delphi Projects** and double-click **VCL Forms Application**. The **Windows Designer** displays.
3. Associate the dataset with the database and session connections.
4. Specify the table type for local tables and control read/write access to local tables.
5. Specify a dBASE index file.
6. Rename local tables.
7. Import data from another table.

To associate a dataset with database and session connections

1. From the **BDE** category of the **Tool Palette**, drag a **TDatabase** component to the form.
2. Drag a **TSession** component to the form.
3. To associate a BDE-enabled dataset with a database, in the **Object Inspector**, set the DatabaseName property of the **TDatabase** component . For a **TDatabase** component, the database name is the value of the DatabaseName property of the database component.

4. Use the default session to control all database connections in your application.
5. Set the SessionName property of the **TSession** component to associate your dataset with an explicitly created session component.

If you use a session component, the SessionName property of a dataset must match the SessionName property for the database component with which the dataset is associated.

To specify the TableType and control read/write access

1. From the **BDE** category of the **Tool Palette**, drag a **TTable** component to the form.
2. In the **Object Inspector**, set the TableType property if an application accesses Paradox, dBASE, FoxPro, or comma-delimited ASCII text tables. BDE uses the TableType property to determine the table's type.
3. Set TableType to ttDefault if your local Paradox, dBASE, and ASCII text tables use the file extensions like, .DB, .DBF, and .TXT.
4. For other extensions, set TableType to ttParadox for Paradox, ttDBase for dBASE, ttFoxPro for FoxPro, and ttASCII for Comma-delimited ASCII text respectively.
5. Set the table component's Exclusive property to **True** before opening the table to gain sole read/write access.

   Note: If the table is already in use when you attempt to open it, exclusive access is not granted. You can attempt to set Exclusive on SQL tables, but some servers do not support exclusive table-level locking. Others may grant an exclusive lock, but permit other applications to read data from the table.

To specify a dBASE index file

1. Set the IndexFiles property to the name of the non-production index file or list the files with a .NDX extension.
2. Specify one index in the IndexName property to have it actively sorting the dataset.
3. At designtime, click the ellipsis button in the IndexFiles property. The **Index Files** editor opens.
4. To add a non-production index file or file with .NDX extension, click the **Add** button in the **Index Files** dialog and select the file from the **Open** dialog.

   Note: For each non-production index file or .NDX file, repeat Steps 3 and 4.

5. After adding all desired indexes, click the **OK** button in the **Index Files** editor.

   Note: To do steps 3-5 at runtime, access the IndexFiles property using properties and methods of string lists.

To rename local tables

1. To rename a Paradox or dBASE table at design time, right-click the table component. A drop-down context menu opens.
2. From the context menu, select **Rename Table**.
3. To rename a Paradox or dBASE table at runtime, call the table's RenameTable method.

To import data from another table

1. Use the BatchMove method of a table component to import data, copy, update, append records from another table into this table, or delete records from a table.
2. Set the name of the table from which to import data, and a mode specification that determines which import operation to perform.

2.2.23 Using TUpdateSQL to Update a Dataset

When the BDE-enabled dataset represents a stored procedure or a query that is not “live”, it is not possible to apply updates directly from the dataset. Such datasets may also cause a problem when you use a client dataset to cache updates.

To update a dataset using an update object

1. From the **Tool Palette**, add a **TUpdateSQL** component to the same form as the BDE-enabled dataset.
2. In the **Object Inspector**, set the UpdateObject property of the BDE-enabled dataset component’s to the **TUpdateSQL** component in the form.
3. Set the ModifySQL, InsertSQL, and DeleteSQL properties of the update object to specify the SQL statements needed to perform updates.
4. Close the dataset.
5. Set the dataset component’s CachedUpdates property to **True** or link the dataset to the client dataset using a dataset provider.
6. Reopen the dataset.
7. Create SQL statements for update components.
8. Use multiple update objects.
9. Execute the SQL statements.

Using TSession (see page 67)

2.2.24 Using dbExpress

To build a database applications using dbExpress

1. Connect to the database server and configure a TSQL connection.
2. Specify the data to display.
3. Fetch the data.
4. Execute the commands.

5. Access the schema information.
6. Debug dbExpress application using **TSQLMonitor**.
7. Use **TSQLTable** to represent a table on a database server that is accessed via **TSQLConnection**.
8. Use **TSQLQuery** to execute an SQL command on a database server that is accessed via **TSQLConnection**.
9. Use **TSQLStoredProc** to execute a stored procedure on a database server that is accessed via **TSQLConnection**.

2.2.25 Adding a New Connection to the Data Explorer

You can add new connections to the **Data Explorer**, which persist as long as the connection object exists.

To add a new connection

1. Choose **View** ▸ **Data Explorer**. This displays the **Data Explorer**.
2. Select a provider from the tree list.
3. Right-click to display a pop-up menu.
4. Choose **Add New Connection**. This displays the **Add New Connection** dialog.
5. Enter the name of the new connection.
6. Click **OK**.

To modify connection settings

1. Right-click your connection and scroll down to **modify a connection**. A **Modify Connection** dialog appears.
2. Enter your connection settings and click **OK**.

See Also

Browsing a Database (see page 74)

Executing SQL in the Data Explorer (see page 74)

Modifying Connections (see page 75)

2.2.26 Browsing a Database in the Data Explorer

Once you have a live connection, you can use the **Data Explorer** to browse database objects.

To browse database objects

1. Choose **View** ▸ **Data Explorer**.
2. Expand a provider node to expose the list of available connections.
3. Expand a connection node to view the list of database objects (tables, views, and procedures).

   Note: If you receive an error because your connection is not live, you should refresh your provider, and/or modify your connection.

To retrieve data from the database

1. Expand a connection in the **Data Explorer**.
2. Double-click a table name or view name to retrieve data. This operation returns a result set into a tabbed **Data Explorer** page in the **Code Editor**.

   Tip: You can also select a table in the Data Explorer

   and right-click to display a pop-up menu with a **Retrieve Data From Table** command.

To run a stored procedure

1. Choose **View** ▸ **Data Explorer**.
2. Expand a connection in the **Data Explorer** and locate a stored procedure.
3. Double-click the stored procedure to view its parameters. The parameters open in a separate page on the design surface.
4. Edit input parameters as necessary.
5. Click the Execute button in the top left corner of the page to execute the procedure. The result set appears in a datagrid.

   Tip: You can also select a procedure in the Data Explorer

   and right-click to display a pop-up menu with an **Execute** command.

See Also

Adding a New Connection (see page 73)

Executing SQL in the Data Explorer (see page 74)

Modifying Connections (see page 75)

2.2.27 Executing SQL in the Data Explorer

You can write, edit, and execute SQL in an **SQL Window**, which is available from within the **Data Explorer**.

To open a SQL Window

1. Choose **View** ▸ **Data Explorer**.
2. Select a connection.

3. Right-click the connection and choose **SQL Window**. This opens a tabbed **SQL Window** in the **Code Editor**.

To execute SQL

1. Enter a valid SQL statement or stored procedure name in the multi-line text box at the top of the **SQL Window**.
2. Click **Execute SQL**. If the SQL statement or stored procedure is valid, the result set appears in the bottom pane of the **SQL Window**.

   Note: The SQL statement or stored procedure must operate against the current connection and its target database. You cannot execute SQL against a database to which you are not connected.

3. Click **Clear All SQL** to clear the SQL statement or stored procedure from the multi-line text box.

See Also

Browsing a Database (see page 74)

Adding a New Connection (see page 73)

Modifying Connections (see page 75)

2.2.28 Modifying Connections in the Data Explorer

You can modify connections in a variety of ways from the **Data Explorer**.

To modify connections

1. Choose **View** ▶ **Data Explorer**.
2. Select a provider.
3. Right-click to display a pop-up menu to view your options.

To refresh a connection

1. Choose **View** ▶ **Data Explorer**.
2. Select a provider.
3. Right-click to display a pop-up menu.
4. Choose **Refresh**. This operation reinitializes all connections defined for the selected provider.

To delete a connection

1. Choose **View** ▶ **Data Explorer**.
2. Select a connection.
3. Right-click to display a pop-up menu.
4. Choose **Delete Connection**. This displays a confirmation message that asks if you want to delete the connection.
5. Click **OK**.

To modify a connection

1. Choose **View** ▶ **Data Explorer**.
2. Select a connection.
3. Right-click to display a pop-up menu.
4. Choose **Modify Connection**. This displays the **Connections Editor** dialog.

5. Make changes to the appropriate values in the editor.
6. Click **OK**.

To close a connection

1. Choose **View** ▸ **Data Explorer**.
2. Select a connection.
3. Right-click to display a pop-up menu.
4. Choose **Close Connection**. If the connection is open, this operation closes it.

   Note: If the Close Connection

   command is disabled in the menu, the connection is not open.

To rename a connection

1. Choose **View** ▸ **Data Explorer**.
2. Select a connection.
3. Right-click to display a pop-up menu.
4. Choose **Rename Connection**. This displays **Rename Connection** dialog.
5. Enter a new name.
6. Click **OK**. The **Data Explorer** displays the connection with its new name.

See Also

Browsing a Database (see page 74)

Executing SQL in the Data Explorer (see page 74)

Adding a New Connection (see page 73)

2.2.29 Connecting to a Database using the dbExpress Driver Framework

This procedure tells how to use the dbExpress driver framework to connect to a database and read its records. In the sample code, the dbExpress ini files contain all the information about the particular database connection, such as driver, user name, password, and so on.

To connect to a database and read its records

1. Configure the connections ini file with the information about the database you are connecting to. This includes setting the driver name, user name, password, and so on.
2. Obtain a TDBXConnectionFactory, which is returned by TDBXConnectionFactory.GetConnectionFactory.
3. Get a TDBXConnectionobject returned by TDBXConnectionFactory.GetConnection.
4. Open the database connection by calling TDBXConnection.Open on the TDBXConnection instance.
5. Get a TDBXCommandobject by calling TDBXConnection.CreateCommand on the TDBXConnection instance.
6. Set the TDBXCommand's Textproperty to the desired SQL command. Call TDBXCommand.Prepare on the TDBXCommand instance.
7. Execute the SQL query by calling TDBXCommand.ExecuteQuery, which returns a TDBXReader instance.
8. Read the first database record by calling TDBXReader.Next. Call this method to retrieve successive database records.

9. Get whatever information you want from the database. For instance, TDBXReader.GetColumnCount returns the number of database columns. The TDBXReader properties ValueTypeand Value contain the data type and value for a given column number in the current record.

```
// This sample connects to a database using the ini files.
// These files must be configured for the database.
// Once connected, the sample reads values and displays the
// ANSI values for the first 100 records in a listbox.

// Get a TDBXConnection using a TDBXConnectionFactory.
// ConnectionName = section in the connections ini file.
class function TForm1.BuildConnectionFromConnectionName(
 ConnectionName: WideString): TDBXConnection;
var
 ConnectionFactory: TDBXConnectionFactory;
 ConnectionProps: TDBXProperties;
begin
 ConnectionFactory := TDBXConnectionFactory.GetConnectionFactory;
 ConnectionProps := ConnectionFactory.GetConnectionProperties(ConnectionName);
 Result := ConnectionFactory.GetConnection(ConnectionProps,
   ConnectionProps.Values[TDBXPropertyNames.UserName],
ConnectionProps.Values[TDBXPropertyNames.Password] );
end;

procedure Connect;
var
 connection: TDBXConnection;
 command: TDBXCommand;
 reader:   TDBXReader;
 value: TDBXValue;
 valueType: TDBXValueType;
 colCountStr: string;
 i, j: Integer;
 numCols: integer;
 ListBox1: TListBox;

const
 sqlCommand = 'select * from employee';

begin
 // Open connection to DB.
 connection := BuildConnectionFromConnectionName('ConnectionName');
 connection.Open;

 // Get command
 command := connection.CreateCommand();
 command.Text := sqlCommand;

 // Execute query
 command.Prepare;
 reader := command.ExecuteQuery;

 // Get values from DB
 if reader.Next then
 begin
 numCols := reader.GetColumnCount;
   Str(numCols, colCountStr);
   ListBox1.Items.Add('Number of columns = ' + colCountStr);
   j := 1;
   repeat
     for i := 0 to reader.GetColumnCount - 1 do
     begin
       valueType := reader.ValueType[i];
       if valueType.DataType = TDBXDataTypes.AnsiStringType then
```

```
        begin
          value := reader.Value[i];
          ListBox1.Items.Add(valueType.Name + ' = ' +
            value.GetString);
        end
        else
          ListBox1.Items.Add(valueType.Name);
      end;
      Inc(j);
    until (j > 100) or not reader.Next;

    reader.Next;
  end;

  // Free resources
  command.Free;
end;
```

2.3 Interoperable Applications Procedures

Delphi provides wizards and classes to make it easy to implement applications based on the Component Object Model (COM) from Microsoft. The simplest COM objects are servers that expose properties and methods (and possibly events) through a default interface that clients can call. The **COM Object Wizard** builds a lightweight COM object whose default interface descends from IUnknown or that implements an interface already registered on your system. This wizard provides the most flexibility in the types of COM objects you can create.

Topics

Name	Description
Using COM Wizards (see page 79)	RAD Studio provides wizards that help you create COM projects and COM objects. These wizards are available for both Delphi and C++ projects. The following COM wizards are available in the list for **File ▶ New ▶ Other ▶ <personality> ▶ ActiveX**: • Active Form • Active Server Object • ActiveX Control • ActiveX Library • Automation Object • COM Object • COM+ Event Object • COM+ Subscription Object • Property Page • Transactional Object • Type Library Two other related wizards are available from the **File ▶ New ▶ Other ▶ <personality> ▶ Multitier** list: • Remote Data Module • Transactional Data Module

2.3.1 Using COM Wizards

RAD Studio provides wizards that help you create COM projects and COM objects. These wizards are available for both Delphi and C++ projects. The following COM wizards are available in the list for **File ▶ New ▶ Other ▶ <personality> ▶ ActiveX**:

- Active Form
- Active Server Object
- ActiveX Control
- ActiveX Library
- Automation Object
- COM Object

- COM+ Event Object
- COM+ Subscription Object
- Property Page
- Transactional Object
- Type Library

Two other related wizards are available from the **File** ▸ **New** ▸ **Other** ▸ **<personality>** ▸ **Multitier** list:

- Remote Data Module
- Transactional Data Module

To use a COM wizard

1. Choose **File** ▸ **New** ▸ **Other**. The **New Items** dialog box displays.
2. In the **Item Categories** tree, click the **ActiveX** folder beneath your chosen personality, either **C++Builder Projects** or **Delphi Projects**.
3. In the **ActiveX** folder, double-click **ActiveX Library**. This creates a Dynamic Link Library [DLL] project that you can use to host in-process ActiveX Objects.
4. Choose **File** ▸ **New** ▸ **Other** again.
5. Do either one of the following:

- To display the COM wizards, click the same **ActiveX** folder that you clicked in step 2.
- To display the multitier wizards, click the **Multitier** folder in your selected personality.

6. Double-click the wizard that you want to use.

   Note: To create a client application to interact with the server created by a COM wizard, use the Import Component wizard or the TLIBIMP utility.

   If your application implements more than one COM object, you should specify the same instancing for all of them.

2.4 Reporting Procedures

This topic provides how-to information on using reporting solutions.

Topics

Name	Description
Adding Rave Reports to RAD Studio (see page 81)	Rave Reports offers a powerful set of tools for building reports and including them in your applications. Rave Reports are installed in a `\RaveReports` subdirectory in your installation directory. To make the Rave Reports more easily accessible, add the command executable to your **Tools** menu.

2.4.1 Adding Rave Reports to RAD Studio

Rave Reports offers a powerful set of tools for building reports and including them in your applications. Rave Reports are installed in a `\RaveReports` subdirectory in your installation directory. To make the Rave Reports more easily accessible, add the command executable to your **Tools** menu.

To add a Rave Reports command to the Tools menu

1. Choose **Tools** ▸ **Configure Tools**. This displays the **Tool Options** dialog box.
2. Click **Add**. This displays the **Tool Properties** dialog box.
3. Type `Rave Reports` in the **Title** text box.
4. Click the **Browse** button.
5. Browse to the `\RaveReports` subdirectory in your RAD Studio installation directory.
6. Select the **Rave.exe** icon.
7. Click **OK**. This adds the path for the program and the working directory to the **Tool Properties** dialog box.
8. Click **OK**
9. Click **Close**. This adds the command to your **Tools** menu that will initiate a Rave Reports session. Refer to the Rave Reports online Help for information on how to build and integrate report objects.

2.5 VCL Procedures

This section provides how-to information on developing VCL for Win32 applications.

Topics

Name	Description
Building a Windows "Hello World" Console Application (see page 88)	This "Hello World" console application demonstrates the essential steps for creating a Windows application in Delphi or C++. The application uses Windows, a console window, an event, and will display a dialog in response to a user action.
Developing a Windows Application (see page 89)	The following procedure illustrates the essential steps for building a Windows application.
Building Application Menus (see page 90)	Menus provide an easy way for your users to execute logically grouped commands. You can add or delete menu items, or drag them to rearrange them during designtime. In addition to **TMainMenu** and **TPopupMenu** components, the **Tool Palette** also contains **TActionMainMenuBar**, **TActionManager**, and **TActionToolBar**.
Building a VCL Forms Application with Decision Support Components (see page 91)	Creating a form with tables and graphs of multidimensional data consists of the following major steps: 1. Create a VCL form. 2. Add a decision query and dataset. 3. Add a decision cube. 4. Add a decision source. 5. Optionally add a decision pivot. 6. Add one or more decision grids and graphs. 7. Set the active property of the decision query (or alternate dataset component) to True.
Building VCL Forms Applications With Graphics (see page 93)	Each of the procedures listed below builds a VCL Form application that uses graphics. Build one or more of the examples and then add other graphics features to these basic VCL Form applications. 1. Draw straight lines. 2. Draw rectangles and ellipses. 3. Draw a polygon. 4. Display a bitmap image. 5. Place a bitmap in a combo box.
Building a VCL Forms MDI Application Using a Wizard (see page 93)	The VCL Forms MDI application wizard automatically creates a project that includes the basic files for an MDI application. In addition to the Main source file, the wizard creates unit files for child and about box windows, along with the supporting forms files and resources.
Building a VCL Forms MDI Application Without Using a Wizard (see page 94)	
Building a VCL Forms SDI Application (see page 96)	
Creating a New VCL Component (see page 97)	You can use the **New VCL Component** wizard to create a new VCL component for your application. The wizard detects the personality of the product you are using and creates the appropriate type of component.

Building a VCL Forms ADO Database Application (see page 98)	The following procedure describes how to build an ADO database application. Building a VCL ADO application consists of the following major steps: 1. Set up the database connection. 2. Set up the dataset. 3. Set up the data provider, client dataset, and data source. 4. Connect a DataGrid to the connection components. 5. Run the application.
Building a VCL Forms Application (see page 99)	The following procedure illustrates the essential steps to building a VCL Forms application using RAD Studio.
Creating Actions in a VCL Forms Application (see page 100)	Using RAD Studio, the following procedure illustrates how to create actions using the ActionList tool. It sets up a simple application and describes how to create a file menu item with a file open action. Building the VCL application with ActionList actions consists of the following major steps: 1. Create a main window and add tools for creating a main menu and a File open action. 2. Add the File category to the main menu. 3. Add the File open action to the File category. 4. Build and run the application.
Building a VCL Forms "Hello World" Application (see page 101)	This procedure demonstrates how to construct a simple “Hello world” VCL Forms application using either Delphi or C++. Though simple, the Windows Forms "Hello world" application demonstrates the essential steps for creating a VCL Forms application. The application uses a VCL Form, a control, an event, and displays a dialog in response to a user action. Creating the "Hello world" application consists of the following steps: 1. Create a VCL Form with a button control. 2. Write the code to display "Hello world" when the button is clicked. 3. Run the application.
Using ActionManager to Create Actions in a VCL Forms Application (see page 102)	Using RAD Studio, the following procedure illustrates how to create actions using ActionManager. It sets up a simple user interface with a text area, as would be appropriate for a text editing application, and describes how to create a file menu item with a file open action. Building the VCL application with ActionManager actions consists of the following major steps: 1. Create a main window. 2. Add a File open action to the ActionManager. 3. Create the main menu. 4. Add the action to the menu. 5. Build and run the application.
Building a VCL Forms dbExpress Database Application (see page 103)	The following procedure describes how to build a dbExpress database application. Building a VCL Forms dbExpress application consists of the following major steps: 1. Set up the database connection. 2. Set up the unidirectional dataset. 3. Set up the data provider, client dataset, and data source. 4. Connect a DataGrid to the connection components. 5. Run the application.

Building an Application with XML Components (see page 104)	This example creates a VCL Forms application that uses an XMLDocument component to display contents in an XML file.
Copying Data From One Stream To Another (see page 106)	Creating this VCL application consists of the following steps: 1. Create a project directory containing a text file to copy. 2. Create a VCL Form with a button control. 3. Write the code to read the string and write it to a file. 4. Run the application.
Copying a Complete String List (VCL) (see page 107)	Copying a string list can have the effect of appending to or overwriting an existing string list. This VCL application appends to a string list. With a simple change, it can overwrite a string list. Creating this VCL application consists of the following steps: 1. Create a VCL Form with TButtons, TComboBox, and TMemo controls. 2. Write the code to create a string list to the Button1 OnClick handler. 3. Write the code to copy the string list to the Button2 OnClick handler. 4. Run the application.
Creating Strings (see page 109)	Creating this VCL application consists of the following steps: 1. Create a VCL Form with TButton and TComboBox controls. 2. Write the code to create strings to the TButton OnClick handler. 3. Run the application.
Creating a VCL Form Instance Using a Local Variable (see page 110)	A safe way to create a unique instance of a modal VCL form is to use a local variable in an event handler as a reference to a new instance. If you use a local variable, it doesn't matter whether the form is auto-created or not. The code in the event handler makes no reference to the global form variable. Using RAD Studio, the following procedure creates a modal form instance dynamically. It (optionally) removes the second form's invocation at startup. Building this VCL application consists of the following steps: 1. Create the project directory. 2. Create two forms for the project.... more (see page 110)
Deleting Strings (see page 112)	Creating this VCL application consists of the following steps: 1. Create a VCL Form with Buttons and ListBox controls. 2. Write the code to add strings to a list. 3. Write the code to delete a string from the list. 4. Run the application.
Displaying an Auto-Created VCL Form (see page 113)	Using RAD Studio, the following procedure creates a modal form at design time that is displayed later during program execution. Building this VCL application consists of the following steps: 1. Create the project directory. 2. Create two forms for the project. 3. Link the forms. 4. Create a control on the main form to display the modal form; then write the event handler. 5. Build and run the application.

Displaying a Bitmap Image in a VCL Forms Application (see page 114)	This procedure loads a bitmap image from a file and displays it to a VCL form. 1. Create a VCL form with a button control. 2. Provide a bitmap image. 3. Code the button's onClick event handler to load and display a bitmap image. 4. Build and run the application.
Displaying a Full View Bitmap Image in a VCL Forms Application (see page 116)	This procedure loads a bitmap image from a file and displays it in its entirety to a VCL form. The procedure uses the Height and Width properties of the Bitmap object to display a full view of the image. 1. Create a VCL form with a button control. 2. Provide a bitmap image. 3. Code the button's onClick event handler to load and display a bitmap image. 4. Build and run the application.
Drawing a Polygon in a VCL Forms Application (see page 117)	This procedure draws a polygon in a VCL form. 1. Create a VCL form. 2. Code the form's OnPaint event handler to draw a polygon. 3. Build and run the application.
Drawing Rectangles and Ellipses in a VCL Forms Application (see page 118)	This procedure draws a rectangle and ellipse in a VCL form. 1. Create a VCL form. 2. Code the form's OnPaint event handler to draw a rectangle and ellipse. 3. Build and run the application.
Drawing a Rounded Rectangle in a VCL Forms Application (see page 118)	This procedure draws a rounded rectangle in a VCL form. 1. Create a VCL form and code the form's OnPaint event handler. 2. Build and run the application.
Drawing Straight Lines In a VCL Forms Application (see page 119)	This procedure draws two diagonal straight lines on an image in a VCL form. 1. Create a VCL form. 2. Code the form's OnPaint event handler to draw the straight lines. 3. Build and run the application.
Dynamically Creating a VCL Modal Form (see page 120)	You may not want all your VCL application's forms in memory at once. To reduce the amount of memory required at load time, your application can create forms only when it needs to make them available for use. A dialog box, for example, needs to be in memory only during the time the user interacts with it. Using RAD Studio, the following procedure creates a modal form dynamically. The main difference between dynamically creating a form and displaying an auto-created VCL form is that you remove the second form's invocation at startup and write code to dynamically create the form.... more (see page 120)

Dynamically Creating a VCL Modeless Form (see page 121)	A modless form is a window that is displayed until it is either obscured by another window or until it is closed or minimuzed by the user. Using RAD Studio, the following procedure creates a modeless form dynamically. Building this VCL application consists of the following steps: 1. Create the project directory. 2. Create two forms for the project. 3. Remove the second form's invocation at startup. 4. Link the forms. 5. Create a control on the main form to create and display the modal form; then write the event handler. 6. Build and run the application.
Iterating Through Strings in a List (see page 123)	This VCL application first creates a list of strings. Then it iterates through the strings, changing all string characters to uppercase. It consists of the following steps: 1. Create a VCL Form with Buttons and TListBox controls. 2. Write the code to create a string list and add strings to it. 3. Write the code to iterate through the string list to process string characters. 4. Run the application.
Building a Multithreaded Application (see page 124)	These are the essential steps to building a VCL Forms multithreaded application with a thread object using RAD Studio.
Writing Cleanup Code (see page 125)	
Avoiding Simultaneous Thread Access to the Same Memory (see page 125)	Use these basic techniques to prevent other threads from accessing the same memory as your thread: 1. Lock objects. 2. Use critical sections. 3. Use a multi-read exclusive-write synchronizer
Defining the Thread Object (see page 126)	
Handling Exceptions (see page 129)	
Initializing a Thread (see page 130)	
Using the Main VCL Thread (see page 131)	Using the main VCL thread consists of the following basic steps: 1. Create a separate routine to handle Windows messages received by components in your application. 2. Call CheckSynchronize periodically. 3. Declare thread-local variables, as necessary, for exclusive use by your thread.
Waiting for Threads (see page 132)	The following are procedures that can be used to wait for threads. • Wait for a thread to finish executing. • Wait for a task to complete. • Check if another thread is waiting for your thread to terminate.
Writing the Thread Function (Procedure) (see page 134)	The Execute method is your thread function. You can think of it as a program that is launched by your application, except that it shares the same process space. Writing the thread function is a little trickier than writing a separate program, because you must make sure that you do not overwrite memory that is used by other processes in your application. On the other hand, because the thread shares the same process space with other threads, you can use the shared memory to communicate between threads.

Placing A Bitmap Image in a Control in a VCL Forms Application (see page 135)	This procedure adds a bitmap image to a combo box in a VCL forms application. 1. Create a VCL form. 2. Place components on the form. 3. Set component properties in the Object Inspector. 4. Write event handlers for the component's drawing action. 5. Build and run the application.
Reading a String and Writing It To a File (see page 136)	Creating this VCL application consists of the following steps: 1. Create a VCL Form with a button control. 2. Write the code to read the string and write it to a file. 3. Run the application.
Renaming Files (see page 137)	Creating this VCL application consists of the following steps: 1. Create a project directory containing a file to rename. 2. Create a VCL Form with button and label controls. 3. Write the code to rename the file. 4. Run the application.
Adding and Sorting Strings (see page 138)	Creating this VCL application consists of the following steps: 1. Create a VCL Form with Button, Label, and TListBox controls. 2. Write the code to add and sort strings. 3. Run the application.
Creating a VCL Forms ActiveX Button (see page 139)	Like a Delphi control, an ActiveX control generates program code when you place the component on a form or other logical container in the IDE. The main difference between an ActiveX control and a Delphi control is that an ActiveX control is language independent. You can create ActiveX controls for deployment to a variety of programming environments on Windows, not just Delphi or C++Builder. This procedure uses the VCL forms ActiveX wizard to create an ActiveX control. To test the control, you can install it on your machine as a VCL component in the IDE. To install the control, you... more (see page 139)
Creating a VCL Forms ActiveX Active Form (see page 140)	Like a Delphi control, an ActiveX control generates program code when you place the component on a form or other logical container in the IDE. The main difference between an ActiveX control and a Delphi control is that an ActiveX control is language independent. You can create ActiveX controls for deployment to a variety of programming environments on Windows, not just Delphi or C++Builder, for example. This procedure uses the VCL forms ActiveX Active Form wizard to create an Active Form containing two components. To test the control, you can deploy it to the Web. This procedure consists of the... more (see page 140)
Building a VCL Forms Web Browser Application (see page 142)	Creating the Web browser application consists of the following steps: 1. Create a VCL Form with a button control. 2. Add a TWebBrowser component to the form. 3. Add controls to enter a URL and launch the browser. 4. Write the code to launch the browser when a button is clicked. 5. Run the application.

Creating an Application that Uses Ribbon Controls (see page 143)	This procedure describes how to create an application that uses ribbon controls. The core ribbon functionality is derived from the TRibbon component. While the ribbon uses other components, none of the core components are registered on the tool palette. **Components:** 1. **TRibbon:** Main visual component that provides most functionality. 2. **TRibbonApplicationMenuBar:** Component that provides the functionality of the application menu. 3. **TRibbonQuickAccessToolbar:** Component that provides the functionality of the Quick Access Toolbar 4. **TRibbonPage:** Component that represents the page of the ribbon that is currently visible 5. **TRibbonGroup:** Component that all of the pages commands are displayed in. Commands must be placed in a group.... more (see page 143)
Adding Commands to the Ribbon (see page 144)	This topic follows in sequence the creation of a ribbon application using either the Ribbon Application Wizard or the manual steps described in Creating an Application that Uses Ribbon Controls (see page 143). This topic assumes that you are familiar with the TActionManager component and the components associated with its use. Numerous new properties have been added to help support the ribbon requirements. Many existing properties have no effect when modified on a command that is displayed on the ribbon. For instance: • Small buttons always display their glyph to the left of the caption. • Large buttons always display their glyph at... more (see page 144)

2.5.1 Building a Windows "Hello World" Console Application

This "Hello World" console application demonstrates the essential steps for creating a Windows application in Delphi or C++. The application uses Windows, a console window, an event, and will display a dialog in response to a user action.

To create the "Hello world" console application

1. Create a Windows console application.
2. Create the logic.
3. Run the application.

To create a Windows console application

1. Choose **File** ▶ **New** ▶ **Other...**. The **New Items** dialog box appears.
2. In the **New Items** dialog box, select either **Delphi Projects** or **C++Builder Projects** and then double-click **Console Application**.
3. For C++, in the **New Console Application** dialog box, make sure that **VCL Forms** and **Multi-threaded** are unchecked, and **Console application** is checked. Then click **OK**.

To associate code with the console window

1. In the code template that is displayed in the **Code Editor**: For Delphi, enter the following statements after the **try** keyword and before the **except** keyword:

```
WriteLn('Hello, World!');

  ReadLn;
```

For C++, enter the following after `#pragma hdrstop`:

```
#include <iostream>
```

2. For C++, enter the following code after the opening brace ({):

```
std::cout<<"Hello, World!"<<std::endl;
std::cin.ignore();
```

3. Save the application.

To run the "Hello World" application

1. Choose **Run** ▶ **Run**. The application compiles and displays a console window with your "Hello World" message.
2. Press the ENTER key. The console window closes when the program terminates.

Windows Overview (see page 45)

Building a Windows Application (see page 89)

Building Applications Menus (see page 90)

2.5.2 Developing a Windows Application

The following procedure illustrates the essential steps for building a Windows application.

To create a Windows project

1. Select **New** ▶ **VCL Forms Application — Delphi for Win32**. The **Windows Designer** displays.
2. If necessary, select **Design** view.
3. From the **Tool Palette**, drag components onto the designer to create the user interface.
4. Associate logic with the controls.

To associate code with a control

1. In the Designer, double-click the component to which you want to apply logic. The **Code Editor** appears, cursor in place between the reserved words **begin** and **end** in the event handler.
2. Code your application logic.
3. Save and compile the application.

See Also

Windows Overview (see page 45)

Building a Windows "Hello World" Application (see page 88)

Building Windows Application Menus (see page 90)

2.5.3 Building Application Menus

Menus provide an easy way for your users to execute logically grouped commands. You can add or delete menu items, or drag them to rearrange them during designtime. In addition to **TMainMenu** and **TPopupMenu** components, the **Tool Palette** also contains **TActionMainMenuBar**, **TActionManager**, and **TActionToolBar**.

To create application menus

1. Choose **File** ▸ **New** ▸ **Other**. The **New Items** dialog appears.
2. In the **New Items** dialog, select **VCL Forms Application.** The **Windows Designer** displays.
3. Build application menus.
4. Use the Menu Designer.
5. Create an event handler for each menu item.
6. Move menu items.
7. Add images to menu items.

To build application menus

1. From the **Standard** category of the **Tool Palette**, add **TMainMenu** or **TPopupMenu** component to your form. A visual representation of the menu appears on the designer.

   Note: A TMainMenu

   component creates a menu that is attached to the title bar of the form. A **TPopupMenu** component creates a menu that appears when the user right-clicks in the form.
2. To view the menu, if the form is visible, click the form. The menu appears in the form exactly as it will when you run the program.
3. To delete a menu item, select the menu item you want to delete. Press `Delete`.
4. To edit menu items, select the VCL form, select the menu item you want to edit, and edit its properties.
5. To make the menu item a separator bar, place the cursor on the menu where you want a separator to appear and enter a hyphen (-) for the caption or press the hyphen (-) key.
6. To specify a keyboard shortcut for a menu item, in the **Object Inspector**, set the ShortCut property.

To use the Menu Designer

1. Select a menu component on the form.
2. Double-click the menu component. The **Menu Designer** window opens.

   Note: You can also open the Menu Designer

   by clicking the ellipsis(...) button next to the Items property in the **Object Inspector**.
3. To name a menu component, in the **Object Inspector**, set the Caption property.

   Tip: Delphi derives the Name property from the caption, for e.g. if you give a menu item a Caption property value of File, Delphi assigns the menu item a Name property of File1. However, if you fill in the Name property before filling in the Caption property, Delphi leaves the Caption property blank until you type a value.
4. Right-click anywhere on the Menu Designer to use the **Menu Designer** context menu. A drop-down list opens. This is the **Menu Designer** context menu.
5. To insert a placeholder below or to the right of the cursor, choose **Insert** from the context menu.

6. To delete the selected menu item (and all its subitems, if any), click **Delete** from the context menu.
7. To switch among menus in a form, choose **Select Menu** from the context menu. The **Select Menu** dialog box appears. It lists all the menus associated with the form whose menu is currently open in the Menu designer.
8. From the list in the **Select Menu** dialog box, choose the menu you want to view or edit.

To create an event handler for a menu item

1. In the designer, double-click the menu item to which you wish to add an event handler. The **Code Designer** appears, cursor in place between event handler brackets.
2. Code your menu item logic.
3. Save and compile the application.

To move menu items

1. To move a menu item along the desired menu bar, drag the item until the arrow tip of the cursor points to the new location.
2. Release the mouse button.
3. To move a menu item into a menu list, drag the item until the arrow tip of the cursor points to the new menu.
4. Release the mouse button.

To add images to menu items

1. From the **Tool Palette**, drag a **TMainMenu** or **TPopupMenu** component to a form.
2. From the **Tool Palette**, drop a **TImageList** component to the form.
3. Double-click on the **TImageList** component. The **ImageList** editor opens.
4. Click **Add** to select the bitmap or bitmap group you want to use in the menu.
5. Select the bitmap that you want and click **OK**.
6. In the **Object Inspector**, set the **Images** property of the **TMainMenu** or **TPopupMenu** component to the image you selected in the **ImageList** editor.

Windows Overview (see page 45)

Building a Windows Application (see page 89)

2.5.4 Building a VCL Forms Application with Decision Support Components

Creating a form with tables and graphs of multidimensional data consists of the following major steps:

1. Create a VCL form.
2. Add a decision query and dataset.
3. Add a decision cube.
4. Add a decision source.
5. Optionally add a decision pivot.
6. Add one or more decision grids and graphs.
7. Set the active property of the decision query (or alternate dataset component) to True.

To create a VCL form

1. Choose **File** ▶ **New** ▶ **Other** ▶ **Delphi Projects** and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** displays.
2. If necessary, click Form1 to make it the active window.

To add a decision dataset

1. From the **Decision Cube** page on the **Tool Palette**, add a DecisionQuery component to the top of the form.

   Tip: Place non-visual components such as this one in the top left corner of the form to keep them out of the way of visual components you will be adding.

2. Right-click the DecisionQuery component, and select **Decision Query Editor...**. The **Decision Query Editor** displays.
3. On the **Dimensions/Summary** tab, select the BCDEMOS database from the **Database:** drop-down list.
4. From the **Table:** drop-down, select the parts.db table. The **List of Available Fields:** listbox displays the fields in the parts.db table.
5. Use CTRL+Click to select the PartNo, OnOrder, and Cost fields; then click the right-arrow button next to the **Dimensions:** listbox. PartNo, OnOrder, and Cost display in the listbox.
6. Select the OnOrder field; then click the right-arrow button next to the **Summaries:** listbox and select count from the pop-up that displays. COUNT(OnOrder) displays in the **Summaries:** listbox.
7. Select the Cost field in the **List of Available Fields:** listbox; then click the right-arrow button next to the **Summaries:** listbox and select sum from the pop-up that displays. SUM(Cost) displays in the **Summaries:** listbox.
8. Click **OK** to close the **Decision Query Editor**.

   Note: When you use the Decision Query Editor, the query is initially handled in ANSI-92 SQL syntax and then translated (if necessary) into the dialect used by the server. The Decision Query editor reads and displays only ANSI standard SQL. The dialect translation is automatically assigned to the TDecisionQuery's SQL property. To modify a query, edit the ANSI-92 version in the Decision Query rather than the SQL property.

To add a decision cube

1. From the **Decision Cube** page on the **Tool Palette**, add a decision cube component to the top left corner of the form.
2. In the **Object Inspector**, select DecisionQuery1 from the drop-down list next to the decision cube's DataSet property.

To add a decision source

1. From the **Decision Cube** page on the **Tool Palette**, add a decision source component to the top left corner of the form.
2. In the **Object Inspector**, select DecisionCube1 from the drop-down list next to the decision source's DecisionCube property.

To add a decision pivot

1. From the **Decision Cube** page on the **Tool Palette**, add an optional DecisionPivot component to the top of the form.

   Tip: The decision pivot displays in the final application window. Place it to the right of the nonvisual components.

2. In the **Object Inspector**, select DecisionSource1 from the drop-down list next to the decision pivot's DecisionSource property.

To create a decision grid

1. From the **Decision Cube** page on the **Tool Palette**, add a decision grid component to the form just beneath the decision pivot.
2. In the **Object Inspector**, select DecisionSource1 from the drop-down list next to the decision grid's DecisionSource property.

To create a decision graph

1. From the **Decision Cube** page on the **Tool Palette**, add a decision graph component to the form just beneath the decision grid.
2. In the **Object Inspector**, select DecisionSource1 from the drop-down list next to the decision graph's DecisionSource property.

To run the application

1. In the **Object Inspector**, select True from the Active property drop-down. The visual decision graph, grid, and pivot components display data.
2. Choose **Run** ▶ **Run** to run the application. The application runs and displays the decision support components.
3. Use the decision pivot to update, as desired, the data displayed in the grid and graph.

2.5.5 Building VCL Forms Applications With Graphics

Each of the procedures listed below builds a VCL Form application that uses graphics. Build one or more of the examples and then add other graphics features to these basic VCL Form applications.

1. Draw straight lines.
2. Draw rectangles and ellipses.
3. Draw a polygon.
4. Display a bitmap image.
5. Place a bitmap in a combo box.

Placing A Bitmap Image In a Combo Box of a VCL Application (see page 135)

2.5.6 Building a VCL Forms MDI Application Using a Wizard

The VCL Forms MDI application wizard automatically creates a project that includes the basic files for an MDI application. In addition to the Main source file, the wizard creates unit files for child and about box windows, along with the supporting forms files and resources.

To create a new MDI application using a wizard

1. Choose **File** ▶ **New** ▶ **Other** ▶ **Delphi Projects** and double-click the **MDI Application** icon. The **Browse to Folder** dialog box is displayed.

2. Navigate to the folder in which you want to store the files for the project.
3. Click **OK**.
4. Choose **Run** ▶ **Run** to compile and run the application.
5. Try commands that are automatically set up by the MDI Application wizard.

See Also

VCL Overview (see page 36)

2.5.7 Building a VCL Forms MDI Application Without Using a Wizard

The basic steps to create a new MDI application with a child window without using a wizard are

1. Create a main window form (MDI parent window).
2. Create a child window form.
3. Have the main window create the child window under user control.
4. Write the event handler code to close the child window.
5. Create the main menu and commands.
6. Add the event handlers for the commands.
7. Compile and run the application.

To create the main window form

1. Choose **File** ▶ **New** ▶ **Other** ▶ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** is displayed.
2. In the **Object Inspector**, set the FormStyle property to fsMDIForm.
3. Enter a more descriptive name such as `frMain` for the Name property.
4. Save the unit file with a more descriptive name, such as `uMain.pas` (Delphi) or `uMain.cpp` (C++).

To create a child window

1. Choose **File** ▶ **New** ▶ **Form**
2. In the **Object Inspector**, set the FormStyle property to fsMDIChild.
3. Enter a more descriptive name such as frChild for the Name property.
4. Save the unit file as `uChild.pas` (Delphi) or `uChild.cpp` (C++).

To have the main window create the child window

1. Choose **Project** ▶ **Options** ▶ **Forms**. The **Project Options** dialog box appears.
2. Select **frChild** from **Auto-create forms** list and click **[>]** to move it to the **Available forms** list and click **OK**.
3. Select the frMain form to activate it; then switch to the Code view.
4. For Delphi, scroll to the `uses` section and add `uChild` to the list. For C++, add `#include "uChild.h"` to `uMain.h`.
5. For Delphi, scroll to the `private` declarations section and enter this procedure declaration:

```
procedure CreateChildForm(const childName: string);
```

For C++, add the following function declaration to the **private:** declarations of `TfrMain`.

```
void __fastcall CreateChildForm( const AnsiString childName );
```

6. For Delphi, scroll to the `implementation` section, and enter the code below:

```
procedure TfrMain.CreateChildForm (const childName: string);
  var Child: TfrChild;
  begin
    Child := TfrChild.Create(Application);
    Child.Caption := childName;
  end;
```

For C++, add the following function definition to `uMain.cpp`:

```
void __fastcall TfrMain::CreateChildForm( const AnsiString childName )
{
        TfrChild *Child = new TfrChild( Application );
        Child->Caption = childName;
}
```

To write the event handler code to close the child window

1. If necessary, activate the frMain form; then select the **Events** tab in the **Object Inspector**.
2. Double-click the OnClose event. The **Code Editor** displays with the cursor in the `TfrMain.FormClose` (Delphi) or `TfrMain::FormClose` (C++) event handler block.
3. For Delphi, enter the following code:

```
Action := caFree;
```

For C++, enter the following code:

```
Action = caFree;
```

To create the main menu and commands

1. From the **Standard** page on the Tool Palette, place a TMainMenu component on the main form.
2. Double-click the TMainMenu component. The Menu designer (frMain.MainMenu1) displays with the first blank menu item highlighted.
3. In the **Object Inspector** on the **Properties** tab, enter mnFile for the Name property and &File for the Caption property; then press ENTER. In the Menu designer, File displays as the name of the first menu item.
4. In the Menu designer, select File. A blank command field displays in the File group. Select the blank command.
5. In the **Object Inspector**, enter mnNewChild for the Name property and &New child for the Caption property; then press ENTER. In the Menu designer, New child displays as the name of the first file command, and a blank command field displays just beneath New child.
6. Select the blank command.
7. In the **Object Inspector**, enter mnCloseAll for the Name property and &Close All for the Caption property; then press ENTER. In the Menu designer, Close All displays as the name of the second file command.

To add event handlers for the New child and Close All commands

1. If necessary, open the Menu designer and select New child.
2. In the **Object Inspector**, double-click the OnClick event on the **Events** tab. The **Code Editor** displays with the cursor in the `TfrMain.mnNewChildClick` (Delphi) or `TfrMain::mnNewChildClick` (C++) event handler block.
3. For Delphi, enter the following code:

```
CreateChildForm('Child '+IntToStr(MDIChildCount+1));
```

For C++, enter the following code:

```
CreateChildForm( “Child “ + IntToStr( MDIChildCount + 1 ) );
```

4. In the Menu designer, select Close All.

5. In the **Object Inspector**, double-click the OnClick event on the **Events** tab. The **Code Editor** displays with the cursor in the `TfrMain.mnCloseAllClick` (Delphi) or `TfrMain::mnCloseAllClick` (C++) event handler block.
6. For Delphi, enter the following code:

```
for i:=0 to MDIChildCount - 1 do
  MDIChildren[i].Close;
```

For C++, enter the following code:

```
for( int i = 0; i < MDIChildCount; i++ ) {
        MDIChildren[i]->Close();
}
```

7. For Delphi, declare the local variable `i`. The first two lines of the event handler code should appear as shown here when you are done:

```
procedure TfrMain.mnCloseAllClick(Sender: TObject);
  var i: integer;
```

Note: The event handler minimizes the child window in the main window. To close the child window, you must add an OnClose procedure to the child form (next).

To close the child window

1. Activate the child form.
2. In the **Object Inspector**, double-click the OnClose event on the **Events** tab. The **Code Editor** displays with the cursor in the `TfrChild.FormClose` (Delphi) or `TfrChild::FormClose` (C++) event handler block.
3. For Delphi, enter the following statement:

```
Action := caFree;
```

For C++, enter the following statement:

```
Action = caFree;
```

To compile and run the MDI application

1. Choose **Run** ▸ **Run**.
2. The application executes, displaying the File command.
3. Choose **File** ▸ **New child** one or more times. A child window displays with each New child command.
4. Choose **File** ▸ **Close All**. The child windows close.

VCL Overview (see page 36)

2.5.8 Building a VCL Forms SDI Application

To create a new SDI application

1. Choose **File** ▸ **New** ▸ **Other** ▸ **Delphi Projects** and double-click the **SDI Application** icon.
2. Pick a folder to save the files in and click **OK**.
3. Choose **Run** ▸ **Run** to compile and run the application.

See Also

VCL Overview (see page 36)

2.5.9 Creating a New VCL Component

You can use the **New VCL Component** wizard to create a new VCL component for your application. The wizard detects the personality of the product you are using and creates the appropriate type of component.

Metaprocedure: Creating a new VCL component

1. Specify an ancestor component on the **Ancestor Component** page.
2. Specify the class name and other properties on the **Component** page.
3. Choose from three methods for creating a unit:

- Create a unit, on the **Create unit** page
- Install the unit to an existing package, on the **Existing package** page
- Install the unit as a new package, on the **New Package** page

To specify an ancestor component

1. Create a new package for the new component by choosing **File** ▸ **New** ▸ **Other** ▸ **Delphi Projects** and double-clicking the **Package** icon. This step adds a new package to the **Project Manager** and enables the **Add unit to <my_new_package>** option on the **Create unit** page.
2. In the IDE, choose **Component** ▸ **New VCL Component**. This step displays the first page of the **New VCL Component** wizard (the **Ancestor Component** page) and loads the page with names of components, along with the unit that defines each component.
3. On the **Ancestor Component** page, select an ancestor component from the list.
4. Click **Next**. This displays the **Component** page of the **New VCL Component** wizard.

To specify the class name and other properties

1. On the **Component** page, the fields are prepopulated for **Class Name**, **Palette Page**, **Unit name**, and **Search path**. You can either accept the default values for these fields, or you can change the values by using the following steps. If you want to accept the default values, skip to step 6.
2. To change the default class name, enter a different class name in the **Class Name** textbox.
3. To change the default palette page for the component, in the **Palette Page** textbox, either enter the name of your chosen **Tool Palette** area, or click the down-arrow to select from palette page areas.
4. In the **Unit Name** textbox, you can either enter or edit the full path of the unit name. Click [...] to browse for and select the unit you want.
5. Either enter or edit the search path in the **Search Path** textbox.
6. Click **Next**. This opens the **Create unit** page of the wizard. The choices on the **Create unit** page are:

- **Create Unit**
- **Install to Existing Package**
- **Install to New Package**
- **Add unit to <my_new_package>** (this selection is present only if you create a new package in the very first step, above)

To create a unit

1. On the **Create Unit** page, select the **Create Unit** radio button.
2. Click **Finish**. The new unit opens in the **Code Editor**.

To install a unit into an existing package

1. On the **Create unit** page, select the **Install to Existing Package** radio button.
2. Click **Next**. This generates a list of existing packages.
3. On the **Existing Package** page, select the package you want to install the unit into.
4. Click **Finish**. The new unit opens in the **Code Editor**.

To install a unit into a new package

1. On the **Create unit** page, select the **Install to New Package** radio button.
2. Click **Next**.
3. On the **New Package** page, enter a name for the package into the **File Name** textbox.
4. In the **Description** textbox, enter a description of your new package .
5. Click **Finish**. The new unit opens in the **Code Editor**.

To install a unit into the package created before starting the wizard

1. On the **Create Unit** page, select **Add unit to <my_new_package>.**
2. Click **Finish**. The new unit opens in the **Code Editor**.

VCL Overview (see page 36)

2.5.10 Building a VCL Forms ADO Database Application

The following procedure describes how to build an ADO database application.

Building a VCL ADO application consists of the following major steps:

1. Set up the database connection.
2. Set up the dataset.
3. Set up the data provider, client dataset, and data source.
4. Connect a DataGrid to the connection components.
5. Run the application.

To add an ADO connection component

1. Choose **File** ▶ **New** ▶ **Other** ▶ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** is displayed.
2. From the **dbGo** page of the **Tool Palette**, place an ADOConnection component on the form.
3. Double-click the ADOConnection component to display the **ConnectionString** dialog.
4. If necessary, select **Use Connection String**; then click the **Build** button to display the **Data Link Properties** dialog.
5. On the **Provider** page of the dialog, select **Microsoft Jet 4.0 OLE DB Provider**; then click the **Next** button to display the **Connection** page.
6. On the **Connection** page, click the ellipsis button to browse for the **dbdemos.mdb** database. The default path to this database is C:\Program Files\Common Files\CodeGear Shared\Data.
7. Click **Test Connection** to confirm the connection. A dialog appears, indicating the status of the connection.

8. Click **OK** to close the **Data Link Properties** dialog. Click **OK** to close the **ConnectionString** dialog.

To set up the dataset

1. From the **dbGo** page, place an ADODataSet component at the top of the form.
2. In the **Object Inspector**, select the Connection property drop-down list. Set it to ADOConnection1.
3. Set the CommandText property to an SQL command, for example, Select * from orders. You can either type the Select statement in the **Object Inspector** or click the ellipsis to the right of CommandText to display the **CommandText Editor** where you can build your own query statement.

   Tip: If you need additional help while using the CommandText Editor

   , click the **Help** button.
4. Set the Active property to True to open the dataset. You are prompted to log in. Use admin for the username and no password.

To add the provider

1. From the **Data Access** page, place a DataSetProvider component at the top of the form.
2. In the **Object Inspector**, select the DataSet property drop-down list. Set it to ADODataSet1.

To add client dataset

1. From the **Data Access** page, place a ClientDataSet component to the right of the DataSetProvider component on the form.
2. In the **Object Inspector**, select the ProviderName drop-down. Set it to DataSetProvider1.
3. Set the Active property to True to allow data to be passed to your application. A data source connects the client dataset with data-aware controls. Each data-aware control must be associated with a data source component to have data to display and manipulate. Similarly, all datasets must be associated with a data source component for their data to be displayed and manipulated in data-aware controls on the form.

To add the data source

1. In the **Tool Palette** on the **Data Access** page, place a DataSource component to the right of the ClientDataSet on the form.
2. In the **Object Inspector**, select the DataSet property drop-down. Set it to ClientDataSet1.

To connect a DataGrid to the DataSet

1. In the **Tool Palette** on the **Data Controls** page, place a DBGrid component on the form.
2. In the **Object Inspector**, select the DataSource property drop-down. Set the data source to DataSource1.
3. Choose **Run** ▶ **Run**.
4. You are prompted to log in. Enter admin for the username and no password. The application compiles and displays a VCL form with a DBGrid.

VCL Overview (see page 36)

2.5.11 Building a VCL Forms Application

The following procedure illustrates the essential steps to building a VCL Forms application using RAD Studio.

To create a VCL Form

1. Choose **File** ▶ **New** ▶ **Other** ▶ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The

VCL Forms Designer is displayed.

2. From the **Tool Palette**, place components onto the form to create the user interface.
3. Write the code for the controls.

To associate code with a control

1. Double-click the component on the form to which you want to apply logic. The **Code Editor** displays, cursor in place within the event handler block.
2. Code your application logic.
3. Save and compile the application.

Building a VCL Forms MDI Application Without Using a Wizard (see page 94)

Using ActionManager to Create Actions in a VCL Forms Application (see page 102)

2.5.12 Creating Actions in a VCL Forms Application

Using RAD Studio, the following procedure illustrates how to create actions using the ActionList tool. It sets up a simple application and describes how to create a file menu item with a file open action.

Building the VCL application with ActionList actions consists of the following major steps:

1. Create a main window and add tools for creating a main menu and a File open action.
2. Add the File category to the main menu.
3. Add the File open action to the File category.
4. Build and run the application.

To create a main window

1. Choose **File** ▶ **New** ▶ **Other** ▶ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** displays.
2. From the **Standard** category of the **Tool Palette**, add a TMainMenu and TActionList component to the form.

   Tip: To display icons for nonvisual components such as ActionList1, choose Tools->Options->Environment Options , select VCL Designer from the Delphi options, click Show Component Options, and click **OK**.

To add the File category to the main menu

1. Double-click MainMenu1 on the form. The MainMenu1 editor displays with the first blank command category selected.
2. In the **Object Inspector**, enter &File for the Caption property and press RETURN. File displays on the main menu.
3. Click File on the MainMenu1 editor. The first blank action under the File command displays. Select the blank action.
4. Double-click ActionList1 on the form. The ActionList editor displays.
5. In the editor, select **New Standard Action** from the drop-down list to display the **Standard Action Classes** dialog.
6. Scroll to the File category, and click the TFileOpen action.
7. Click **OK** to close the dialog. File displays in the Categories listbox in the ActionList editor.

8. Click File in the editor. The FileOpen1 action displays in the Action listbox.

To add the File Open action to the File category

1. Double-click MainMenu1, if necessary, to display the MainMenu1 editor; select the blank action under the File category.
2. In the **Object Inspector**, enter &Open for the Caption property and select FileOpen1 from the Action property drop-down list; then press RETURN. Open... displays in the blank action field in the MainMenu1 editor.

To build and run the application

1. Choose **Run** ▶ **Run**. The application executes, displaying a form with the main menu bar and the File menu.
2. Choose **File** ▶ **Open** in the application. The standard **Open** file dialog displays.

VCL Overview (see page 36)

2.5.13 Building a VCL Forms "Hello World" Application

This procedure demonstrates how to construct a simple “Hello world” VCL Forms application using either Delphi or C++. Though simple, the Windows Forms "Hello world" application demonstrates the essential steps for creating a VCL Forms application. The application uses a VCL Form, a control, an event, and displays a dialog in response to a user action.

Creating the "Hello world" application consists of the following steps:

1. Create a VCL Form with a button control.
2. Write the code to display "Hello world" when the button is clicked.
3. Run the application.

To create a VCL Form

1. Choose **File** ▶ **New** ▶ **Other** ▶ **Delphi Projects** or **C++Builder Projects** and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** is displayed.
2. Click the VCL form to display the form view.
3. From the **Standard** page of the Tool Palette, place a TButton component on the form.

To display the "Hello world" string

1. Select Button1 on the form.
2. In the **Object Inspector**, double-click the OnClick action field on the **Events** tab. The **Code Editor** displays, with the cursor in the `Button1Click` event handler block.
3. For Delphi, move the cursor before the `begin` reserved word and then press ENTER. This creates a new line above the code block. For C++, place the cursor after the opening brace ({) and press ENTER.
4. For Delphi, insert the cursor on the new line created, and type the following variable declaration:

```
var s: string;
```

For C++, enter the following code:

```
AnsiString s;
```

5. For Delphi, insert the cursor within the code block and type the following code:

```
s:= 'Hello world!';
ShowMessage(s);
```

For C++, enter the following code:

```
s = “Hello world!”;
ShowMessage( s );
```

To run the "Hello world" application

1. Choose **Run** ▶ **Run** to build and run the application. The form displays with a button called **Button1**.
2. Click **Button1**. A dialog box displays the message "Hello World!"
3. Close the VCL form to return to the IDE.

See Also

VCL Overview (see page 36)

2.5.14 Using ActionManager to Create Actions in a VCL Forms Application

Using RAD Studio, the following procedure illustrates how to create actions using ActionManager. It sets up a simple user interface with a text area, as would be appropriate for a text editing application, and describes how to create a file menu item with a file open action.

Building the VCL application with ActionManager actions consists of the following major steps:

1. Create a main window.
2. Add a File open action to the ActionManager.
3. Create the main menu.
4. Add the action to the menu.
5. Build and run the application.

To create a main window and add a File open action

1. Choose **File** ▶ **New** ▶ **Other** ▶ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** is displayed.
2. From the **Additional** page of the **Tool Palette**, add an TActionManager component to the form.
3. Double-click the TActionManager to display the Action Manager editor.

   Tip: To display captions for nonvisual components such as ActionManager, choose Tools->Environment Options . On the **Designer** tab, check **Show component captions**, and click **OK**.
4. If necessary, click the **Actions** tab.
5. Select **New Standard Action** from the drop-down list to display the **Standard Action Classes** dialog.
6. Scroll to the File category, and click the TFileOpen action.
7. Click **OK** to close the dialog.
8. In the Action Manager editor, select the File category. **Open...** displays in the **Actions:** list box.
9. Click **Close** to close the editor.

To create the main menu

1. From the **Additional** page of the **Tool Palette**, place an TActionMainMenuBar component on the form.
2. Open the Action Manager editor, and select the **File** category from the **Categories:** list box.
3. Drag File to the blank menu bar. File displays on the menu bar.

To build and run the application

1. Choose **Run** ▶ **Run**. The application executes, displaying a form with the main menu bar and the File menu.
2. Choose **File** ▶ **Open**. The Open file dialog displays.

Building a VCL Forms Application (see page 99)

Building a VCL Forms MDI Application Without Using a Wizard (see page 94)

2.5.15 Building a VCL Forms dbExpress Database Application

The following procedure describes how to build a dbExpress database application.

Building a VCL Forms dbExpress application consists of the following major steps:

1. Set up the database connection.
2. Set up the unidirectional dataset.
3. Set up the data provider, client dataset, and data source.
4. Connect a DataGrid to the connection components.
5. Run the application.

To add a dbExpress connection component

1. Choose **File** ▶ **New** ▶ **Other** ▶ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** is displayed.
2. From the **dbExpress** page of the **Tool Palette**, place a TSQLConnection component on the form.
3. Double-click the TSQLConnection component to display the **Connection Editor**.
4. In the **Connection Editor**, set the **Connection Name** field to IBConnection.
5. In the **Connections Setting** box, specify the path to the InterBase database file called employee.gdb in the Database field. By default, the file is located in `C:\Program Files\Common Files\Borland Shared\Data`.
6. Accept the value in the **User_Name** field (`sysdba`) and **Password** field (`masterkey`).
7. Click **OK** to close the **Connection Editor** and save your changes.

To set up the unidirectional dataset

1. In the **Tool Palette** on the **dbExpress** page, place a TSQLDataSet component at the top of the form.
2. In the **Object Inspector**, select the SQLConnection property drop-down list. Set it to TSQLConnection1.
3. Set the CommandText property to an SQL command, for example, `Select * from SALES`. You are prompted to log in. Use the `masterkey` password. For the SQL command, you can either type a Select statement in the Object Inspector or click the ellipsis to the right of CommandText to display the **CommandText Editor** where you can build your own query statement.

   Tip: If you need additional help while using the CommandText Editor

   , click the **Help** button.
4. In the **Object Inspector**, set the Active property to True to open the dataset.

To add the provider

1. In the **Tool Palette** on the **Data Access** page, place a TDataSetProvider component at the top of the form.
2. In the **Object Inspector**, select the DataSet property drop-down list. Set it to SQLDataSet1.

To add client dataset

1. In the **Tool Palette** on the **Data Access** page, place a TClientDataSet component to the right of the TDataSetProvider component on the form.
2. In the **Object Inspector**, select the ProviderName drop-down. Set it to DataSetProvider1.
3. Set the Active property to True to allow data to be passed to your application. A data source connects the client dataset with data-aware controls. Each data-aware control must be associated with a data source component to have data to display and manipulate. Similarly, all datasets must be associated with a data source component for their data to be displayed and manipulated in data-aware controls on the form.

To add the data source

1. In the **Tool Palette** on the **Data Access** page, place a TDataSource component to the right of the TClientDataSet on the form.
2. In the **Object Inspector**, select the DataSet property drop-down. Set it to ClientDataSet1.

To connect a DataGrid to the DataSet

1. In the **Tool Palette** on the **Data Controls** page, place a TDBGrid component on the form.
2. In the **Object Inspector**, select the DataSource property drop-down. Set the data source to DataSource1.
3. Choose **Run** ▶ **Run**. You are prompted to enter a password. Enter `masterkey`. If you enter an incorrect password or no password, the debugger throws an exception. The application compiles and displays a VCL form with a DBGrid.

VCL Overview (see page 36)

2.5.16 Building an Application with XML Components

This example creates a VCL Forms application that uses an XMLDocument component to display contents in an XML file.

The basic steps are:

1. Create an XML document.
2. Create a VCL form.
3. Place an XMLDocument component on the form, and associate it with the XML file.
4. Create VCL components to enable the display of XML file contents.
5. Write event handlers to display XML child node contents.
6. Compile and run the application.

To create the XML document

1. Copy the text below into a file in a text editor.

```
<?xml version="1.0" encoding="UTF-8" standalone="no" ?>
<!DOCTYPE StockHoldings [
    <!ELEMENT StockHoldings (Stock+)>
    <!ELEMENT Stock (name)>
```

```
    <!ELEMENT Stock (price)>
    <!ELEMENT Stock (symbol)>
    <!ELEMENT Stock (shares)>
]>

<StockHoldings>
  <Stock exchange="NASDAQ">
    <name>CodeGear</name>
    <price>10.375</price>
    <symbol>BORL</symbol>
    <shares>100</shares>
  </Stock>

  <Stock exchange="NYSE">
    <name>MyCompany</name>
    <price>8.75</price>
    <symbol>MYCO</symbol>
    <shares type="preferred">25</shares>
  </Stock>
</StockHoldings>
```

2. Save the file to your local drive as an XML document. Give it a name such as `stock.xml`.
3. Open the document in your browser. The contents should display without error.

   Note: In the browser, you can choose View->Source

   to view the source file in the text editor.

To create a form with an XMLDocument component

1. Choose **File** ▶ **New** ▶ **Other** ▶ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** is displayed.
2. From the **Internet** page on the **Tool Palette**, place an TXMLDocument component on the form.
3. In the **Object Inspector**, click the ellipsis button next to the FileName property, browse to the location of the XML file you created, and open it. The XML file is associated with the TXMLDocument component.
4. In the **Object Inspector**, set the Active property to true.

To set up the VCL components

1. From the **Standard** page on the **Tool Palette**, place a TMemo component on the form.
2. From the **Standard** page on the **Tool Palette**, place two TButton components on the form just above **Memo1**.
3. In the **Object Inspector** with **Button1** selected, enter `CodeGear` for the Caption property.
4. In the **Object Inspector** with **Button2** selected, enter `MyCompany` for the Caption property.

To display child node contents in the XML file

1. In the **Object Inspector** with **Button1** selected, double-click the OnClick event on the **Events** tab. The Code displays with the cursor in the `TForm1.Button1Click` event handler block.
2. Enter the following code to display the stock price for the first child node when the CodeGear button is clicked:

```
  BorlandStock:=XMLDocument1.DocumentElement.ChildNodes[0];
  Price:= BorlandStock.ChildNodes['price'].Text;
  Memo1.Text := Price;
IXMLNode *BorlandStock = XMLDocument1->DocumentElement->
            ChildNodes->GetNode(0);
WideString Price = BorlandStock->ChildNodes->
            FindNode( "price" )->Text;
Memo1->Text = Price;
```

3. For Delphi, add a `var` section just above the code block in the event handler, and enter the following local variable declarations:

```
var
     BorlandStock: IXMLNode;
  Price: string;
```

4. In the **Object Inspector** with **Button2** selected, double-click the OnClick event on the **Events** tab. The Code displays with the cursor in the `TForm1.Button2Click` event handler block.
5. Enter the following code to display the stock price for the second child node when the MyCompany button is clicked:

```
  MyCompany:=XMLDocument1.DocumentElement.ChildNodes[1];
  Price:= MyCompany.ChildNodes['price'].Text;
  Memo1.Text := Price;
IXMLNode *MyCompany = XMLDocument1->DocumentElement
       ->ChildNodes->GetNode(1);
WideString Price = BorlandStock->ChildNodes
       ->FindNode( "price" )->Text;
Memo1->Text = Price;
```

6. For Delphi, add a `var` section just above the code block in the event handler, and enter the following local variable declarations:

```
var
  MyCompany: IXMLNode;
  Price: string;
```

To compile and run the application

1. Choose **Run** ▶ **Run** to compile and execute the application. The application form displays two buttons and a memo.
2. Click the **CodeGear** button. The stock price displays.
3. Click the **MyCompany** button. The stock price displays.

VCL Overview (see page 36)

Building a VCL Forms Application (see page 99)

2.5.17 Copying Data From One Stream To Another

Creating this VCL application consists of the following steps:

1. Create a project directory containing a text file to copy.
2. Create a VCL Form with a button control.
3. Write the code to read the string and write it to a file.
4. Run the application.

To set up your project directory and a text file to copy

1. Create a directory in which to store your project files.
2. Using a text editor, create a simple text file and save it as `from.txt` in your project directory.

To create a VCL Form with a button control

1. Choose **File** ▶ **New** ▶ **Other** ▶ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** is displayed.
2. From the **Standard** page of the Tool palette, place a TButton component on the form.
3. In the **Object Inspector**, enter CopyFile for the Caption and Name properties.

To write the copy stream procedure

1. Select Button1 on the form.
2. In the **Object Inspector**, double-click the OnClick action on the **Events** tab. The **Code Editor** displays, with the cursor in the `TForm1.CopyFileClick` (Delphi) or `TForm1::CopyFileClick` (C++) event handler block.
3. For Delphi, Place the cursor before the `begin` reserved word; then press return. This creates a new line above the code block.
4. For Delphi, insert the cursor on the new line created and type the following variable declaration:

```
var stream1, stream2: TStream;
```

For C++, enter the following variable declarations:

```
TStream *stream1, *stream2;
```

5. Insert the cursor within the code block, and type the following code:

```
stream1 := TFileStream.Create('from.txt', fmOpenRead);
try
  stream2:= TFileStream.Create('to.txt', fmCreate);
  try
    stream2.CopyFrom(stream1, stream1.Size);
  finally
    stream2.Free;
  end;
finally
  stream1.Free;
end;
stream1 = new TFileStream( “from.txt”, fmOpenRead );
try {
 stream2 = new TFileStream( “to.txt”, fmCreate );
     try {
   stream2->CopyFrom( stream1, stream1->Size );
 } __finally {
   stream2->Free();
 }
} finally {
 stream1->Free();
}
```

To run the application

1. Save your project files; then choose **Run** ▶ **Run** to build and run the application. The form displays with a button called **CopyFile**.
2. Click **CopyFile**.
3. Use a text editor to open the newly created file to.txt, which is located in your project directory. The contents of from.txt are copied into to.txt.

Building a VCL Forms Application (see page 99)

2.5.18 Copying a Complete String List (VCL)

Copying a string list can have the effect of appending to or overwriting an existing string list. This VCL application appends to a string list. With a simple change, it can overwrite a string list. Creating this VCL application consists of the following steps:

1. Create a VCL Form with TButtons, TComboBox, and TMemo controls.
2. Write the code to create a string list to the Button1 OnClick handler.
3. Write the code to copy the string list to the Button2 OnClick handler.
4. Run the application.

To create a VCL Form with Button, ComboBox, and Memo controls

1. Choose **File** ▶ **New** ▶ **Other** ▶ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** is displayed.
2. From the **Standard** page of the Tool palette, place two TButtons, a TComboBox, and a TMemo component on the form.

To create the string list

1. Select Button1 on the form.
2. In the **Object Inspector**, double-click the OnClick action on the **Events** tab. The **Code Editor** displays, with the cursor in the `TForm1.Button1Click` (Delphi) or `TForm1::Button1Click` (C++) event handler block.
3. For Delphi, place the cursor before the `begin` reserved word; then press `return`. This creates a new line above the code block.
4. For Delphi, insert the cursor on the new line created and type the following variable declarations:

```
var
  StringList: TStrings;
```

For C++, enter the following variable declarations:

```
TStrings *StringList;
```

5. Insert the cursor within the code block, and type the following code:

```
StringList := TStringList.Create;
  try
    with StringList do begin
      Add('This example uses a string List.');
      Add('It is the easiest way to add strings');
      Add('to a combobox''s list of strings.');
      Add('Always remember: the TStrings.Create');
      Add('method is abstract; use the');
      Add('TStringList.Create method instead.');
    end;

    with ComboBox1 do begin
                        Width := 210;
      Items.Assign(StringList);
      ItemIndex := 0;
    end;
  finally
    StringList.free;
  end;
StringList = new TStringList();
try {
 StringList->Add( "This example uses a string list" );
 StringList->Add( "It is the easiest way to add strings" );
 StringList->Add( "to a ComboBox's list of strings." );
 StringList->Add( "Remember to call the TStringList constructor!" );
 ComboBox1->Width = 210;
 ComboBox1->Items->Assign( StringList );
 ComboBox1->ItemIndex = 0;
} __finally {
 StringList->Free();
}
```

To copy the string list

1. Select Button2 on the form.
2. In the **Object Inspector**, double-click the OnClick action on the **Events** tab. The **Code Editor** displays, with the cursor in the `TForm1.Button2Click` (Delphi) or `TForm1::Button2Click` (C++) event handler block. At the cursor, enter the following code:

```
Memo1.Lines.AddStrings(ComboBox1.Items);
Memo1->Lines->AddStrings( ComboBox1->Items
```

To run the application

1. Save your project files; then choose **Run** ▶ **Run** to build and run the application. The form displays with the controls.
2. Click Button1.
3. In ComboBox1, click the arrow to expand the drop-down list. The strings display in the TComboBox in the order listed in the event handler code for Button1.
4. Click Button2. In the Memo1 window, the strings from ComboBox1 are appended to the 'Memo1' string.

   Note: Try replacing the code in the Button2 event handler with the following code; then compile and run the application again.

```
Memo1.Lines.Assign(ComboBox1.Items);
Memo1->Lines->Assign( ComboBox1->Items );
```

The strings from ComboBox1 overwrite the 'Memo1' string.

2.5.19 Creating Strings

Creating this VCL application consists of the following steps:

1. Create a VCL Form with TButton and TComboBox controls.
2. Write the code to create strings to the TButton OnClick handler.
3. Run the application.

To create a VCL Form with TButton and TComboBox controls

1. Choose **File** ▶ **New** ▶ **Other** ▶ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** is displayed.
2. From the **Standard** page of the Tool palette, place a TButton, a TLabel, and a TComboBox component on the form.

To write the create string procedure

1. Select Button1 on the form.
2. In the **Object Inspector**, double-click the OnClick action on the **Events** tab. The **Code Editor** displays, with the cursor in the `TForm1.Button1Click` (Delphi) or `TForm1::Button1Click` (C++) event handler block.
3. For Delphi, place the cursor before the `begin` reserved word; then press `RETURN`. This creates a new line above the code block.
4. For Delphi, insert the cursor on the new line created and type the following variable declarations:

```
var
  StringList: TStrings;
```

For C++, enter the following variable declarations:

```
TStrings *StringList;
```

5. Insert the cursor within the code block, and type the following code:

```
StringList := TStringList.Create;
  try
    with StringList do begin
      Add('Animals');
      Add('Cats');
      Add('Flowers');
    end;

    with ComboBox1 do begin
                        Width := 210;
      Items.Assign(StringList);
      ItemIndex := 0;
    end;

    Label1.Caption := 'Flowers has an index of ' +
      IntToStr( StringList->IndexOf( 'Flowers' ) );
  finally
    StringList.free;
  end;
StringList = new TStringList();
try {
 StringList->Add( “Animals” );
 StringList->Add( “Cats” );
 StringList->Add( “Flowers” );
 ComboBox1–>Width = 210;
 ComboBox1–>Items->Assign( StringList );
 ComboBox1–>ItemIndex = 0;
 Label1–>Caption = “Flowers has an index of “ +
   IntToStr( StringList->IndexOf( “Flowers” ) );
} __finally {
     StringList->Free();
}
```

To run the application

1. Save your project files; then choose **Run** ▶ **Run** to build and run the application. The form displays with the controls.
2. Click the Button. The strings 'Animals', 'Cars', and 'Flowers' display alphabetically in a list in the ListBox. The Label caption displays the message string: 'Flowers has an index value of 2.'
3. In the ComboBox, click the arrow to expand the drop-down list. The strings added in the TButton event handler appear.

VCL Overview (see page 36)

Building a VCL Forms Application (see page 99)

2.5.20 Creating a VCL Form Instance Using a Local Variable

A safe way to create a unique instance of a modal VCL form is to use a local variable in an event handler as a reference to a new instance. If you use a local variable, it doesn't matter whether the form is auto-created or not. The code in the event handler makes no reference to the global form variable. Using RAD Studio, the following procedure creates a modal form instance dynamically. It (optionally) removes the second form's invocation at startup.

Building this VCL application consists of the following steps:

1. Create the project directory.
2. Create two forms for the project.
3. Remove the second form's invocation at startup (optional).
4. Link the forms.
5. Create a control on the main form to create and display the modal form; then write the event handler.
6. Build and run the application.

To create the two forms

1. Choose **File** ▸ **New** ▸ **Other** ▸ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** displays Form1.
2. Choose **File** ▸ **New** ▸ **Other** ▸ **Delphi Projects** ▸ **Delphi Files** or C++Builder Projects and double-click the **Form** icon. The **VCL Forms Designer** displays Form2.

To optionally remove Form2's invocation at startup

1. Choose **Project** ▸ **Options** ▸ **Forms**. The **Project Options** dialog displays.
2. Select Form2 in the **Auto-create forms** list and click **[>]**. Form2 is moved to the **Available forms** list.
3. Click **OK** to close the dialog.

To link Form1 to Form2

1. Select Form1 and choose **File** ▸ **Use Unit** (Delphi) or Include Unit Hdr (C++). The **Uses Unit** dialog displays.
2. Select Form2 (the form that Form1 needs to reference) in the dialog.
3. Click **OK**.

For Delphi, a **uses** clause containing the unit name `Unit2` is placed in the implementation section of Unit1.

For C++, the `#include "Unit2.h"` directive is added to `Unit1.h`.

To display Form2 from Form1

1. Select Form1, if necessary; then, from the **Standard** page of the **Tool Palette**, place a TButton on the form.
2. In the **Object Inspector** with Button1 selected, double-click the OnClick event on the **Events** tab. The **Code Editor** displays with the cursor in the `TForm1.Button1Click` (Delphi) or `TForm1::Button1Click` (C++) event handler block.
3. For Delphi, insert the cursor just above the event handler block and enter the following statement to define a local variable:

```
var FM: TForm2;
```

For C++, enter the following variable declaration:

```
TForm2 *FM;
```

4. Insert the cursor in the event handler block, and enter the following code:

```
FM := TForm2.Create(self);
FM.ShowModal;
FM.Free;
FM = new TForm2( this );
FM->ShowModal();
FM->Free();
```

To build and run the application

1. Save all files in the project; then choose **Run** ▸ **Run**. The application executes, displaying Form1.
2. Click the button. Form2 displays.

3. With Form2 displayed, attempt to click on Form1 to activate it. Nothing happens. Click the X in the upper right corner of Form2. Form2 closes and Form1 becomes the active form.

2.5.21 Deleting Strings

Creating this VCL application consists of the following steps:

1. Create a VCL Form with Buttons and ListBox controls.
2. Write the code to add strings to a list.
3. Write the code to delete a string from the list.
4. Run the application.

To create a VCL Form with TButton and ListBox controls

1. Choose **File** ▸ **New** ▸ **Other** ▸ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** is displayed.
2. From the **Standard** page of the Tool palette, place two TButtons and a TListBox component on the form.
3. Select Button1 on the form.
4. In the **Object Inspector**, enter Add for the Name and Caption properties.
5. Select Button2 on the form.
6. In the **Object Inspector**, enter Delete for the Name and Caption properties.

To add strings to a list

1. Select the **Add** button on the form.
2. In the **Object Inspector**, double-click the OnClick action on the **Events** tab. The **Code Editor** displays, with the cursor in the `TForm1.AddClick` (Delphi) or `TForm1::AddClick` (C++) event handler block.
3. For Delphi, place the cursor before the `begin` reserved word; then press return. This creates a new line above the code block.
4. For Delphi, insert the cursor on the new line created and type the following variable declaration:

```
var
  MyList: TStringList;
```

For C++, enter the following variable declaration:

```
TStringList *MyList;
```

5. Insert the cursor within the code block, and type the following code:

```
MyList := TStringList.Create;
    try
      with MyList do
      begin
        Add('Mice');
        Add('Goats');
```

```
        Add('Elephants');
        Add('Birds');
        ListBox1.Items.AddStrings(MyList);
      end;
    finally
      MyList.Free;
    end;
MyList = new TStringList();
try {
 MyList->Add( “Mice” );
 MyList->Add( “Goats” );
 MyList->Add( “Elephants” );
 MyList->Add( “Birds” );
 ListBox1–>Items->AddStrings( MyList );
} __finally {
 MyList->Free();
}
```

To delete a string from the list

1. Select the **Delete** button on the form.
2. In the **Object Inspector**, double-click the OnClick action on the **Events** tab. The **Code Editor** displays, with the cursor in the `TForm1.DeleteClick` (Delphi) or `TForm1::DeleteClick` (C++) event handler block.
3. For Delphi, place the cursor before the `begin` reserved word; then press `ENTER`. This creates a new line above the code block.
4. For Delphi, insert the cursor on the new line created and type the following variable declaration:

```
var
  BIndex: Integer;
```

For C++, enter the following variable declaration:

```
int BIndex;
```

5. For Delphi, insert the cursor within the code block and type the following code:

```
with ListBox1.Items do
    begin
      BIndex := IndexOf('Elephants');
      Delete (BIndex);
    end;
BIndex = ListBox1–>Items->IndexOf( “Elephants” );
ListBox1–>Items->Delete( BIndex );
```

To run the application

1. Save your project files; then choose **Run** ▶ **Run** to build and run the application. The form displays with the controls.
2. Click the **Add** button. The strings 'Mice', 'Goats', 'Elephants', and 'Birds' display in the order listed.
3. Click the **Delete** button. The string 'Elephants' is deleted from the list.

VCL Overview (see page 36)

Building a VCL Forms Application (see page 99)

2.5.22 Displaying an Auto-Created VCL Form

Using RAD Studio, the following procedure creates a modal form at design time that is displayed later during program execution.

Building this VCL application consists of the following steps:

1. Create the project directory.
2. Create two forms for the project.
3. Link the forms.
4. Create a control on the main form to display the modal form; then write the event handler.
5. Build and run the application.

To create the two forms

1. Choose **File** ▸ **New** ▸ **Other** ▸ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** displays Form1.
2. Choose **File** ▸ **New** ▸ **Other** ▸ **Delphi Projects** ▸ **Delphi Files** or **File** ▸ **New** ▸ **Other** ▸ **C++Builder Files** and double-click the **Form** icon. The **VCL Forms Designer** displays Form2.

To link Form1 to Form2

1. For Delphi, select Form1 and choose **File** ▸ **Use Unit**. For C++, select Form1 and choose **File** ▸ **Include Unit Hdr**. The **Uses Unit** dialog displays.
2. Select Form2 (the form that Form1 needs to reference) in the dialog.
3. Click **OK**.

For Delphi, a **uses** clause containing the unit name Unit2 is placed in the implementation section of Unit1.

For C++, the `#include "Unit2.h"` directive is added to `Unit1.h`.

To display Form2 from Form1

1. Select Form1, if necessary; then, from the **Standard** page of the **Tool Palette**, place a button on the form.
2. In the **Object Inspector** with Button1 selected, double-click the OnClick event on the **Events** tab. The **Code Editor** displays with the cursor in the `TForm1.Button1Click` (Delphi) or `TForm1::Button1Click` (C++) event handler block.
3. Enter the following event handling code:

```
Form2.ShowModal;
Form2->ShowModal();
```

To build and run the application

1. Save all files in the project; then choose **Run** ▸ **Run**. The application executes, displaying Form1.
2. Click the button. Form2 displays.
3. Click the **X** in the upper right corner of Form2. Form2 closes and Form1 becomes the active form.

Dynamically Creating a VCL Modal Form (see page 120)

2.5.23 Displaying a Bitmap Image in a VCL Forms Application

This procedure loads a bitmap image from a file and displays it to a VCL form.

1. Create a VCL form with a button control.
2. Provide a bitmap image.
3. Code the button's onClick event handler to load and display a bitmap image.
4. Build and run the application.

To create a VCL form and button

1. Choose **File** ▶ **New** ▶ **Other** ▶ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** is displayed.
2. From the **Standard** page of the **Tool Palette**, place a TButton component on the form.

To provide a bitmap image

1. Create a directory in which to store your project files.
2. Locate a bitmap image on your local drive, and copy it to your project directory.
3. Save all files in your project to your project directory.

To write the OnClick event handler

1. In the **Object Inspector**, double-click the Button1 OnClick event on the **Events** tab. The **Code Editor** displays with the cursor in the `TForm1.Button1Click` (Delphi) or `TForm1::Button1Click` (C++) event handler block.
2. Enter the following event handling code, replacing `MyFile.bmp` with path to the bitmap image in your project directory:

```
Bitmap := TBitmap.Create;
try
  Bitmap.LoadFromFile('MyFile.bmp');
  Form1.Canvas.Brush.Bitmap := Bitmap;
  Form1.Canvas.FillRect(Rect(0,0,100,100));
finally
  Form1.Canvas.Brush.Bitmap := nil;
  Bitmap.Free;
end;
```

```
Graphics::TBitmap *Bitmap = new Graphics::TBitmap();
try {
  Bitmap->LoadFromFile( "..\\MyFile.bmp" );
  Form1->Canvas->Brush->Bitmap = Bitmap;
  Form1->Canvas->FillRect( Rect(0,0,100,100) );
} __finally {
  Form1->Canvas->Brush->Bitmap = NULL;
  Bitmap->Free();
}
```

Note: For C++ projects, the code assumes the target output directory is located in the project directory.

Tip: You can change the size of the rectangle to be displayed by adjusting the `Rect` parameter values.

3. For Delphi, add the following variable declaration in the **var** block:

```
Bitmap : TBitmap;
```

To run the program

1. Select **Run** ▶ **Run**.
2. Click the button to display the image bitmap in a 100 x 100-pixel rectangle in the upper left corner of the form.

Placing A Bitmap Image In a Combo Box of a VCL Application (see page 135)

2.5.24 Displaying a Full View Bitmap Image in a VCL Forms Application

This procedure loads a bitmap image from a file and displays it in its entirety to a VCL form. The procedure uses the Height and Width properties of the Bitmap object to display a full view of the image.

1. Create a VCL form with a button control.
2. Provide a bitmap image.
3. Code the button's onClick event handler to load and display a bitmap image.
4. Build and run the application.

To create a VCL form and button

1. Choose **File** ▶ **New** ▶ **Other** ▶ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** is displayed.
2. From the **Standard** page of the **Tool Palette**, place a button component on the form.
3. In the **Object Inspector**, enter Full View for the Caption property and FullView for the name property.

To provide a bitmap image

1. Create a directory in which to store your project files.
2. Locate a bitmap image on your local drive, and copy it to your project directory.
3. Save all files in your project to your project directory.

To write the OnClick event handler

1. In the **Object Inspector**, double-click the Button1 OnClick event on the **Events** tab. The **Code Editor** displays with the cursor in the `TForm1.FullViewClick` (Delphi) or `TForm1::FullViewClick` (C++) event handler block.
2. Enter the following event handling code, replacing `MyFile.bmp` with the name of the bitmap image in your project directory:

```
      Bitmap := TBitmap.Create;
      try
        Bitmap.LoadFromFile('MyFile.bmp');
        Form1.Canvas.Brush.Bitmap := Bitmap;
        Form1.Canvas.FillRect(Rect(0,0,Bitmap.Width,Bitmap.Height));
      finally
        Form1.Canvas.Brush.Bitmap := nil;
        Bitmap.Free;
      end;
```

```
Graphics::TBitmap Bitmap = new Graphics::TBitmap();
try {
  Bitmap->LoadFromFile( “..\\MyFile.bmp” );
  Form1–>Canvas->Brush->Bitmap = Bitmap;
  Form1–>Canvas->FillRect(
    Rect( 0, 0, Bitmap->Width, Bitmap->Height ) );
} __finally {
  Form1–>Canvas->Brush->Bitmap = NULL;
  Bitmap->Free();
}
```

Note: For C++ projects, the code assumes the target output directory is located in the project directory.

3. For Delphi, add the following variable declaration in the **var** block:

```
Bitmap : TBitmap;s
```

To run the program

1. Choose **Run** ▶ **Run**.
2. Click the button to display the image bitmap in a rectangle in the upper left corner of the form.

Drawing Rectangles and Ellipses in a VCL Forms Application (see page 118)

Drawing a Polygon in a VCL Forms Application (see page 117)

Placing A Bitmap Image In a Combo Box of a VCL Forms Application (see page 135)

2.5.25 Drawing a Polygon in a VCL Forms Application

This procedure draws a polygon in a VCL form.

1. Create a VCL form.
2. Code the form's OnPaint event handler to draw a polygon.
3. Build and run the application.

To create a VCL form

1. Choose **File** ▶ **New** ▶ **Other** ▶ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** is displayed.
2. In the form view, click the form, if necessary, to display Form1 in the **Object Inspector**.

To write the OnPaint event handler

1. In the **Object Inspector**, click the **Events** tab.
2. Double-click the OnPaint event. The **Code Editor** displays with the cursor in the `TForm1.FormPaint` (Delphi) or `TForm1::FormPaint` (C++) event handler block.
3. Enter the following event handling code:

```
Canvas.Polygon ([Point(0,0), Point(0, ClientHeight),
Point(ClientWidth, ClientHeight)]);
TPoint points[] = { Point(0,0),
                    Point(0, ClientHeight),
                    Point(ClientWidth, ClientHeight) };
Canvas->Polygon( points, 3 );
```

To run the program

1. Select **Run** ▶ **Run**.
2. The applications executes, displaying a right triangle in the lower left half of the form.

Displaying a Bitmap Image in a VCL Forms Application (see page 114)

2.5.26 Drawing Rectangles and Ellipses in a VCL Forms Application

This procedure draws a rectangle and ellipse in a VCL form.

1. Create a VCL form.
2. Code the form's OnPaint event handler to draw a rectangle and ellipse.
3. Build and run the application.

To create a VCL form and place an image on it

1. Choose **File** ▶ **New** ▶ **Other** ▶ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** is displayed.
2. In the form view, click the form, if necessary, to display Form1 in the **Object Inspector**.

To write the OnPaint event handler

1. In the **Object Inspector**, double-click the Form1 OnPaint event on the Events tab. The **Code Editor** displays with the cursor in the `TForm1.FormPaint` (Delphi) or `TForm1::FormPaint` (C++) event handler block.
2. Enter the following event handling code:

```
Canvas.Rectangle (0, 0, ClientWidth div 2, ClientHeight div 2);
Canvas.Ellipse (0, 0, ClientWidth div 2, ClientHeight div 2);
Canvas->Rectangle( 0, 0, ClientWidth / 2, ClientHeight / 2 );
Canvas->Ellipse( 0, 0, ClientWidth / 2, ClientHeight / 2 );
```

To run the program

1. Choose **Run** ▶ **Run**.
2. The applications executes, displaying a rectangle in the upper left quadrant, and an ellipse in the same area of the form.

2.5.27 Drawing a Rounded Rectangle in a VCL Forms Application

This procedure draws a rounded rectangle in a VCL form.

1. Create a VCL form and code the form's OnPaint event handler.
2. Build and run the application.

To create a VCL form

1. Choose **File** ▸ **New** ▸ **Other** ▸ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** is displayed.
2. In the **Object Inspector**, click the **Events** tab.
3. Double-click the OnPaint event. The **Code Editor** displays with the cursor in the `TForm1.FormPaint` (Delphi) or `TForm1::FormPaint` (C++) event handler block.
4. Enter the following event handling code:

```
Canvas.RoundRect(0, 0, ClientWidth div 2,
  ClientHeight div 2, 10, 10);
Canvas->RoundRect( 0, 0, ClientWidth / 2, ClientHeight / 2, 10, 10 );
```

To run the program

1. Save all files in your project; then choose **Run** ▸ **Run**.
2. The application executes, displaying a rounded rectangle in the upper left quadrant of the form.

See Also

VCL Overview (see page 36)

Drawing Rectangles and Ellipses in a VCL Forms Application (see page 118)

2.5.28 Drawing Straight Lines In a VCL Forms Application

This procedure draws two diagonal straight lines on an image in a VCL form.

1. Create a VCL form.
2. Code the form's OnPaint event handler to draw the straight lines.
3. Build and run the application.

To create a VCL form and place an image on it

1. Choose **File** ▸ **New** ▸ **Other** ▸ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** is displayed.
2. In the form view, click the form, if necessary, to display Form1 in the **Object Inspector**.

To write the OnPaint event handler

1. In the **Object Inspector**, double-click the Form1 OnPaint event on the **Events** tab. The **Code Editor** displays with the cursor in the `TForm1.FormPaint` event handler block.
2. Enter the following event handling code:

```
with Canvas do
begin
MoveTo(0,0);
LineTo(ClientWidth, ClientHeight);
MoveTo(0, ClientHeight);
LineTo(ClientWidth, 0);
end;
Canvas->MoveTo( 0, 0 );
Canvas->LineTo( ClientWidth, ClientHeight );
Canvas->MoveTo( 0, ClientHeight );
Canvas->LineTo( ClientWidth, 0 );
```

To run the program

1. Choose **Run** ▶ **Run**.
2. The applications executes, displaying a form with two diagonal crossing lines.

   Tip: To change the color of the pen to green, insert this statement following the first `MoveTo()` statement in the event handler code: `Pen.Color := clGreen;` (Delphi) `Canvas->Pen->Color = clGreen;` (C++). Experiment using other canvas and pen object properties. See "Using the properties of the Canvas object" in the Delphi 7 Developer's Guide.

2.5.29 Dynamically Creating a VCL Modal Form

You may not want all your VCL application's forms in memory at once. To reduce the amount of memory required at load time, your application can create forms only when it needs to make them available for use. A dialog box, for example, needs to be in memory only during the time the user interacts with it. Using RAD Studio, the following procedure creates a modal form dynamically. The main difference between dynamically creating a form and displaying an auto-created VCL form is that you remove the second form's invocation at startup and write code to dynamically create the form.

Building this VCL application consists of the following steps:

1. Create the project directory.
2. Create two forms for the project.
3. Remove the second form's invocation at startup.
4. Link the forms.
5. Create a control on the main form to create and display the modal form; then write the event handler.
6. Build and run the application.

To create the two forms

1. Choose **File** ▶ **New** ▶ **Other** ▶ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** displays Form1.
2. Choose **File** ▶ **New** ▶ **Other** ▶ **Delphi Projects** ▶ **Delphi Files** or **File** ▶ **New** ▶ **Other** ▶ **C++Builder Files** and double-click the **Form** icon. The **VCL Forms Designer** displays Form2.

To remove Form2's invocation at startup

1. Choose **Project** ▶ **Options** ▶ **Forms**. The **Project Options** dialog displays.
2. Select Form2 in the **Auto-create forms** list and click **[>]**. Form2 is moved to the **Available forms** list.
3. Click **OK** to close the dialog.

To link Form1 to Form2

1. For Delphi, select Form1 and choose **File** ▸ **Use Unit**. For C++, select Form1 and choose **File** ▸ **Include Unit Hdr** The **Uses Unit** dialog displays.
2. Select Form2 (the form that Form1 needs to reference) in the dialog.
3. Click **OK**. For Delphi, a **uses** clause containing the unit name Unit2 is placed in the implementation section of Unit1. For C++, the `#include "Unit2.h"` directive is added to `Unit1.h`.

To display Form2 from Form1

1. Select Form1, if necessary; then, from the **Standard** page of the **Tool Palette**, place a TButton on the form.
2. In the **Object Inspector** with Button1 selected, double-click the OnClick event on the **Events** tab. The **Code Editor** displays with the cursor in the `TForm1.Button1Click` (Delphi) or `TForm1::Button1Click` (C++) event handler block.
3. Enter the following event handling code:

```
Form2 := TForm2.Create(self);
try
  Form2.ShowModal;
finally
  Form2.Free;
end;
Form2 = new TForm2( this );
try {
  Form2->ShowModal();
} __finally {
  Form2->Free();
}
```

To build and run the application

1. Save all files in the project; then choose **Run** ▸ **Run**. The application executes, displaying Form1.
2. Click the button. Form2 displays.
3. Click the **X** in the upper right corner of the form. Form2 closes and Form1 becomes the active form.

Dynamically Creating a VCL Modeless Form (see page 121)

Displaying an Auto-Created VCL Form (see page 113)

2.5.30 Dynamically Creating a VCL Modeless Form

A modless form is a window that is displayed until it is either obscured by another window or until it is closed or minimuzed by the user. Using RAD Studio, the following procedure creates a modeless form dynamically.

Building this VCL application consists of the following steps:

1. Create the project directory.
2. Create two forms for the project.
3. Remove the second form's invocation at startup.
4. Link the forms.

5. Create a control on the main form to create and display the modal form; then write the event handler.
6. Build and run the application.

To create the two forms

1. Choose **File** ▸ **New** ▸ **Other** ▸ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** displays Form1.
2. Choose **File** ▸ **New** ▸ **Other** ▸ **Delphi Projects** ▸ **Delphi Files** or **File** ▸ **New** ▸ **Other** ▸ **C++Builder Files** and double-click the **Form** icon. The **VCL Forms Designer** displays Form2.

To remove Form2's invocation at startup

1. Choose **Project** ▸ **Options**. The **Project Options** dialog displays.
2. Select Form2 in the **Auto-create forms** list and click **[>]**. Form2 is moved to the **Available forms** list.
3. Click **OK** to close the dialog.

To link Form1 to Form2

1. For Delphi, select Form1 and choose **File** ▸ **Use Unit**. For C++, select Form1 and choose **File** ▸ **Include Unit Hdr**. The **Uses Unit** dialog displays.
2. Select Form2 (the form that Form1 needs to reference) in the dialog.
3. Click **OK**. For Delphi, a **uses** clause containing the unit name Unit2 is placed in the implementation section of Unit1. For C++, the `#include "Unit2.h"` directive is added to `Unit1.h`.

To display Form2 from Form1

1. Select Form1, if necessary; then, from the **Standard** page of the **Tool Palette**, place a button on the form.
2. In the **Object Inspector** with Button1 selected, double-click the OnClick event on the **Events** tab. The **Code Editor** displays with the cursor in the `TForm1.Button1Click` (Delphi) or `TForm1::Button1Click` (C++)event handler block.
3. Enter the following event handling code:

```
Form2 := TForm2.Create(self);
Form2.Show;
Form2 = new TForm2( this );
Form2->Show();
```

Note: If your application requires additional instances of the modeless form, declare a separate global variable for each instance. In most cases you use the global reference that was created when you made the form (the variable name that matches the Name property of the form).

To build and run the application

1. Save all files in the project; then choose **Run** ▸ **Run**. The application executes, displaying Form1.
2. Click the button. Form2 displays.
3. Click Form1. Form1 becomes the active form. Form2 displays until you minimize or close it.

Dynamically Creating a VCL Modal Form (see page 120)

2.5.31 Iterating Through Strings in a List

This VCL application first creates a list of strings. Then it iterates through the strings, changing all string characters to uppercase. It consists of the following steps:

1. Create a VCL Form with Buttons and TListBox controls.
2. Write the code to create a string list and add strings to it.
3. Write the code to iterate through the string list to process string characters.
4. Run the application.

To create a VCL Form with TButton and TListBox controls

1. Choose **File** ▶ **New** ▶ **Other** ▶ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** is displayed.
2. From the **Standard** page of the Tool palette, place two TButtons and a TListBox component on the form.
3. Select Button1 on the form.
4. In the **Object Inspector**, enter Add for the Name and Caption properties.
5. Select Button2 on the form.
6. In the **Object Inspector**, enter ToUpper for the Name and Caption properties.

To create a string list and add strings to it

1. Select the **Add** button on the form.
2. In the **Object Inspector**, double-click the OnClick action on the **Events** tab. The **Code Editor** displays, with the cursor in the `TForm1.AddClick` (Delphi) or `TForm1::AddClick` (C++) event handler block.
3. For Delphi, place the cursor before the `begin` reserved word; then press ENTER. This creates a new line above the code block.
4. For Delphi, insert the cursor on the new line created, and type the following variable declaration:

```
var
  MyList: TStringList;
```

5. Insert the cursor within the code block, and type the following code:

```
MyList := TStringList.Create;
    try
      with MyList do
      begin
        Add('Mice');
        Add('Goats');
        Add('Elephants');
        Add('Birds');
        ListBox1.Items.AddStrings(MyList);
      end;
    finally
      MyList.Free;
    end;
TStringList *MyList = new TStringList();
try {
 MyList->Add(“Mice”);
 MyList->Add(“Goats”);
 MyList->Add(“Elephants”);
 MyList->Add(“Birds”);
 ListBox1–>Items->AddStrings( MyList );
```

```
} __finally {
 MyList->Free();
}
```

To change all characters to uppercase

1. Select the **ToUpper** button on the form.
2. In the **Object Inspector**, double-click the OnClick action on the **Events** tab. The **Code Editor** displays, with the cursor in the `TForm1.ToUpperClick` (Delphi) or `TForm1::ToUpperClick` (C++) event handler block.
3. For Delphi, place the cursor before the `begin` reserved word; then press return. This creates a new line above the code block.
4. For Delphi, insert the cursor on the new line created and type the following variable declaration:

```
var
 Index: Integer;
```

5. Insert the cursor within the code block, and type the following code:

```
for Index := 0 to ListBox1.Items.Count - 1 do
    ListBox1.Items[Index] := UpperCase(ListBox1.Items[Index]);
for( int i = 0; i < ListBox1->Items->Count; i++ ) {
 ListBox1->Items[i] = UpperCase( ListBox1->Items[i] );
}
```

To run the application

1. Save your project files; then choose **Run** ▶ **Run** to build and run the application. The form displays with the controls.
2. Click the **Add** button. The strings 'Mice', 'Goats', 'Elephants', and 'Birds' display in the order listed.
3. Click the **ToUpper** button. The string characters display in uppercase.

Building a VCL Forms Application (see page 99)

2.5.32 Building a Multithreaded Application

These are the essential steps to building a VCL Forms multithreaded application with a thread object using RAD Studio.

To drop a component on a form

1. Create a VCL form with a defined thread object.
2. Optionally initialize the thread.
3. Write the thread function.
4. Optionally write the cleanup code.

See Also

VCL Overview (see page 36)

Defining a Thread Object (see page 126)

Initializing a Thread (see page 130)

Writing the Thread Function (see page 134)

Writing Cleanup Code (see page 125)

2.5.33 Writing Cleanup Code

To clean up after your thread finishes executing

1. Centralize the cleanup code by placing it in the OnTerminate event handler. This ensures that the code gets executed.
2. Do not use any thread-local variables, because OnTerminate is not run as part of your thread.
3. You can safely access any objects from the OnTerminate handler.

See Also

VCL Overview (see page 36)

Building a Multithreaded Application (see page 124)

2.5.34 Avoiding Simultaneous Thread Access to the Same Memory

Use these basic techniques to prevent other threads from accessing the same memory as your thread:

1. Lock objects.
2. Use critical sections.
3. Use a multi-read exclusive-write synchronizer

To lock objects

1. For objects such as canvas that have a `Lock` method, call the `Lock` method, as necessary, to prevent other objects from accessing the object, and call `Unlock` when locking is no longer required.
2. Call `TThreadList.LockList` (Delphi) or `TThreadList::LockList()` (C++) to block threads from using the list object `TThreadList`, and call `TThreadList.UnlockList` when locking is no longer required.

   Note: You can safely make calls to `TCanvas.Lock` and `TThreadList.LockList`.

To use a critical section

1. Create a global instance of `TCriticalSection`.
2. Call the `Acquire` method to lock out other threads while accessing global memory.
3. Call the `Release` method so other threads can access the memory by calling `Acquire`. The following code has a global critical section variable `LockXY` that blocks access to the global variables `X` and `Y`. To use `X` or `Y`, a thread must surround that use with calls to the critical section such as shown here:

```
LockXY.Acquire;
try
      X := X + 1;
  Y := sin(X);
finally
  LockXY.Release
end;
LockXY->Acquire();
try {
  x++;
  y = sin( x );
```

```
} __finally {
  LockXY->Release();
}
```

Warning: Critical sections only work if every thread uses them to access global memory. Otherwise, problems of simultaneous access can occur.

To use the multi-read exclusive-write synchronizer

1. Create a global instance of `TMultiReadExclusiveWriteSynchronizer` that is associated with the global memory you want to protect.
2. Before any thread reads from the memory, it must call `BeginRead`.
3. At the completion of reading memory, the thread must call `EndRead`.
4. Before any thread writes to the memory, it must call `BeginWrite`.
5. At the completion of writing to the memory, the thread must call `EndWrite`.

   Warning: The multi-read exclusive-write synchronizer only works if every thread uses it to access the associated global memory. Otherwise, problems of simultaneous access can occur.

See Also

VCL Overview (see page 36)

Writing the Thread Function (see page 134)

Using the Main VCL Thread (see page 131)

Waiting for Threads (see page 132)

Handling Exceptions (see page 129)

2.5.35 Defining the Thread Object

To define the thread object

1. Choose **File** ▶ **New** ▶ **Other** ▶ **Delphi Projects** ▶ **Delphi Files** or **File** ▶ **New** ▶ **Other** ▶ **C++Builder Files** and double-click the **Thread Object** icon. The **New Thread Object** dialog displays.
2. Enter a class name, for example, `TMyThread`.
3. Optionally check the **Named Thread** check box, and enter a name for the thread, for example, MyThreadName.

   Tip: Entering a name for Named Thread makes it easier to track the thread while debugging.

4. Click **OK**.

The **Code Editor** displays the skeleton code for the thread object.

The code generated for the new unit will look like this if you named your thread class TMyThread.

```
unit Unit1;

interface

uses
  Classes;

type
  TMyThread = class(TThread)
  private
```

```
    { Private declarations }
  protected
    procedure Execute; override;
  end;

implementation

{ Important: Methods and properties of objects in visual components can only be
  used in a method called using Synchronize, for example,

      Synchronize(UpdateCaption);

  and UpdateCaption could look like,

    procedure TMyThread.UpdateCaption;
    begin
      Form1.Caption := 'Updated in a thread';
    end; }

{ TMyThread }

procedure TMyThread.Execute;
begin
  { Place thread code here }
end;

end.
```

Adding a name for the thread generates additional code for the unit. It includes the Windows unit, adds the procedure (Delphi) or function (C++) `SetName`, and adds the record `TThreadNameInfo` (Delphi) or struct `THREADNAME_INFO` (C++). The name is assigned to the `FName` field, as shown here:

```
unit Unit1;

interface

uses
  Classes {$IFDEF MSWINDOWS} , Windows {$ENDIF};

type
  TMyThread = class(TThread)
  private
    procedure SetName;
  protected
    procedure Execute; override;
  end;

implementation

{ Important: Methods and properties of objects in visual components can only be
  used in a method called using Synchronize, for example,

      Synchronize(UpdateCaption);

  and UpdateCaption could look like,

    procedure TMyThread.UpdateCaption;
    begin
      Form1.Caption := 'Updated in a thread';
    end; }

{$IFDEF MSWINDOWS}
type
  TThreadNameInfo = record
    FType: LongWord;     // must be 0x1000
    FName: PChar;        // pointer to name (in user address space)
```

```
    FThreadID: LongWord; // thread ID (-1 indicates caller thread)
    FFlags: LongWord;    // reserved for future use, must be zero
  end;
{$ENDIF}

{ TMyThread }

procedure TMyThread.SetName;
{$IFDEF MSWINDOWS}
var
  ThreadNameInfo: TThreadNameInfo;
{$ENDIF}
begin
{$IFDEF MSWINDOWS}
  ThreadNameInfo.FType := $1000;
  ThreadNameInfo.FName := 'MyThreadName';
  ThreadNameInfo.FThreadID := $FFFFFFFF;
  ThreadNameInfo.FFlags := 0;

  try
    RaiseException( $406D1388, 0, sizeof(ThreadNameInfo) div sizeof(LongWord), @ThreadNameInfo
);
  except
  end;
{$ENDIF}
end;

procedure TMyThread.Execute;
begin
  SetName;
  { Place thread code here }
end;

end.
// Unit1.h

#ifndef Unit1H
#define Unit1H
#include <Classes.hpp>
class TMyThread : public TThread
{
  typedef struct tagTHREADNAME_INFO
  {
    DWORD dwType;
    LPCSTR szName;
    DWORD dwThreadID;
    DWORD dwFlags;
  } THREADNAME_INFO;
private:
  void SetName();
protected:
  void __fastcall Execute();
public:
  __fastcall TMyThread(bool CreateSuspended);
};

#endif
// Unit1.cpp
#include "Unit3.h"
#pragma package(smart_init)

__fastcall TMyThread::TMyThread(bool CreateSuspended)
  : TThread(CreateSuspended)
{
}
```

```
void TMyThread::SetName()
{
  THREADNAME_INFO info;
  info.dwType = 0x1000;
  info.szName = "TMyThreadName";
  info.dwThreadID = -1;
  info.dwFlags = 0;

  __try
  {
     RaiseException( 0x406D1388, 0, sizeof(info)/sizeof(DWORD),(DWORD*)&info; );
  }
  __except (EXCEPTION_CONTINUE_EXECUTION)
  {
  }
}

void __fastcall TMyThread::Execute()
{
  SetName();
  //---- Place thread code here ----
}
```

Writing the Thread Function (see page 134)

Writing Cleanup Code (see page 125)

2.5.36 Handling Exceptions

To handle exceptions in the thread function

1. Add a **try...except** block to the implementation of your `Execute` method.
2. Code the logic such as shown here:

```
procedure TMyThreadExecute;
begin
  try
    while not Terminated do
      PerformSomeTask;
  except
    {do something with exceptions}
  end;
end;
void __fastcall TMyThread::Execute() {
  try {
    while( !Terminated() ) {
      // perform tasks
    }
  } catch(...) { // catch specific exceptions first
    // exception–handling code
  }
}
```

Using the Main VCL Thread (see page 131)

Avoiding Simultaneous Thread Access to the Same Memory (see page 125)

Waiting for Threads (see page 132)

2.5.37 Initializing a Thread

To initialize a thread object

1. Assign a default thread priority.
2. Indicate when the thread is freed.

To assign a default priority

1. Assign a default priority to the thread from the values listed in the table below. Use a high-priority to handle time critical tasks, and a low priority to perform other tasks.

Value	Priority
tpIdle	The thread executes only when the system is idle. Windows won't interrupt the other threads to execute a thread with tpIdle priority.
tpLowest	The thread's priority is two points below normal.
tpLower	The thread's priority is one point below normal.
tpNormal	The thread has normal priority.
tpHigher	The thread's priority is one point above normal.
tpHighest	The thread's priority is two points above normal.
tpTimeCritical	The thread gets highest priority.

2. Override the `Create` method (Delphi) or default constructor (C++) of the thread class by adding a new constructor to the declaration.
3. Code the constructor. The following is an example for a low-priority thread:

```
constructor TMyThread.Create(CreateSuspended: Boolean);
begin
  inherited Create(CreateSuspended);
  Priority := tpIdle;
end;
TMyThread::TMyThread( bool CreateSuspended ) : TThread( CreateSuspended ) {
  Priority = tpIdle;
}
```

4. Indicate whether the thread should be freed automatically when it finishes executing.

   Warning: Boosting the thread priority of a CPU intensive operation may starve other threads in the application. Only apply priority boosts to threads that spend most of their time waiting for external events.

To indicate when a thread is freed

1. Set the `FreeOnTerminate` property to **true**, unless the thread must be coordinated with other threads.
2. If the thread requires coordination with another thread, set `FreeOnTerminate` to **false**; then explicitly free the first thread from the second.

Defining a Thread Object (see page 126)

Writing the Thread Function (see page 134)

Writing Cleanup Code (see page 125)

2.5.38 Using the Main VCL Thread

Using the main VCL thread consists of the following basic steps:

1. Create a separate routine to handle Windows messages received by components in your application.
2. Call CheckSynchronize periodically.
3. Declare thread-local variables, as necessary, for exclusive use by your thread.

To create a separate routine

1. Write a main thread routine that handles accessing object properties and executing object methods for all objects in your application.
2. Call the routine using the `TThread.Synchronize` (Delphi) or `TThread::Synchronize` method. The following code is an example of how to call a method using `Synchronize`

```
procedure TMyThread.PushTheButton
begin
  Button1.Click;
end;
procedure TMyThread.Execute;
begin
  ...
  Synchronize(PushThebutton);
  ...
end;
void TMyThread::PushTheButton() { Form1->Button1->Click(); }
void __fastcall TMyThread::Execute() {
  ...
  Synchronize( (TThreadMethod)&PushTheButton );
  ...
}
```

`Synchronize` waits for the main thread to enter the message loop and then executes the passed method.

Note: Because `Synchronize` uses a message loop, it does not work in console applications. For console applications, use other mechanisms, such as critical sections, to protect access to VCL objects.

To call CheckSynchronize

1. Call `CheckSynchronize` periodically within the main thread to enable background threads to synchronize execution with the main thread.
2. To ensure the safety of making background thread calls, call `CheckSynchronize` when the application is idle, for example, from an `OnIdle` event handler.

To use a thread-local variable

1. Identify variables that you want to make global to all the routines running in your thread but not shared by other instances of the same thread class.

2. For Delphi, declare these variables in a **threadvar** section, for example,

```
threadvar
  x: integer;
```

For C++, declare these variables with the __**thread** modifier:

```
int __thread x;
```

Note: Use the threadvar

section for global variables only. Do not use it for Pointer and Function variables or types that use copy-on-write semantics, such as long strings.

Note: For C++, if you initialize a __thread

variable, you must initialize it to a constant expression. For example, `int __thread foo = 3;` is a legal statement, but `int __thread foo = get_value();` is not permitted because the initialization occurs at runtime.

VCL Overview (see page 36)

Writing the Thread Function (see page 134)

Avoiding Simultaneous Thread Access to the Same Memory (see page 125)

Waiting for Threads (see page 132)

Handling Exceptions (see page 129)

2.5.39 Waiting for Threads

The following are procedures that can be used to wait for threads.

- Wait for a thread to finish executing.
- Wait for a task to complete.
- Check if another thread is waiting for your thread to terminate.

To wait for a thread to finish executing

1. Use the `WaitFor` method of the other thread.
2. Code your logic. For example, the following code waits for another thread to fill a thread list object before accessing the objects in the list:

```
if ListFillingThread.WaitFor then
begin
  with ThreadList1.LockList do
  begin
               for I := 0 to Count - 1 do
      ProcessItem(Items[I];
  end;
  ThreadList1.UnlockList;
end;
if( ListFillingThread->WaitFor() ) {
  TList* list = ThreadList1->LockList();
  for( int i = 0; i < list->Count; i++ ) {
    DoSomething( list->Items[i] );
  }
  ThreadList1->UnlockList();
}
```

To wait for a task to complete

1. Create a TEvent object of global scope.
2. When a thread completes an operation other threads are waiting for, have the thread call `TEvent.SetEvent`.
3. To turn off the signal, call `TEvent.ResetEvent`.

The following example is an OnTerminate event handler that uses a global counter in a critical section to keep track of the number of terminating threads. When `Counter` reaches 0, the handler calls the `SetEvent` method to signal that all processes have terminated:

```
procedure TDataModule.TaskTerminateThread(Sender: TObject);
begin
  ...
  CounterGuard.Acquire; {obtain a lock on the counter}
  Dec(Counter); {decrement the global counter variable}
  if Counter = 0 then
    Event1.SetEvent; {signal if this is the last thread}
  Counter.Release; {release the lock on the counter}
  ...
end;
void __fastcall TDataModule::TaskThreadTerminate( TObject *Sender ) {
  ...
  CounterGuard->Acquire(); // lock the counter
  if( --Counter == 0 )      // decrement counter
    Event1->SetEvent();    // signal if this is the last thread
  CounterGuard->Release(); // release lock
}
```

The main thread initializes `Counter`, launches the task threads, and waits for the signal that they are all done by calling the `TEvent::WaitFor` method. `WaitFor` waits a specified time period for the signal to be set and returns one of the values in the table below.

The following code example shows how the main thread launches the task threads and resumes when they have completed.

```
Event1.ResetEvent; {clear the event before launching the threads}
for i := 1 to Counter do
  TaskThread.Create(False); {create and launch the task threads}
if Event1.WaitFor(20000) <> wrSignaled then
  raise Exception;
{continue with main thread}
Event1->ResetEvent();  // clear the event before launching threads
for( int i = 0; i < Counter; i++ ) {
  new TaskThread( false );
if( Event1->WaitFor(20000) != wrSignaled )
  throw Exception;
// now continue with the main thread
```

Note: If you do not want to stop waiting for an event handler after a specified time period, pass the `WaitFor` method a parameter value of INFINITE. Be careful when using INFINITE, because your thread will hang if the anticipated signal is never received.

To check if another thread is waiting on your thread to terminate

1. In your `Execute` procedure, implement the `Terminate` method by checking and responding to the `Terminated` property.
2. This is one way to code the logic:

```
procedure TMyThread.Execute;
begin
  while not Terminated do
    PerformSomeTask;
end;
void __fastcall TMyThread::Execute() {
  while( !Terminated )
```

```
    DoSomething();
}
```

WaitFor return values

Value	Meaning
wrSignaled	The signal of the event was set.
wrTimeout	The specified time elapsed without the signal being set.
wrAbandoned	The event object was destroyed before the timeout period elapsed.
wrError	An error occurred while waiting.

Avoiding Simultaneous Thread Access to the Same Memory (see page 125)

Handling Exceptions (see page 129)

2.5.40 Writing the Thread Function (Procedure)

The Execute method is your thread function. You can think of it as a program that is launched by your application, except that it shares the same process space. Writing the thread function is a little trickier than writing a separate program, because you must make sure that you do not overwrite memory that is used by other processes in your application. On the other hand, because the thread shares the same process space with other threads, you can use the shared memory to communicate between threads.

To implement Execute, coordinate thread execution by

1. Synchronizing with a main VCL thread.
2. Avoiding simultaneous access to the same memory.
3. Waiting for threads.
4. Handling exceptions.

2.5.41 Placing A Bitmap Image in a Control in a VCL Forms Application

This procedure adds a bitmap image to a combo box in a VCL forms application.

1. Create a VCL form.
2. Place components on the form.
3. Set component properties in the Object Inspector.
4. Write event handlers for the component's drawing action.
5. Build and run the application.

To create a VCL form with a TComboBox component

1. Choose **File** ▶ **New** ▶ **Other** ▶ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** is displayed.
2. From the **Win32** page of the **Tool Palette**, place an TImageList component on the form.
3. From the **Standard** page of the **Tool Palette**, place a TComboBox on the form.

To set the component properties

1. Select ComboBox1 in the form.
2. In the **Object Inspector**, set the Style property drop-down to csOwnerDrawFixed.
3. In the **Object Inspector**, click the ellipsis next to the Items property. The **String List Editor** displays.
4. Enter a string you would like to associate with the bitmap image, for example, MyImage; then click **OK**.
5. Double-click ImageList1 in the form. The ImageList editor displays.
6. Click the **Add** button to display the **Add Images** dialog.
7. Locate a bitmap image to display in the Combo box. To locate an image, you can search for *.bmp images on your local drive. Select a very small image such as an icon. Copy it to your project directory, and click **Open**. The image displays in the ImageList editor.
8. Click **OK** to close the editor.

To add the event handler code

1. In the VCL form view, select ComboBox1.
2. In the Object Inspector, click the Events page, and double-click the OnDrawItem event. The **Code Editor** displays with cursor in the code block of the `ComboBox1DrawItem` (Delphi) or `ComboBox1::DrawItem` (C++) event handler.
3. Enter the following code for the event handler:

```
Combobox1.Canvas.FillRect(Rect);
ImageList1.Draw(ComboBox1.Canvas, Rect.Left, Rect.Top, Index);
Combobox1.Canvas.TextOut(Rect.Left+ImageList1.Width+2,
  Rect.Top, ComboBox1.Items[Index]);
```

```
ComboBox1->Canvas->FillRect( Rect );
ImageList1->Draw( ComboBox1->Canvas, Rect.Left, Rect.Top, Index );
ComboBox1->Canvas->TextOut( Rect.Left + ImageList1->Width + 2,
                            Rect.Top,
                            ComboBox1->Items[Index] );
```

To run the program

1. Choose **Run** ▸ **Run**. The applications executes, displaying a form with a combo box.
2. Click the combo box drop-down. The bitmap image and the text string display as a list item.

2.5.42 Reading a String and Writing It To a File

Creating this VCL application consists of the following steps:

1. Create a VCL Form with a button control.
2. Write the code to read the string and write it to a file.
3. Run the application.

To create a VCL Form

1. Create a directory in which to store your project files.
2. Choose **File** ▸ **New** ▸ **Other** ▸ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** is displayed.
3. From the **Standard** page of the Tool palette, place a TButton component on the form.

To read and write a string

1. Select Button1 on the form.
2. In the **Object Inspector**, double-click the OnClick action on the **Events** tab. The **Code Editor** displays, with the cursor in the `TForm1.Button1Click` (Delphi) or `TForm1::Button1Click` (C++) event handler block.
3. For Delphi. place the cursor before the `begin` reserved word; then press return. This creates a new line above the code block.
4. Type the following variable declarations:

```
TFileStream *fs const AnsiString str = "Hello";
```

5. Insert the cursor within the code block, and type the following code:

```
fs = new TFileStream("temp.txt", fmCreate);
 fs->Write ((void*)str.c_str(), str.fmCreate);
```

To run the "Hello world" application

1. Save your project files; then choose **Run** ▸ **Run** to build and run the application. The form displays with a button called **Button1**.
2. Click **Button1**.
3. Use a text editor to open the newly created file temp.txt, which is located in your project directory. The string 'Hello' displays in the file.

VCL Overview (see page 36)

Building a VCL Forms Application (see page 99)

2.5.43 Renaming Files

Creating this VCL application consists of the following steps:

1. Create a project directory containing a file to rename.
2. Create a VCL Form with button and label controls.
3. Write the code to rename the file.
4. Run the application.

To set up your project directory and a text file to copy

1. Create a directory in which to store your project files.
2. Either create or copy a text file to your project directory; then save it as MyFile.txt.

To create a VCL Form with a button and label

1. Choose **File** ▶ **New** ▶ **Other** ▶ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** is displayed.
2. From the **Standard** page of the Tool palette, place a TButton component on the form.
3. From the **Standard** page of the Tool palette, place a TLabel component on the form.

To write the rename file procedure

1. Select Button1 on the form.
2. In the **Object Inspector**, double-click the OnClick action on the **Events** tab. The **Code Editor** displays, with the cursor in the `TForm1.Button1Click` (Delphi) or `TForm1::Button1Click` (C++) event handler block.
3. At the cursor, type the following code:

```
if not RenameFile('MyFile.txt', 'YourFile.txt') then
Label1.Caption := 'Error renaming file!';
if( !RenameFile( "..\\MyFile.txt", "..\\YourFile.txt" )
  Label1->Caption = “Error renaming file”;
// the file parameters assume the target output directory is in your project directory
```

Note: You cannot rename (move) a file across drives using RenameFile. You would need to first copy the file and then delete the old one. In the runtime library, RenameFile is a wrapper around the Windows API MoveFile function, so MoveFile will not work across drives either.

To run the application

1. Save your project file; then choose **Run** ▶ **Run** to build and run the application. The form displays.
2. Click the button; If no message displays in the Label, check the file name in your project directory. MyFile.txt should is renamed as YourFile.txt.
3. If the caption label displays the error message, recheck your event handler code.

VCL Overview (see page 36)

Building a VCL Forms Application (see page 99)

2.5.44 Adding and Sorting Strings

Creating this VCL application consists of the following steps:

1. Create a VCL Form with Button, Label, and TListBox controls.
2. Write the code to add and sort strings.
3. Run the application.

To create a VCL Form with Button, Label, and ListBox controls

1. Choose File ▸ New ▸ Other ▸ Delphi Projects or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** displays.
2. From the **Standard** category of the **Tool Palette**, place a TButton, TLabel, and TListBox component on the form.

To write the copy stream procedure

1. Select Button1 on the form.
2. In the **Object Inspector**, double-click the OnClick action on the **Events** tab. The **Code Editor** displays, with the cursor in the TForm1.Button1Click event handler block.
3. For Delphi, place the cursor before the `begin` reserved word and press ENTER. This creates a new line above the code block.
4. Type the following variable declarations:

```
var
  MyList: TStringList;
  Index: Integer;
TStringList *MyList;
int Index;
```

5. Insert the cursor within the code block, and type the following code:

```
MyList := TStringList.Create;
try
  MyList.Add('Animals');
  MyList.Add('Flowers');

  MyList.Add('Cars');

  MyList.Sort;
    if MyList.Find('Flowers', Index) then
    begin
      ListBox1.Items.AddStrings(MyList);
      Label1.Caption := 'Flowers has an index value of ' + IntToStr(Index);
    end;
finally
    MyList.Free;
end;
MyList = new TStringList();
try {
 MyList->Add( "Animals" );
 MyList->Add( "Flowers" );
 MyList->Add( "Cars" );
 MyList->Sort();
 if( MyList->Find( "Flowers", Index ) {
   ListBox1->Items->AddStrings( MyList );
   Label1->Caption = "Flowers has an index of " +
                     IntToStr( Index );
 }
} __finally {
```

```
 MyList->Free();
}
```

Note: Find will only work on sorted lists. Use IndexOf on unsorted lists.

To run the application

1. Save your project files; then choose **Run** ▸ **Run** to build and run the application. The form displays with the controls.
2. Click the Button. The strings 'Animals', 'Cars', and 'Flowers' display alphabetically in a list in the ListBox. The Label caption displays the message string: 'Flowers has an index value of 2.'

VCL Overview (see page 36)

2.5.45 Creating a VCL Forms ActiveX Button

Like a Delphi control, an ActiveX control generates program code when you place the component on a form or other logical container in the IDE. The main difference between an ActiveX control and a Delphi control is that an ActiveX control is language independent. You can create ActiveX controls for deployment to a variety of programming environments on Windows, not just Delphi or C++Builder.

This procedure uses the VCL forms ActiveX wizard to create an ActiveX control. To test the control, you can install it on your machine as a VCL component in the IDE. To install the control, you first need to create a package for it. This procedure consists of the following major steps:

Metaprocedure for Creating a VCL Forms ActiveX Button

1. Create an ActiveX library project for an ActiveX button control.
2. Register the ActiveX button so its icon can be displayed in the toolbar.
3. Create a package for the ActiveX button.
4. Install the package.
5. Test the ActiveX button.

To create an ActiveX library project for an ActiveX button control

1. Create a directory on your local drive for the ActiveX project. Give it a name that you can find easily, for example, ActiveX.
2. Choose **File** ▸ **New** ▸ **Other** and select the **ActiveX** page in the **New Items** dialog box.
3. In the **ActiveX** folder, double-click **ActiveX Library**. This creates a Dynamic Link Library [DLL] project that you can use to host in-process ActiveX Objects.
4. Choose **File** ▸ **New** ▸ **Other** again.
5. On the **ActiveX** page, double-click **ActiveX Control**. The **ActiveX Control Wizard** displays.
6. In the **Component Name** drop-down, select **TButton**.
7. By default, **ButtonX** displays as the **New ActiveX Name**. Rename ButtonX to the name you want displayed for your ActiveX button, for example, MyActiveXButton.

   Note: Modifications you make to the name update the Implementation Unit and Project Name. Leave the remaining fields with default values.

8. Click **OK**. The wizard generates the code needed to implement the ActiveX control and adds the code to the project. If the project is already an ActiveX library, the wizard adds the control to the current project.

Note: If the project is not already an ActiveX library, a Warning

dialog displays and asks you if you want to start a new ActiveX library project.

9. Click **OK** to start the new ActiveX Library project.

To register the ActiveX button

1. Build the project and save all files to your ActiveX project directory. Dismiss the warning about debugging. The project builds and creates an OCX file in your project directory.
2. Choose **Run** ▶ **Register ActiveX Server** to register the ActiveX button. A dialog box displays a message indicating that registration was successful and it shows the path to the resulting OCX file.
3. Click **OK**.

To create a new package for the ActiveX button

1. Choose **File** ▶ **New** ▶ **Other** to create a new package. The **New Items** dialog displays.
2. Double-click Package on the **New** page to display the **Package - package.dpk** dialog and click **Add**.
3. On the **Add unit** tab of the **Add** dialog, browse to your project directory.
4. Select the `ButtonXControl1_TLB.pas` file, and click **Open**.
5. Click **OK** to add the file to the package and return to the **Package - package.dpk** dialog. The **Package - package.dpk** dialog displays showing the files in the package and two required files: rtl.dcp and vcl.dcp.

To add the required files and install the package

1. In the **Package - package.dpk** dialog, select rtl.dcp, and click **Add**.
2. On the **Add unit** tab of the **Add** dialog, browse to the Lib directory in Delphi, select the rtl.dcp file, and click **Open**; then click **OK** on the **Add** dialog.
3. In the **Package - package.dpk** dialog, select vcl.dcp, and click **Add**.
4. On the **Add unit** tab of the **Add** dialog, browse to the Lib directory in Delphi, select the vcl.dcp file, and click **Open**; then click **OK** on the **Add** dialog.
5. In the **Package - package.dpk** dialog, click **Compile** to compile the package. A dialog displays, indicating that the package has been installed. Click **OK**.
6. Click the X in the upper right corner of the **Package - package.dpk** dialog to close it. You are prompted to save the package.
7. Save the package to your projects directory.

To test the button

1. Choose **File** ▶ **New Application**.
2. From the **ActiveX** page of the **Tool Palette**, locate your button and place it on the form. The button displays on the form.

VCL Overview (see page 36)

Creating a VCL Forms ActiveX Active Form (see page 140)

2.5.46 Creating a VCL Forms ActiveX Active Form

Like a Delphi control, an ActiveX control generates program code when you place the component on a form or other logical container in the IDE. The main difference between an ActiveX control and a Delphi control is that an ActiveX control is language independent. You can create ActiveX controls for deployment to a variety of programming environments on Windows, not just

Delphi or C++Builder, for example.

This procedure uses the VCL forms ActiveX Active Form wizard to create an Active Form containing two components. To test the control, you can deploy it to the Web. This procedure consists of the following major steps:

1. Create an ActiveX library project for an ActiveX Active Form.
2. Add controls to the Active Form.
3. Add event handling code for the controls.
4. Deploy the project to the Web.
5. Display the form and test the controls in your Web browser.

To create an Active X library project for an ActiveX Active Form

1. Create a directory on your local drive for the ActiveX project. Give it an easy to find name, for example, ActiveX.
2. Create a second directory to contain the ActiveX component and an HTML file for deploying the Active Form to your Microsoft Internet Explorer Web browser. Name this directory ActiveX_Deploy.
3. Choose **File** ▸ **New** ▸ **Other** and select the **ActiveX** page in the **New Items** dialog.
4. On the **ActiveX** page, double-click Active Form. The **Active Form Wizard** displays.
5. Accept the default settings and click **OK**. The wizard generates the code needed to implement the ActiveX control and adds the code to the project. If the project is already an ActiveX library, the wizard adds the control to the current project.

   Note: If the project is not already an ActiveX library, a Warning

   dialog displays and asks you if you want to start a new ActiveX library project.
6. Click **OK** to start a new ActiveX library project. An ActiveX Active Form displays.

To add some functionality to the Active Form

1. From the **Standard** page of the **Tool Palette**, add TEdit and TButton components to the form.
2. Select the button.
3. On the **Events** tab in the **Object Inspector**, double-click the OnClick event. The **Code Editor** opens with the cursor in place in the `TActiveFormX.Button1Click` (Delphi) or `TActiveFormX::Button1Click()` (C++) event handler block. Enter the following code at the cursor:

```
ShowMessage(Edit1.text);
ShowMessage( Edit1->Text )
```

4. Save the project files to your ActiveX directory.

   Note: To deploy the Active form to your Web, use the Deployment Manager

   . Click **File** ▸ **New** ▸ **Other** ▸ **Deployment**.

To test the Active Form

1. Launch your browser.
2. Choose **File** ▸ **Open**, and browse to the ActiveX_Deploy directory.
3. Double-click the HTML file to launch it in the browser window. The Active Form displays in the browser window.
4. Click the button. A pop-up dialog displays the text in the Edit box.
5. Change the text, and click the button again. The new text you entered displays in the pop-up.

VCL Overview (see page 36)

Creating a VCL Forms ActiveX Button (see page 139)

2.5.47 Building a VCL Forms Web Browser Application

Creating the Web browser application consists of the following steps:

1. Create a VCL Form with a button control.
2. Add a TWebBrowser component to the form.
3. Add controls to enter a URL and launch the browser.
4. Write the code to launch the browser when a button is clicked.
5. Run the application.

To create a VCL Form

1. Choose **File** ▶ **New** ▶ **Other** ▶ **Delphi Projects** or C++Builder Projects and double-click the **VCL Forms Application** icon. The **VCL Forms Designer** is displayed.
2. From the **Internet** page of the **Tool Palette**, place a TWebBrowser component on the form.
3. With the TWebBrowser component selected on the form, drag the handles to adjust the size of the browser window. Leave some space on the form above the TWebBrowser to add a URL entry window. If the window is not large enough to display a browser page in its entirety, the TWebBrowser component adds scrollbars when you run the application and launch the browser window.
4. From the **Standard** page of the **Tool Palette**, place a TMemo component on the form. With the TMemo component selected on the form, drag the handles to adjust the size to accommodate a user-entered URL.
5. From the **Standard** page of the **Tool Palette**, place a Label component on the form.
6. Select the Label, and in the **Object Inspector**, enter URL: as the Label caption.
7. From the **Standard** page of the **Tool Palette**, place a TButton component on the form.
8. Select the Button, and in the **Object Inspector**, enter OK as the TButton caption.

To code a button click event that launches the browser

1. Select Button1 on the form.
2. In the **Object Inspector**, double-click the OnClick action on the **Events** tab. The **Code Editor** displays, with the cursor in the Button1Click event handler block.
3. Type the following code:

```
WebBrowser1.Navigate(WideString(Memo1.Text));
WebBrowser1->Navigate( WideString( Memo1->Text ) );
```

To run the application

1. Choose **Run** ▶ **Run** to build and run the application.
2. Enter a URL to a Web page in the memo window; then click the button. The browser launches in the TWebBrowser window.

VCL Overview (see page 36)

Building a VCL Forms Application (see page 99)

2.5.48 Creating an Application that Uses Ribbon Controls

This procedure describes how to create an application that uses ribbon controls. The core ribbon functionality is derived from the TRibbon component. While the ribbon uses other components, none of the core components are registered on the tool palette.

Components:

1. **TRibbon:** Main visual component that provides most functionality.
2. **TRibbonApplicationMenuBar:** Component that provides the functionality of the application menu.
3. **TRibbonQuickAccessToolbar:** Component that provides the functionality of the Quick Access Toolbar
4. **TRibbonPage:** Component that represents the page of the ribbon that is currently visible
5. **TRibbonGroup:** Component that all of the pages commands are displayed in. Commands must be placed in a group.

To create a new application that uses ribbon controls

1. Create a new Delphi Win32 VCL application (select **New ▸ VCL Forms Application — Delphi for Win32**).
2. Drop a TActionManager component onto the form.
3. Drop a TRibbon component onto the form.
4. Right-click the TRibbon component and select the **Add Application Menu** item.
5. Right-click the TRibbon component again and select the **Add Quick Access Toolbar** item.

   Note: During initial configuring of the ribbon you might see a dialog saying that the current style selected in the TActionManager.Style is not a valid ribbon style. Change the TRibbonManager.Style property to be the **Ribbon – Luna**. Applicable styles for use with the ribbon have the Ribbon prefix. By default three ribbon styles are implemented. These ribbon styles also work with the default ActionManager toolbar and menu bar controls. The available ribbon Styles are:

- Luna
- Obsidian
- Silver

2.5.49 Adding Commands to the Ribbon

This topic follows in sequence the creation of a ribbon application using either the Ribbon Application Wizard or the manual steps described in Creating an Application that Uses Ribbon Controls (see page 143).

This topic assumes that you are familiar with the TActionManager component and the components associated with its use. Numerous new properties have been added to help support the ribbon requirements. Many existing properties have no effect when modified on a command that is displayed on the ribbon.

For instance:

- Small buttons always display their glyph to the left of the caption.
- Large buttons always display their glyph at the top.
- A Large button must have a caption. The caption can be a maximum of two lines, and the button width is resized accordingly. A large button's height is fixed to cover the height of the group where the command is displayed.
- Only small buttons with no caption can be displayed in groups.

New Properties

CommandStyle: The CommandStyle determines the type of control that is used to represent this command on the ribbon. The default style is **csButton**. CommandStyle is used extensively for determining the control type that is used for the command except under one exception.

```
type TCommandStyle = (csButton, csMenu, csSeparator, csText, csGallery, csComboBox, csControl, csCustom);
```

Style of the Command on the Ribbon Group

csButton	Command is a button.
csComboBox	Command displays an Office 2007 style combobox. See following Note.
csControl	Command has a TControl descendant associated with it. An example is dropping a TEdit component onto a ribbon Group.
csCustom	User-defined.
csGallery	Command is a gallery or when selected, it displays a gallery.
csMenu	Command is a menu item
csSeparator	Command is a separator with a text description.
csText	Command only displays text and has no associated control.

Note: You can only use the csComboBox CommandStyle if you first place a TRibbonComboBox from the tool palette onto your ribbon Group.

CommandProperties: CommandProperties is a dynamic property class. The published properties of this property (it is a TPersistent descendant) vary depending on the CommandStyle that has been selected. If you select the **csButton** CommandStyle, the CommandProperties class used is called TButtonProperties. This property class publishes properties that are specific to the csButton CommandStyle.

An example is ButtonSize, which allows you to indicate if the button is a large button or a small button. There is no need for a csMenu command to have a ButtonSize property because the menu does not react to a size variance.

All CommandProperties classes descend from **TCommandProperties**. If you are using the csCustom CommandStyle, you must descend from the TCommandProperties class.

Properties that can be available in the CommandProperties property depending on your selected CommandStyle

csButton	ButtonSize
	Size of the button:
	TButtonSize = (bsSmall, bsLarge);
	ButtonType
	Special types of buttons allowed:
	TButtonType = (btNone, btDropDown, btSplit, btGallery); // btNone - normal button // btDropdown - button display a dropdown menu // btSplit - button has dropdown menu and a default action // btGallery - button displays a gallery as a dropdown
	GroupPosition
	Position of this command in a group of commands:
	TGroupPosition = (gpNone, gpStart, gpMiddle, gpEnd, gpSingle); // Determines whether a border is drawn around a button // gpNone - no border drawn // gpStart - the right edge of a border isn't drawn // gpMiddle - top and bottom of border is drawn // gpEnd - the left edge isn't drawn // gpSingle - the full border is drawn

csCheckBox	Command appears like an Office 2007 checkbox.

csComboBox	AllowResize Controls whether the popup menu associated with the combo box can be resized:
	TGalleryResize = (grNone, grVertical, grBoth); // grNone – don't allow resizing // grVertical – only allow vertical resizing // grBoth – allow both vertical and horizontal resizing
	Items
	Items to display when the user selects the dropdown button. These items display in a window like a regular combobox.
	Text
	The text to display in the combobox.
	Width
	The width of the spinner control, excluding any caption width.

csControl	ContainedControl Reference to the control it is associated with on the ribbon.
csCustom	User-defined.

csGallery	The csGallery CommandProperties class descends from the csButton CommandProperties class. This means all of the csButton properties are also available for csGallery commands, as well as the following gallery ones.
	GalleryType
	Type of gallery to be displayed:
	TGalleryType = (gtDropDown, gtGrid, gtRibbon); // gtDropDown - Gallery is in the form of a dropdown menu // gtGrid - Gallery is a grid layout. Meaning it can be more than one item across. ItemsPerRow controls the number of items across // gtRibbon - Gallery is in Ribbon
	ItemsPerRow
	Number of items to display on a row.
	ShowRichContent
	Set to true to display rich content for the gallery items.

csMenu	ShowRichContent: Set to true to display rich content for the menu item. Content: The content to be displayed as rich content. Font: Use a custom font when displaying the rich content. Rich content menu items are limited to two lines. Depending on the content, the menu items might be wider and are not changed to be taller, and some menu items therefore display additional lines (beyond the two permitted.)
csRadioButton	Command appears like an Office 2007 radio button.

csSeparator	csText and csSeparator share the same CommandProps class, so the available properties are the same. Alignment: The alignment of the caption text. EllipsisPosition: Position of any ellipsis if caption text is too wide for the menu width. It is only possible for menu items to be displayed in the Application menu. Font: Font to use when drawing the caption text. Width: Force the width of the created control to be a specific size. Leave as -1 for csSeparator CommandStyle and modify as required for csText CommandStyle.
csText	csText and csSeparator share the same CommandProps class, so the available properties are the same.

Additional Ribbon Component Properties

KeyTip: The key that can be pressed to activate the command when using the keyboard. To activate KeyTips, press either the Alt or F10 key.

NewCol: Setting NewCol for a command forces the control to be displayed in a new column of the ribbon group. This property is only effective when the ribbon group alignment is gaVertical.

NewRow: Setting NewRow for a command forces the control to be displayed in a new row of the ribbon group. This property is only effective when the ribbon group alignment is gaHorizontal.

Default: Set to true to force a menu items caption to be bolded. Only effective for menu items.

2.6 WebSnap Procedures

This section provides how-to information on developing WebSnap applications.

Please note that WebSnap is being deprecated in RAD Studio. Although WebSnap is still documented in the online help, the WebSnap product is no longer fully supported. As an alternative, you should begin using IntraWeb (VCL for the Web). IntraWeb (see page 2254) is documented in this online help. For more documentation on VCL for the Web, go to http://www.atozed.com/intraweb/docs/.

Topics

Name	Description
Building a WebSnap Application (see page 148)	The following procedure describes the generic steps required to build a simple WebSnap project. For more advanced topics, refer to related information following the procedure. Building a WebSnap application consists of five major steps: 1. Create an WebSnap project. 2. Change included components (optional). 3. Set page options (optional) 4. Create additional WebSnap pages. 5. Run the application. **Note:** WebSnap is being deprecated in RAD Studio. Although WebSnap is still documented in the online help, the WebSnap product is no longer fully supported. As an alternative, you should begin using IntraWeb (VCL for the Web). IntraWeb (see page 2254) is documented in this online help. For more documentation... more (see page 148)
Building a WebSnap "Hello World" Application (see page 149)	Though simple, the WebSnap "Hello world" application demonstrates the essential steps for creating an WebSnap application. Building the WebSnap "Hello world" application consists of five major steps: 1. Create a WebSnap project. 2. Accept the default included components. 3. Set the page title in the page options. 4. Modify the HTML template. 5. Run the application.
Debugging a WebSnap Application using the Web Application Debugger (see page 150)	This topic describes the essential tasks for debugging a WebSnap application using the Web Application Debugger.
Using the HTML Tag Editor (see page 151)	When you are creating or editing an HTML file, you can use the **Tag Editor** window, beneath the Form Designer, to edit the HTML tags. If you are using an HTML Form, you can display the Tag Editor in the Designer by selecting **View ▶ Tag Editor**. The **Tag Editor** lets you review and modify HTML tags while viewing the corresponding controls in the Designer window, above it. The **Tag Editor** allows you to use the **Code Completion**, **Error Insight**, and **Live Template Completion** features that are also available in the **Code Editor**. Refer to the links... more (see page 151)

2.6.1 Building a WebSnap Application

The following procedure describes the generic steps required to build a simple WebSnap project. For more advanced topics, refer to related information following the procedure.

Building a WebSnap application consists of five major steps:

1. Create an WebSnap project.
2. Change included components (optional).
3. Set page options (optional)
4. Create additional WebSnap pages.
5. Run the application.

Note: WebSnap is being deprecated in RAD Studio. Although WebSnap is still documented in the online help, the WebSnap product is no longer fully supported. As an alternative, you should begin using IntraWeb (VCL for the Web). IntraWeb (see page 2254) is documented in this online help. For more documentation on VCL for the Web, go to http://www.atozed.com/intraweb/docs/.

To create a WebSnap project

1. Choose **File** ▸ **New** ▸ **Other**. The **New Items** dialog appears.
2. In the **New Items** dialog, select **WebSnap Application** from the **Delphi Projects** ▸ **WebSnap** folder.
3. Click **OK**. The **New WebSnap Application** dialog appears.
4. Select the type of application you are creating.
5. Select your application model components.
6. In the **Page Name** field, enter the name of your page.
7. Select your caching type from the **Caching** drop-down.

To change included components (optional)

1. In the **New WebSnap Application** dialog, click **Components**. The **WebApp Components** dialog appears.
2. Select the components you want to include.

   Tip: In most cases, the default settings will suffice.

3. Click **OK**.

To set page options (optional)

1. In the **New WebSnap Application** dialog, click **Page Options**. The **WebApp Components** dialog appears.
2. Set the page options.

To create additional WebSnap pages

1. In the **New Items** dialog, select **WebSnap Page Module** from the **Delphi Projects** ▸ **WebSnap** folder.
2. Configure the page module options and click **OK**.
3. Add and configure components.

Web Applications Overview (see page 41)

Building an WebSnap "Hello world" Application (see page 149)

2.6.2 Building a WebSnap "Hello World" Application

Though simple, the WebSnap "Hello world" application demonstrates the essential steps for creating an WebSnap application.

Building the WebSnap "Hello world" application consists of five major steps:

1. Create a WebSnap project.
2. Accept the default included components.
3. Set the page title in the page options.
4. Modify the HTML template.
5. Run the application.

To create a WebSnap project

1. Choose **File** ▶ **New** ▶ **Other**. The **New Items** dialog appears.
2. In the **New Items** dialog, select **WebSnap Application** from the **Delphi Projects** ▶ **WebSnap** or **C++Builder Projects** ▶ **WebSnap** folder.
3. Click **OK**. The **New WebSnap Application** dialog appears.
4. Select the **Web App Debugger executable** radio button.
5. In the **Class Name** field, enter `HelloWorld`.
6. Select your application model components.
7. In the **Page Name** field, enter `HelloWorld`.
8. Select your caching type from the **Caching** drop-down.

To change included components (optional)

1. In the **New WebSnap Application** dialog, click **Components**. The **WebApp Components** dialog appears.
2. Select the components you want to include.

   Tip: In most cases, the default settings will suffice.

3. Click **OK**.

To set the page title in the page options

1. In the **New WebSnap Application** dialog, click **Page Options**. The **WebApp Components** dialog appears.
2. In the **Title** field, enter `Hello World!`.

To modify the HTML template

1. Click on the HTML tab in the IDE.
2. Below the line `<h2><%= Page.Title %></h2>`, insert a line saying `This is my first WebSnap application.`
3. Save the application.

To run the "Hello world" application

1. Choose **Run** ▶ **Run**. An application window opens, and the COM server registers your WebSnap application with the Web Application Debugger.

2. Close the application window.
3. Choose **Tools** ▸ **Web App Debugger** . The Web Application Debugger launches.
4. In the Web App Debugger, click the **Start** button.
5. Click on the **Default URL** to launch the browser.
6. In the browser, select your Hello World application from the list of applications and click **Go**. Your application appears in the browser with the text `Hello World! This is my first WebSnap application.`
7. Close the Web browser to return to the IDE.

Note: WebSnap is being deprecated in RAD Studio. Although WebSnap is still documented in the online help, the WebSnap product is no longer fully supported. As an alternative, you should begin using IntraWeb (VCL for the Web). IntraWeb (see page 2254) is documented in this online help. For more documentation on VCL for the Web, go to http://www.atozed.com/intraweb/docs/.

2.6.3 Debugging a WebSnap Application using the Web Application Debugger

This topic describes the essential tasks for debugging a WebSnap application using the Web Application Debugger.

To debug a WebSnap Application using the Web Application Debugger

1. Register the server information application for the Web Application Debugger.
2. Register your WebSnap application with the Web Application Debugger the first time you run it.
3. Launch the Web Application Debugger.
4. Select and launch your web application.
5. Debug your web application using breakpoints and the Web Application Debugger log.

To register the server information application for the Web Application Debugger

1. Navigate to the `bin` directory of your RAD Studio installation.
2. Run `serverinfo.exe`.
3. Close the blank application window that opens.

This step only needs to be performed the first time you use the Web Application Debugger.

To register your web application with the Debugger

1. Choose **Run** ▸ **Run**. This displays the console window of the COM server that is your Web server application.
2. Close the blank application window that opens.

Your COM server is now registered so that the Web App debugger can access it.

To launch the Web Application Debugger

1. Choose **Tools** ▸ **Web App Debugger** . The Web Application Debugger launches.
2. In the Web App Debugger, click the **Start** button.
3. Click on the **Default URL** to launch the browser.

To select and launch your web application

1. In the browser, select your application from the list of applications.
2. Click **Go**. Your application appears in the browser.

   Note: WebSnap is being deprecated in RAD Studio. Although WebSnap is still documented in the online help, the WebSnap product is no longer fully supported. As an alternative, you should begin using IntraWeb (VCL for the Web). IntraWeb (see page 2254) is documented in this online help. For more documentation on VCL for the Web, go to http://www.atozed.com/intraweb/docs/.

Web Applications Overview (see page 41)

Building an WebSnap Application (see page 148)

2.6.4 Using the HTML Tag Editor

When you are creating or editing an HTML file, you can use the **Tag Editor** window, beneath the Form Designer, to edit the HTML tags. If you are using an HTML Form, you can display the Tag Editor in the Designer by selecting **View** ▸ **Tag Editor**.

The **Tag Editor** lets you review and modify HTML tags while viewing the corresponding controls in the Designer window, above it. The **Tag Editor** allows you to use the **Code Completion**, **Error Insight**, and **Live Template Completion** features that are also available in the **Code Editor**. Refer to the links at the end of this topic for more information about using each of these features.

The **Tag Editor** works with one tag at a time, unless you have the Document object selected or you have zoomed out from a tag. (When the document object is selected, you'll see the item "DOCUMENT" on the Object Inspector.)

Use the zoom buttons to zoom out to a tag's parent and zoom back in to the selected child tag. Zooming isn't specific to the tag, it's more generic to the markup in the document itself. For example, if the cursor is on a tag in your HTML markup, and you use the Zoom command, it will take you to the outer tag, or one level above the attribute where the cursor is positioned.

Validation against standard HTML style rules occurs automatically. If validation fails, the incorrect element is highlighted in red in the **Designer**, and **Error Insight** appears in the **Tag Editor** to help you correct the problem.

To view HTML code for an individual control

1. With the Designer displayed, drag an HTML element from the **Tool Palette** to the Designer surface. The **Tag Editor** displays the HTML code.
2. To view the individual control's code, click anywhere on the Designer surface to deselect the control. The HTML code appears in the tag editor window, with syntax highlighting. The gray header of the tag editor now displays the higher level tag, usually the FORM tag that defines this particular Web Form.

   Note: If a control is defined using several lines of HTML code, when you select the control, the first line of the code is displayed in the gray header of the tag editor. The additional code appears below in the tag editor window.

To view the HTML code for all controls

1. With the Designer displayed, drag several HTML elements from the **Tool Palette** to the Designer surface. The editor displays the HTML code for each element as you drop them on the Designer surface.
2. Click anywhere on the Designer surface to deselect all controls. This displays the code for all the controls in the tag editor, with syntax highlighting.

To modify a control

1. Click anywhere on the Designer surface to deselect all controls.
2. Locate the tag that corresponds to the control you want to modify.
3. Modify the code, and the change is immediately reflected in the control on the Designer surface.
4. Save your project to make the modifications permanent.

To change editor properties

1. Choose **Tools** ▸ **Options** ▸ **HTMLOptions**.
2. Change any code editor properties.
3. Click **OK**. Your changes take effect immediately.

To zoom between contents of the form and the form container

1. To zoom out so that you can view the HTML form definition, click the left-hand blue arrow in the gray header of the tag editor.

   Note: You can only use this feature when the cursor is somewhere in the tag editor, rather than on the Designer surface.

2. To zoom in so that you can view only the content within the FORM tags, click the right-hand blue arrow in the gray header of the tag editor.

   Note: You can only use this feature when the cursor is somewhere in the tag editor, rather than on the Designer surface.

To close the Tag Editor

1. Choose **Tools** ▸ **Options** ▸ **HTML Options**.
2. Uncheck the **Display Tag Editor** option.
3. Click **OK**.

2.7 Web Services Procedure

This section provides how-to information on developing and using web services.

Topics

Name	Description
Building a "Hello World" Web Services Application (see page 153)	Web Services are self-contained modular applications that can be published and invoked over a network (such as the World Wide Web). Web Services use SOAP, a standard lightweight protocol for exchanging information in a distributed environment. It uses HTTP as a communications protocol and XML to encode remote procedure calls.

2.7.1 Building a "Hello World" Web Services Application

Web Services are self-contained modular applications that can be published and invoked over a network (such as the World Wide Web). Web Services use SOAP, a standard lightweight protocol for exchanging information in a distributed environment. It uses HTTP as a communications protocol and XML to encode remote procedure calls.

To build a "Hello World" Web Services application

1. Choose **File** ▶ **New** ▶ **Other**. The **New Items** dialog box appears.
2. Select **WebServices** folder.
3. Double-click the **Soap Server Application** icon. The **SOAP Server Application** wizard opens.
4. Choose the type of Web server application you want to use for your Web Service. The wizard generates a new Web server application that includes a Web module that contains three components—HTTPSoapPascalInvoker, HTTPSoapDispatcher, and WSDLHTMLPublish. When you exit the SOAP Server Application wizard, it asks you if you want to define an interface for your Web Service.
5. To create a a Web Service from scratch, click **Yes**. The **Add New Web Service** wizard opens.
6. To add a new Web Service, specify the name of the invokable interface you want to expose to clients. The **Add New Web Service** wizard lets you specify the name of the invokable interface and generates the code to declare and register the interface and its implementation class.
7. To implement a Web Service that has already been defined in a WSDL document, use the WSDL importer to generate the interfaces

To use the WSDL importer

1. Choose **File** ▶ **New** ▶ **Other**. A **New Items** dialog appears.
2. Select **WebServices** folder.
3. Double-click the icon labeled **WSDL importer**. A **WSDL Import Wizard** appears.
4. In that dialog box, either specify the file name of a WSDL document (or XML file) or click the ellipsis button [...] to browse for the file.
5. If the WSDL document is on a server that requires authentication, click **Options**. On the **Import Options** dialog box, enter the user name and password required before the wizard can retrieve the WSDL document. After completing the import options, click **OK**.
6. Click **Next**. The WSDL importer displays the code it generates for every definition in the WSDL document that is compatible with the Web Services framework.

7. Click **Finish**. The importer creates new units that define and register invokable interfaces for the operations defined in the document, and that define and register remotable classes for the types that the document defines.

3 Reference

Topics

Name	Description
C++ Reference (see page 156)	This section contains reference topics for the C++ library in RAD Studio.
Win32 Developer's Guide (see page 1217)	This section contains the Win32 Developer's Guide topics for the Delphi Win32 personality in RAD Studio.

3.1 C++ Reference

This section contains reference topics for the C++ library in RAD Studio.

Topics

Name	Description
Command Line Utilities (see page 156)	C++Builder provides a rich set of command line utilities in addition to its integrated development environment (IDE). These utilities enable you to use the command line to perform targeted compilation and other related functions, including file search and import of definition files.
C++ Compiler Errors And Warnings (C++) (see page 216)	This section describes the RAD Studio C++ compiler error and warning messages.
C++ Language Guide (see page 385)	This sections contains C++ language topics.
C Runtime Library Reference (see page 711)	RAD Studio has several hundred functions, macros, and classes that you call from within your C and C++ programs to perform a wide variety of tasks, including low- and high-level I/O, string and file manipulation, memory allocation, process control, data conversion, mathematical calculations, and more. **Note:** In the online help, each function, macro, and class in the C Runtime Library is listed only once . However, some functions, macros, and classes are defined in more than one header file. For example, `_strerror` is defined in both string.h and stdio.h. For functions that are defined in several header files, the online... more (see page 711)

3.1.1 Command Line Utilities

C++Builder provides a rich set of command line utilities in addition to its integrated development environment (IDE). These utilities enable you to use the command line to perform targeted compilation and other related functions, including file search and import of definition files.

Topics

Name	Description
BCC32, the C++ Command-Line Compiler (see page 159)	The CodeGear C++ compiler (BCC32.EXE) is a resource compiler shell. It invokes BRCC32 and RLINK32, depending on the command-line syntax.
BRC32, the Resource Shell (see page 163)	The Borland resource compiler (BRC32) is a resource compiler shell. It invokes BRCC32 and RLINK32, depending on the command-line syntax.
BRCC32.EXE, the Resource Compiler (see page 165)	BRCC32 is the command-line version of the resource compiler. It accepts a resource script file (.RC) as input and produces a resource object file (.RES) as output. RAD Studio provides a choice in resource compilers. You can choose to use either BRCC32 or RC (the Microsoft SDK resource compiler) on the **Project** ▶ **Options** ▶ **Resource Compiler** dialog box.
COFF2OMF.EXE, the Import Library Conversion Tool (see page 166)	COFF2OMF converts a COFF import library file (InputFile) to a corresponding OMF import library file (OutputFile). COFF2OMF.EXE is located in the C++Builder \bin directory.
CPP32.EXE, the C Compiler Preprocessor (see page 167)	CPP32.EXE produces a file that lists a C or C++ program, in which all #include files and #define macros have been expanded. While you do not need to use the preprocessor during normal compilation, you may find the list file helpful for debugging purposes. Often, when the compiler reports an error inside a macro or an include file, you can get more information about what the error is if you can see the include files or the results of the macro expansions. In many multi-pass compilers, a separate pass performs this work, and the results of the pass can be... more (see page 167)
DCC32.EXE, the Delphi Command Line Compiler (see page 169)	DCC32 is the Delphi (Object Pascal) command line compiler. To display command line help, enter:

GREP.EXE, the text search utility (see page 170)	GREP (Global Regular Expression Print) is a powerful text-search program derived from the UNIX utility of the same name. GREP searches for a text pattern in one or more files or in its standard input stream.
ILINK32.EXE, the Incremental Linker (see page 174)	ILINK32 links object modules (.OBJ files), library modules (.LIB files), and resources to produce executable files (.EXE, .DLL, and .BPL files). ILINK32 creates and maintains a series of state files that contains this information. These state files allow subsequent links to be incremental, greatly reducing the total link time.
IMPDEF.EXE, the Module Definition Manager (see page 179)	Import libraries provide access to the functions in a Windows DLL. Import libraries contain records. Each record contains the name of a DLL and specifies where in the DLL the imported functions reside. These records are bound to the application by the linker and provide Windows with the information necessary to resolve DLL function calls. You can substitute an import library for part or all of the IMPORTS section of a module definition file. IMPDEF takes as input a DLL name, and produces as output a module definition file with an EXPORTS section containing the names of functions exported by... more (see page 179)
IMPLIB.EXE, the Import Library Tool (see page 181)	IMPLIB takes as input either DLLs or module definition files, or both, and produces an import library as output. If you've created a Windows application, you've already used IMPORT32.LIB, the import library for the standard Windows DLLs. IMPORT32.LIB is linked automatically when you build a Win32 application in the C++Builder IDE and when using BCC32 at the command line. An import library lists some or all of the exported functions for one or more DLLs. IMPLIB creates an import library directly from DLLs or from module definition files for DLLs (or a combination of the two).
Using Include Files (see page 182)	In C++, include files always have the file extension .h.
MAKE (see page 183)	MAKE.EXE is a command-line utility that helps you manage project compilation and link cycles. MAKE is not inherently tied to compiling and linking, but is a more generic tool for executing commands based on file dependencies. MAKE helps you quickly build projects by compiling only the files you have modified since the last compilation. In addition, you can set up rules that specify how MAKE should deal with the special circumstances in your builds.
MAKE Directives (see page 186)	MAKE directives resemble directives in languages such as C and Pascal. In MAKE, directives perform various control functions, such as displaying commands onscreen before executing them. MAKE directives begin either with an exclamation point or a period, and they override any options given on the command line. Directives that begin with an exclamation point must appear at the start of a new line. The following table lists the MAKE directives and their corresponding command-line options:
MAKE Macros (see page 191)	A macro is a variable that MAKE expands into a string whenever MAKE encounters the macro in a makefile. For example, you can define a macro called LIBNAME that represents the string "mylib.lib." To do this, type the line LIBNAME = mylib.lib at the beginning of your makefile. Then, when MAKE encounters the macro $(LIBNAME), it substitutes the string mylib.lib. Macros let you create template makefiles that you can change to suit different projects. To use a macro in a makefile, type $(MacroName) where MacroName is a defined macro. You can use either braces or parentheses to enclose MacroName. MAKE... more (see page 191)
MAKE Rules (Explicit and Implicit) and Commands (see page 193)	You write explicit and implicit rules to instruct MAKE how to build the targets in your makefile. In general, these rules are defined as follows: • Explicit rules are instructions for specific files. • Implicit rules are general instructions for files without explicit rules. All the rules you write follow this general format:
Message Options (see page 197)	Use the -w option to specify message options for the CodeGear C++ compiler: • To enable a particular warning message, enter the -w option with a one- to three-letter option code. • To disable the warning message, enter the -w- option with a one- to three- letter option code.

Module Definition Files (see page 199)	You use module definition files with ILINK32. A module definition file is an ASCII text file that provides information to ILINK32 about the contents and system requirements of a Windows application. Use IMPDEF to create a module definition file. The module definition file names the .EXE or .DLL, identifies the application type, lists imported and exported functions, describes the code section and data segment attributes, lets you specify attributes for additional code sections and data segments, specifies the size of the stack, and provides for the inclusion of a stub program.
Using Precompiled Header Files (see page 203)	Precompiled header files can dramatically increase compilation speed by storing an image of the symbol table on disk in a file, then later reloading that file from disk instead of parsing all the header files again. Directly loading the symbol table from disk is much faster than parsing the text of header files, especially if several source files include the same header file. To use precompiled header files, specify the various -H options in your BCC32 command. ***Precompiled Header Options***
RLINK32.DLL, the Resource Linker (C++) (see page 204)	RLINK32.DLL is the resource linker that binds resources, in .RES file form, to an .EXE file, and marks the resulting .EXE file as a Windows executable. RLINK32.DLL also: • Links the resources by fixing up string tables and message tables and then binding these linked resources into the executable. • Is called by ILINK32 and is used for 32-bit resources.
TDUMP.EXE, the File Dumping Utility (see page 204)	TDUMP.EXE produces a file dump that shows the structure of a file. TDUMP breaks apart a file structurally and uses the file's extension to determine the output display format. TDUMP recognizes many file formats, including .EXE, .OBJ, and .LIB files. If TDUMP doesn't recognize an extension, it produces a hexadecimal dump of the file. You can control the output format by using the TDUMP command-line options when you start the program. TDUMP's ability to peek at a file's inner structure displays not only a file's contents, but also how a file is constructed. Moreover, because TDUMP verifies that a file's... more (see page 204)
TLIB.EXE, the Library Manager (see page 208)	TLIB is a utility that manages libraries of .OBJ (object module) files. A library is a convenient way to deal with a collection of object modules as a unit. The libraries included with the CodeGear C++ compiler were built with TLIB. You can use TLIB to build your own libraries, or to modify the CodeGear C++ libraries, your libraries, libraries furnished by other programmers, or commercial libraries you've purchased. When TLIB modifies an existing library, TLIB creates a copy of the original library and gives it a .BAK extension. You can use TLIB to: • Create a new library from a... more (see page 208)
Using TOUCH.EXE (see page 212)	TOUCH.EXE updates a file's date stamp so that it reflects your system's current time and date.
TRIGRAPH (see page 213)	Trigraphs are three-character sequences that replace certain characters used in the C language that are not available on some keyboards. Translating trigraphs in the compiler would slow compilation down considerably, so CodeGear C++ provides a filter named TRIGRAPH.EXE to handle trigraph sequences.
RC.EXE, the Microsoft SDK Resource Compiler (see page 213)	RC is the command-line version of the standard Microsoft SDK resource compiler. It accepts a resource script file (.RC) as input and produces a resource object file (.RES) as output. Both C++Builder 2009 and Delphi 2009 give you a choice of resource compilers. On the **Project** ▶ **Options** ▶ **Resource Compiler** dialog box, you can select either of the following: • BRCC32.exe, the CodeGear resource compiler • RC.exe, the Microsoft platform SDK Resource Compiler RC supports Unicode characters in resource files and file names, as well as new Vista resource types such as icons with alpha channel. The actual filename of the RC compiler... more (see page 213)

WSDLIMP.EXE, the Command Line WSDL Import Tool (see page 214)	WSDLIMP generates code to represent the types and APIs that a WSDL document defines. This code can be used to write client applications that call on the Web Service that the WSDL (Web Services Description Language) document describes. If you want to write a server that implements the Web Service, one of the command line options tells the importer to generate implementation classes that you can then complete by filling in the bodies of the generated methods. **Note:** WSDLIMP ignores any definitions in the WSDL document for which it can't generate code. That is, it can only import Web Services... more (see page 214)

3.1.1.1 BCC32, the C++ Command-Line Compiler

The CodeGear C++ compiler (BCC32.EXE) is a resource compiler shell. It invokes BRCC32 and RLINK32, depending on the command-line syntax.

Command Line Syntax

```
bcc32 [option [option...}] <filename> [<filename>...]
```

Use spaces to separate the command-line compiler name, each option, and the filenames. Precede each option by either a hyphen (-) or a forward slash (/). For example:

```
BCC32 -Ic:\code\hfiles
```

You can also specify options in configuration (.CFG) files, which are described in a following section.

You can use BCC32 to send .OBJ files to ILINK32 or .ASM files to TASM32 (if you have TASM32 installed on your machine).

See the BCC32 Command Line Help for Detailed Information

To display the BCC32.exe command line help in the cmd window, include the –h command line option.

For example, to display a list of the commonly used compiler command line options, type:

```
BCC32 -h
```

The displayed list indicates the options that are enabled by default (*):

```
C:\>bcc32 -h CodeGear C++ 5.92 for Win32 Copyright (c) 1993, 2007 CodeGear
Available options (* = default setting, xxx = has sub-options: use -h -X):
(Note: -X- or -w-XXX will usually undo whatever was set or unset by -X)
  -3      Generate 80386 protected-mode compatible instructions
  -4      Generate 80386/80486 protected-mode compatible instructions
  -5      Generate Pentium instructions
  -6      Generate Pentium Pro instructions
  -Axxx   Enable ANSI conformance
  -B      Compile to .ASM (-S), then assemble to .OBJ
  -C      Enable nested comments
  -CP     Enable code paging (for MBCS)
  -D      -D <name> defines 'name' as a null string, or use -D<name>=<value>
  -E      Specify which assembler to use
  -G      Optimize for size/speed; use -O1 and -O2 instead
  -Hxxx   Generate and use precompiled headers
  -I      Set the include file search path
  -Jxxx   Template generation options
  -K      Set default character type to unsigned
  -L      Library file search path
  -M      Create a linker map file
  -O      Optimize jumps
  -P      Perform C++ compile regardless of source extension
  -Q      Extended compiler error information
  -R      Include browser information in generated .OBJ files
  -RF     Find references to symbol
* -RT     Enable runtime type information
  -S      Compile to assembly
  -T      Specify assembler option, e.g. -Tx
```

```
  -U      Undefine any previous definitions of name
  -Vxxx   Compatibility options
  -Wxxx   Target is a Windows application
  -X      Disable compiler autodependency output
  -axxx   Set data alignment boundary.  Default is -a8; -a- means -a1
* -b      Make enums integer-sized (-b- makes them short as possible)
  -c      Compile to object file only, do not link
  -d      Merge duplicate strings
  -dc     Put strings into the read-only data segment
  -dw     Put strings into the (writeable) data segment
  -e      Specify target executable pathname
* -ff     Fast floating point
  -fp     Correct Pentium FDIV flaw
* -fq     Use quiet floating point compare instruction (FUCOMP)
  -g      Stop batch compilation after n warnings (Default = 255)
  -h      Request help ('-h -' shows all help). Can be specific: -h -V
  -i      Set maximum significant identifier length (Default = 250)
  -j      Stop batch compilation after n errors (Default = None)
* -k      Generate standard stack frames
  -l      Pass options to the linker; example: -ls -l-x
  -m      Generate makefile dependency information
  -md     Put dependency info in .d files, not in the object file
  -mm     Ignore system header files while generating dependency info
  -mo     Specify the output file for dependency info
  -n      Set output directory for object files
  -o      Set output filename (-o<filename> or –o <filename> supported)
  -pxxx   Use Pascal calling convention
  -q      Suppress compiler identification banner
  -r      Use register variables
  -rd     Use register variables only when register keyword is employed
  -s      Link using the system's non-incremental linker
  -txxx   An alternate name for the -Wxxx switches; there is no difference
* -u      Generate underscores on symbol names
  -vxxx   Turn on source debugging
  -w      Display all warnings
  -w!     Return non-zero from compiler on warnings
  -xxxx   Enable exception handling
  -y      Debug line numbers on
  -z      Options for redefining standard segment names
```

Displaying Help for Specific Options, Groups such as -Axxx and -Vxxx

You can get more specific information about each of the multi-letter options, such as `-Axxx` (language compatibility and standards compliance) and `-Vxxx` (backward compatibility).

To do this, use the `-h` command line option with the initial letter of the option group (such as `-A` to specify the `-Axxx` options). BCC32 will display only the help topics for the specified set of options (such as –Axxx, –Vxxx or –Wxxx).

For example, to display a description of the -Axxx (language compatibility and standards compliance) options, use the –h and –A command line options:

```
C:\>bcc32 -h -A
CodeGear C++ 6.10 for Win32 Copyright (c) 1993-2008 CodeGear
Available options (* = default setting, xxx = has sub-options: use -h -X):
(Note: -X- or -w-XXX will usually undo whatever was set or unset by -X)
  -A      Enable ANSI conformance
  -AF     Use SUN Forte keywords and extensions
  -AG     Use GNU keywords and extensions
  -AK     Use Kernighan and Ritchie keywords and extensions
  -AT     Use CodeGear C++ keywords and extensions (also -A-)
  -AU     Use UNIX System V keywords and extensions
  -An     Use C99 keywords and extensions
  -Ax     Use C++-0x keywords and extensions
```

In the following example, the BCC32 command line help displays details about all the `-Vxxx` (backward compatibility) options:

```
C:\>bcc32 -h -V
CodeGear C++ 6.10 for Win32 Copyright (c) 1993-2008 CodeGear
Available options (* = default setting, xxx = has sub-options: use -h -X):
(Note: -X- or -w-XXX will usually undo whatever was set or unset by -X)
  -V      Compatibility options
  -V0     External C++ virtual tables
  -V1     Public C++ virtual tables
* -VA     Generate all global functions in their own virtual/weak segment
  -VC     Do not mangle calling convention into symbols
  -VF     MFC compatibility
  -VF3    Support MFC 3.2
  -VF4    Support MFC 4.0
* -VI     Use Microsoft search algorithm to locate header files
  -VM     Microsoft Visual C++ compatibility
  -Va     Support old-style class arguments
  -Vb     Enable backward compatability with Bcc versions 5.8.2 and earlier
  -Vbc    Don't collapse reference to reference and allow qualified references
  -Vbe    Allow old-style explicit template specialization
  -Vbn    Allow calling of non-const or non-volatile member function for a const
 or volatile object
  -Vbo    Use old Borland overload resolution rules
  -Vbr    Allow non-const reference binding
  -Vbs    Treat string literals as non-const
  -Vbt    Use old Borland type rules for ternary operators
  -Vbx    Allow explicit template specialization as a member function
  -Vc     Support constructor displacements
  -Vd     Use old C++ for-statement scoping rules
  -Ve     Zero-length empty base classes
  -Vg     Disable lexical digraph scanner
  -Vi     Use old 8.3 search algorithm to locate header files
  -Vl     Use old Borland class layout
  -Vm     Member pointer options
  -Vmd    Use the smallest possible representation for member pointers
  -Vmm    Support multiple inheritance for member pointers
  -Vmp    Honor declared precision of member pointers
  -Vms    Support single inheritance for member pointers
  -Vmv    Place no restrictions on where member pointers can point
  -Vn     Enable new operator names: and, or, and_eq, bitand, etc.
  -Vo     Set (almost) all compatibility flags; used with old code
  -Vp     Push 'this' first, as does Pascal
  -Vr     Reverse order for Multi-character constant
  -Vs     Use old-style virdef generation
  -Vt     Put virtual table pointer at front of object layout
  -Vv     Use 'slow' virtual base pointers
  -Vw     Emit native code instead of Unicode for multi-byte character
  -Vx     Zero-length empty class member functions
```

Default Settings

BCC32.EXE has specific options that are on by default. To turn off a default option or to override options in a configuration file, follow the option with a minus (-) sign.

Files with the .CPP extension compile as C++ files. Files with a .C extension, with no extension, or with extensions other than .CPP, .OBJ, .LIB, or .ASM compile as C files.

The compiler tries to link with a module-definition file with the same name as the executable, and extension .DEF.

General Compiler Output Options

Option	Description	Details
-c	Compiles to .OBJ, no link	Compiles and assembles the named .C, .CPP, and .ASM files, but does not execute a link on the resulting .OBJ files.
-e <filename>	Specify executable filename	Link file using <filename> as the name of the executable file. If you do not specify an executable name with this option, the linker creates an executable file based on the name of the first source file or object file listed in the command.
-l <x>	Pass option to linker.	Use this command-line option to pass option(s) <x> to the linker from a compile command. Use the command-line option `-l-x` to disable a specific linker option.
-M	Create a MAP file	Use this compiler option to instruct the linker to create a map file.
-o <filename>	Compike .OBJ to <filename>	Compiles the specified source file to <filename>.OBJ
-P	C++ compile	Causes the compiler to compile all source files as C++ files, regardless of their extension. Use -P- to compile all .CPP files as C++ source files and all other files as C source files. The command-line option -Pext causes the compiler to compile all source files as C++ files and it changes the default extension to whatever you specify with ext. This option is provided because some programmers use different extensions as their default extension for C++ code. The option -P-ext compiles files based on their extension (.CPP compiles to C++, all other extensions compile to C) and sets the default extension (other than .CPP).
-tWM	Generate a multi-threaded target	Creates a multi-threaded .EXE or .DLL. This option is not needed if you include a module definition file (.DEF file) in your compile and link commands which specify the type of 32-bit application you intend to build.

Compiler option precedence rules

The command-line compilers evaluate options from left to right, and follow these rules:

- If you duplicate any option (except for the options -D, -I, -L, or -U), the last option typed overrides any earlier one.
- Options typed at the command line override configuration and response file options except for the -D, -I, -L, and -U options, which are cumulative.

Specifying directories in command line options

The CodeGear C++ compiler can search multiple directories for include and library files. The syntax for the library directories option (-L) and the include directories option (-I), (like the #define option (-D)) allows multiple listings of a given option. Here is the syntax for these options:

```
-L <dirname> [<dirname>;...]
-I <dirname> [<dirname>;...]
```

The parameter <dirname> used with -L and -I can be any directory or directory path. You can enter these multiple directories on the command line in the following ways

- You can stack multiple entries with a single -L or -I option by using a semicolon: `BCC32.EXE –L dirname1;dirname2;dirname3 –I include1;include2;include3 myfile.c`
- You can place more than one of each option on the command line, like this: `BCC32.EXE –L dirname1 –L dirname2 –L dirname3 –I include1 –I include2 –I include3 myfile.c`
- You can mix styles: `BCC32.EXE –L dirname1;dirname2 –Ldirname3 –I include1;include2 –I include3`

```
myfile.c
```

If you list multiple -L or -I options on the command line, the result is cumulative. The compiler searches all the directories listed, in order from left to right.

Using compiler configuration files (.CFG files)

If you repeatedly use a certain set of options, you can list them in a configuration file instead of continually typing them on the command line. A configuration file is a standard ASCII text file that contains one or more command-line options. Each option must be separated by a space or a new line.

Whenever you issue a compile command, BCC32.EXE searches for a configuration file called BCC32.CFG. The compiler looks for the .CFG file first in the directory where you issue the compile command, then in the directory where the compiler is located.

You can create and use multiple configuration files in addition to using the default .CFG file.

To use a configuration file, use the following syntax where you would place the compiler options:

```
+[path]filename
```

For example, you could use the following command line to use a configuration file called MYCONFIG.CFG:

```
BCC32 +C:\MYPROJ\MYCONFIG.CFG mycode.cpp
```

Options typed on the command line override settings stored in configuration files except for the prepended options -D, -I, -L, and -U.

Using response files

Response files let you list both compiler options and file names in a single file (unlike configuration files, which accept only compiler options). A response file is a standard ASCII text file that contains one or more command-line options and/or file names, with each entry in the file separated by a space or a new line. In addition to simplifying your compile commands, response files let you issue a longer command line than most operating systems allow.

The syntax for using a single response file is:

```
BCC32 @[path]respfile.txt
```

The syntax for using multiple response files is:

```
BCC32 @[path]respfile.txt @[path]otheresp.txt
```

Response files typically have an .RSP extension.

Options typed at the command line override any option or file name in a response file except for -D, -I, -L, and -U, which are prepended.

RLINK32.DLL (see page 204)

BRCC32.EXE (see page 165)

3.1.1.2 BRC32, the Resource Shell

The Borland resource compiler (BRC32) is a resource compiler shell. It invokes BRCC32 and RLINK32, depending on the command-line syntax.

Command Line Syntax

```
brc32 [options] <filename>.RC [<filename>.EXE]
```

To display command line help, enter:

```
brc32
```

Command Line Options

Option	Description
-d<name> [=string]	Defines a symbol you can test with the #IFDEF preprocessor directive.
-fo<filename>	Renames the .RES file.
-fe<filename>	Renames the .EXE file.
-i<path>	Adds one or more directories (separated by semicolons) to the include search path.
-k	Disables the contiguous preload of segments and resources in the .EXE file. Segments are kept in the order in which they appear in the .DEF file. (This option only applies to 16-bit resources and is disabled when the -r option is in effect.)
-r	Creates a .RES file only. The compiled .RES file is not added to the .EXE.
-v	Prints progress messages (verbose listing).
-x	Directs the compiler to ignore the INCLUDE environment variable when it searches for include or resource files.
-16	Builds 16–bit .RES files.
-32	Builds 32–bit .RES files.
-Vd.d	Makes the .EXE file with Windows version provided (v3.1 is the default for 16-bit resources; -v4.0 is the default for 32-bit resources). Version options are listed in the following table.

Version Options (Used with —Vd.d Option)

Option	Bit	Resulting Look
3.1	16	Gives white background with a non 3-D look for Windows 3.1x, Windows 32s, or WinNT 3.1
4.0	16	Gives gray 3-D look for Windows 95 and WinNT 3.51
3.1	32	Gives white background with a non 3-D look for Windows 32s or WinNT 3.1
4.0	32	Gives gray 3-D look for Windows 95 and WinNT 3.51

Options for Downward Compatibility

Option	Description
-t	Creates an application that runs only in protected mode (Windows Standard or 386 Enhanced mode).
-31	Builds Windows 3.1-compatible .RES files.
-w32	Builds Win32-compatible .RES files.

Resource Shell Examples

The following statement compiles the .RC file, creates a .RES file, and adds the .RES file to the executable file:

```
brc32 <filename>.RC <filename>.EXE
```

BRC32 automatically seeks an .EXE file with the same name as the .RC file. You need to specify the .EXE file only if its name is different from that of the .RC file.

The following statement creates a .RES file, but not an .EXE file. If you name an .EXE file in the command line, BRC ignores it:

```
brc32 -r <filename>.EXE
```

The following statement adds an existing .RES file to an executable file. The .EXE file name is required only if it differs from the .RES file name:

```
brc32 <filename>.RES <filename>.EXE
```

This example uses BRC32 to build a 16-bit Windows 3.1 compatible .RES file:

```
brc32 -16 -v3.1 -fo<filename>.RES <filename>.RC
```

RLINK32.DLL (see page 204)

BRCC32.EXE (see page 165)

3.1.1.3 BRCC32.EXE, the Resource Compiler

BRCC32 is the command-line version of the resource compiler. It accepts a resource script file (.RC) as input and produces a resource object file (.RES) as output.

RAD Studio provides a choice in resource compilers. You can choose to use either BRCC32 or RC (the Microsoft SDK resource compiler) on the **Project** ▸ **Options** ▸ **Resource Compiler** dialog box.

Command Line Syntax

```
BRCC32 [<options>] <filename>
```

To display command line help, enter:

```
brcc32
```

Or add the help flag:

```
brcc32 -h
```

BRCC32 Command Options

Option	Description
@<responsefile>	Takes instructions from the specified command file.
-c <codepage>	Uses the specified code page for resource translation. If -c is not used, the default ANSI code page is used.
-d<name>[=<string>]	Defines a preprocessor symbol.
-fo<filename>	Renames the output .RES file. (By default, BRCC32 creates the output .RES file with the same name as the input .RC file.)
-i<path>	Adds one or more directories (separated by semicolons) to the include search path.
-l<language>	Specifies default language.
-m	Indicates that the code page specified with the -c switch contains double-byte character set (DBCS) characters.
-r	This switch is ignored. It is included for compatibility with other resource compilers.
-v	Prints progress messages (verbose).
-x	Deletes the current include path.
-h or ?	Displays help.

-16	Builds a 16–bit resource.
-32	Builds a 32–bit resource.

BRCC32 predefines common resource-related Windows constants such as WS_VISIBLE and BS_PUSHBUTTON. Also, two special compiler-related symbols are defined: RC_INVOKED and WORKSHOP_INVOKED. These symbols can be used in the source text in conjunction with conditional preprocessor statements to control compilation.

For example, the following construct can greatly speed up compilation:

```
#ifndef WORKSHOP_INVOKED#include “windows.h” #endif
```

Downward Compatibility

The following syntax and options are supported for downward compatibility:

Option	Description
-16	Builds 16–bit .RES files.
-32	Builds 32–bit .RES files.
-31	Builds Windows 3.1–compatible .RES files.
-w32	Builds Win32–compatible .RES files.

BRC32.EXE (see page 163)

RC.EXE (see page 213)

3.1.1.4 COFF2OMF.EXE, the Import Library Conversion Tool

COFF2OMF converts a COFF import library file (InputFile) to a corresponding OMF import library file (OutputFile). COFF2OMF.EXE is located in the C++Builder \bin directory.

Command Line Syntax

```
Coff2Omf [<options>] InputFile OutputFile
```

To display command line help, enter:

```
coff2omf
```

COFF2OMF converts the publicly exported symbols in the COFF import library into a corresponding set of symbols in the OMF import library. COFF2OMF enables C++Builder users to link to Microsoft and other third-party DLLs that use the COFF format. COFF2OMF does not convert .OBJ files.

Run the COFF2OMF tool on a COFF import library created for a specific DLL, and use the resulting import library to link OMF format EXEs and DLLs to the COFF DLL.

Command Line Option	Description
-q	Quiet mode. Converts without writing tool and copyright information to standard output.
-v	Dumps selected symbols. Dumps the converted symbols to standard output, which can be redirected to an output file.
-h or -?	Displays help.

-r	Removes (deletes) output file if empty. Deletes the output file if there is an error and the conversion results in an empty file.
-lib:xx	Specifies options for OMF import library generation. The xx options can be: • ms — Allow entries that have MS C++ name mangling. The default is No. • st — Normalize names instead of aliasing MS stdcall mangling. • ca — Don't perform MS cdecl aliasing. Default is to alias.

3.1.1.5 CPP32.EXE, the C Compiler Preprocessor

CPP32.EXE produces a file that lists a C or C++ program, in which all #include files and #define macros have been expanded. While you do not need to use the preprocessor during normal compilation, you may find the list file helpful for debugging purposes.

Often, when the compiler reports an error inside a macro or an include file, you can get more information about what the error is if you can see the include files or the results of the macro expansions. In many multi-pass compilers, a separate pass performs this work, and the results of the pass can be examined. Because the CodeGear C++ compiler is a single-pass compiler, use CPP32 to get the first-pass functionality found

For each file processed by CPP32, the output is written to a file in the current directory (or the output directory named by the -n option) with the same name as the source name but with an extension of .I.

This output file is a text file containing each line of the source file and any include files. Any preprocessing directive lines have been removed, along with any conditional text lines excluded from the compile. Unless you use a command-line option to specify otherwise, text lines are prefixed with the file name and line number of the source or include file the line came from. Within a text line, any macros are replaced with their expansion text. Use the -Sr option to produce a file which doesn't have line numbers. You can then pass this file to the compiler (use the -P compiler option to force a C++ compile).

Command Line Syntax

```
CPP32 [<options>] <filename[s]>
```

To display command line help, enter:

```
cpp32 -h
```

CPP32 recognizes all the same options that BCC32 does, except for the following additions for the -S option (Control preprocessed output format):

Option	Description
-Sc	Keep comments in preprocessed file.
-Sd	Keep defines in preprocessed file.
-Sk	Keep output on errors.
-Sr	Make output readable by preserving comments and indentations
-Ss	Show statistics of file names and line counts.

CPP32 as a Macro Preprocessor

CPP32 can be used as a macro preprocessor; the resulting .i file can then be compiled with BCC32. The following simple program illustrates how CPP32 preprocesses a file.

Source file: HELLOFB.C

```
#define NAME “Frank CodeGear” #define BEGIN { #define END } main() BEGIN
        printf(“%s\n”, NAME);p END
```

CPP32 Command Line

```
CPP32 HELLOFB.C
```

Output (written to HELLOFB.I)

```
/* HELLOFP.C 1: */

/* HELLOFP.C 2: */

/* HELLOFP.C 3: */

/* HELLOFP.C 4: */

/* HELLOFP.C 5: */main()

/* HELLOFP.C 6: */printf("%s\n", "Frank CodeGear");

/* HELLOFP.C 7: */}

/* HELLOFP.C 8: */}
```

Using MIDL with CPP32

MIDL (Microsoft Interface Definition Language) is an RPC compiler. In order to use MIDL with the C++ preprocessor (CPP32.EXE), you must use the following MIDL command:

Option	Description
-<cpp_cmd> {<CPP32>}	Tells MIDL which preprocessor to use when processing an .IDL or .ACF file. MIDL calls the preprocessor to expand macros within source files.
-<cpp_opt> "{<options>}"	Specifies the command line options for the preprocessor. The -Sr option removes line number and file name information from each line of the preprocessed output. The -oCON option indicates that preprocessed output should go to standard output, instead of to file. The preprocessor banner and the current file that is being processed are not emitted. Including -oCON within a .CFG file processed by the preprocessor causes the banner to be emitted.
{<CPP32 options>}	Passes the options to CPP32.
{<MIDL options>}	Any MIDL command-line options.
{<.idl/.acf file>	The source file that MIDL processes.

BCC32, CPP32 and UUIDs

In some cases, CPP32 does not accept valid UUIDs. For example, a valid UUID statement is:

```
uuid(5630EAA0-CA48-1067-B320-00DD010662DB)
```

When CPP32 encounters 5630EAA0, it is classified as a floating-point number, and since it is an invalid floating point number, the preprocessor emits an error. To work around this problem, enclose the UUID within quotes. When using MIDL with CPP32, use the -ms_ext option. The UUID statement becomes:

```
uuid("5630EAA0-CA48-1067-B320-00DD010662DB")
```

and the MIDL command line becomes:

```
MIDL -ms_ext -cpp_cmd CPP32 -cpp_opt " -oCON {<CPP32 options>}" {<MIDL options>} {<.idl/.acf
```

```
file>}
```

3.1.1.6 DCC32.EXE, the Delphi Command Line Compiler

DCC32 is the Delphi (Object Pascal) command line compiler.

To display command line help, enter:

```
dcc32
```

or:

```
dcc32 –h
```

or:

```
dcc32 –help
C:\>dcc32
CodeGear Delphi for Win32 compiler version 18.5
Copyright (c) 1983,2007 CodeGear

Syntax: dcc32 [options] filename [options]

  -A <unit>=<alias> = Set unit alias
  -B = Build all units
  -CC = Console target
  -CG = GUI target
  -D<syms> = Define conditionals
  -E<path> = EXE/DLL output directory
  -F<offset> = Find error
  -GD = Detailed map file
  -GP = Map file with publics
  -GS = Map file with segments
  -H = Output hint messages
  -I<paths> = Include directories
  -J = Generate C .obj file
  -JP = Generate C++ object file
  -JPN = Generate C++ .obj, include namespace
  -JPE = Generate C++ .obj, export all symbols
  -JPH = Generate C++ .obj, export symbols, generate header .hpp files
  -JPHNE = Generate C++ .obj file, .hpp file, in namespace, export all
  -JL = Generate package .lib, .bpi, and all .hpp files for C++
  -K<addr> = Set image base addr
  -LE<path> = package .bpl output directory
  -LN<path> = package .dcp output directory
  -LU<package> = Use package
  -M = Make modified units
  -N0<package> = Use package
  -M = Make modified units
  -N0<path> = unit .dcu output directory
  -NH<path> = unit .hpp output directory
  -NO<path> = unit .obj output directory
  -NB<path> = unit .bpi output directory
  -NS<namespace> = Namespace search path
  -O<paths>  = Object directories
  -P = look for 8.3 file names also
  -Q = Quiet compile
  -R<paths> = Resource directories
  -U<paths> = Unit directories
  -V = Debug information in EXE
  -VR = Generate remote debug (RSM)
```

```
    -W[+|-][warn_id] = Output warning messages
    -Z = Output 'never build' DCPs
    -$<dir> = Compiler directive
    --help = Show this help screen
    --version = Show name and version
    --codepage:<cp> = specify source file encoding
    --default-namespace:<namespace> = set namespace
    --depends = output unit dependency information
    --doc = output XML documentation
    --drc = output resource string .drc file
    --no-config = do not load default DCC32.CFG file
    --description:<string> = set executable description
  Compiler switches: -$<state> (defaults are shown below)
    A8  Aligned record fields
    B-  Full boolean Evaluation
    C+  Evaluate assertions at runtime
    D+  Debug information
    G+  Use imported data references
    H+  Use long strings by default
    I+  I/O checking
    J-  Writeable structured consts
    L+  Local debug symbols
    M-  Runtime type info
    O+  Optimization
    P+  Open string params
    Q-  Integer overflow checking
    R-  Range checking
    T-  Typed @ operator
    U-  Pentium(tm)-safe divide
    V+  Strict var-strings
    W-  Generate stack frames
    X+  Extended syntax
    Y+  Symbol reference info
    Z1  Minimum size of enum types
```

Creating C++ Files from DCC32

If you want to generate .hpp files (and the corresponding .obj) from a .pas file, you should use -JPHNE.

You can also use -JL on the .dpk file containing the .pas file.

3.1.1.7 GREP.EXE, the text search utility

GREP (Global Regular Expression Print) is a powerful text-search program derived from the UNIX utility of the same name. GREP searches for a text pattern in one or more files or in its standard input stream.

Using GREP

Here is a quick example of a situation where you might want to use GREP. Suppose you wanted to find out which text files in your current directory contained the string "Bob". You would type:

```
grep Bob *.txt
```

GREP responds with a list of the lines in each file (if any) that contained the string "Bob". Because GREP does not ignore case by default, the strings "bob" and "boB" do not match.

GREP can do a lot more than match a single, fixed string. You can make GREP search for any string that matches a particular pattern. (See GREP: The search string.)

Command Line Syntax

The general command-line syntax for GREP is

```
grep [-<options>] <searchstring> [<files(s)>...]
```

To display a list of the GREP command line options, special characters, and defaults for GREP, enter:

```
grep ?
```

GREP Command Line Options

Option	Description
<options>	Consists of one or more letters, preceded by a hyphen (-), that changes the behavior of GREP.
<searchstring>	Gives the pattern to search for.
<file(s)>	Tells GREP which files to search. (If you do not specify a file, GREP searches standard input; this lets you use pipes and redirection.) Files can be an explicit file name or a generic file name incorporating the DOS ? and * wildcards. In addition, you can type a path (drive and directory information). If you list files without a path, GREP searches the current directory. If you do not specify any files, input to GREP must come from redirection (<) or a vertical bar (|).

Redirecting Output from GREP

If you find that the results of your GREP are longer than one screen, you can redirect the output to a file.

For example, you could use this command:

```
GREP "Bob" *.txt > temp.txt
```

This command searches all files with the TXT extension in the current directory, then puts the results in a file called TEMP.TXT. (You can name this file anything you like.) Use any word processor to read TEMP.TXT (the results of the search).

GREP Command Line Options

You can pass options to the GREP utility on the command line by specifying one or more single characters preceded by a hyphen (-). Each individual character is a switch that you can turn on or off: A plus symbol (+) after a character turns the option on; a hyphen (-) after the character turns the option off. The + sign is optional; for example, -r means the same thing as -r+. You can list multiple options individually (like this: -i -d -l), or you can combine them (like this: -ild or -il, -d, and so on).

Here are the GREP option characters and their meanings:

Command Line Options for GREP

Option	Description
-c	Count only: Prints only a count of matching lines. For each file that contains at least one matching line, GREP prints the file name and a count of the number of matching lines. Matching lines are not printed. This option is off by default.
-d	Search subdirectories: For each file specified on the command line, GREP searches for all files that match the file specification, both in the directory specified and in all subdirectories below the specified directory. If you give a file without a path, GREP assumes the files are in the current directory. This option is off by default.
-e	Search expression follows: Indicates that the next argument is the search expression. This option is useful when you want to search for an expression that begins with "-".
-i	Ignore case: GREP ignores upper/lowercase differences. When this option is on, GREP treats all letters a to z as identical to the corresponding letters A to Z in all situations. This option is off by default.
-l	List file names only: Prints only the name of each file containing a match. After GREP finds a match, it prints the file name and processing immediately moves on to the next file. This option is off by default.
-n	Line numbers: Each matching line that GREP prints is preceded by its line number. This option is off by default.

-o	UNIX output format: Changes the output format of matching lines to support more easily the UNIX style of command-line piping. All lines of output are preceded by the name of the file that contained the matching line. This option is off by default.
-r	Regular expression search: The text defined by searchstring is treated as a regular expression instead of as a literal string. This option is on by default. A regular expression is one or more occurrences of one or more characters optionally enclosed in quotes. The following symbols are treated specially: • ^ start of line • . any character • * match zero or more chatacteres • [aeiou0-9] match a, e, i, o, u, and 0-9 • [^aeiou0-9] match all but a, e, i, o, u, and 0-9 • $ end of line • \ quote next character • + match one or more
-u <filename>	Update options: Creates a copy of GREP.EXE called <filename>.EXE. Any options included on the command line are saved as defaults in the new copy of GREP. Use the -u option to customize the default option settings. To verify that the defaults have been set correctly, type filename ?; each option on the help screen is followed by a + or - to indicate its default setting.
-v	Nonmatch: Prints only nonmatching lines. Only lines that do not contain the search string are considered nonmatching lines. This option is off by default.
-w	Word search: Text found that matches the regular expression is considered a match only if the character immediately preceding and following cannot be part of a word. The default word character set includes A to Z, 0 to 9, and the underscore (_). This option is off by default. An alternate form of this option lets you specify the set of legal word characters. Its form is -w[set], where set is any valid regular expression. If you define the set with alphabetic characters, it is automatically defined to contain both the uppercase and lowercase values for each letter in the set (regardless of how it is typed), even if the search is case-sensitive. If you use the -w option in combination with the -u option, the new set of legal characters is saved as the default set.
-z	Verbose: GREP prints the file name of every file searched. Each matching line is preceded by its line number. A count of matching lines in each file is given, even if the count is zero. This option is off by default.
?	Displays a help screen showing the options, special characters, and defaults for GREP.

The Search String

The value of <searchstring> defines the pattern GREP searches for. A search string can be either a regular expression or a literal string.

- In a regular expression, certain characters have special meanings: They are operators that govern the search. (A regular expression is either a single character or a set of characters enclosed in brackets. A concatenation of regular expressions is a regular expression.)
- In a literal string, there are no operators: Each character is treated literally.

You can enclose the search string in quotation marks to prevent spaces and tabs from being treated as delimiters. To search for an expression that begins with "-", use the -e option. The text matched by the search string cannot cross line boundaries; that is, all the text necessary to match the pattern must be on a single line.

When you use the -r option (on by default), the search string is treated as a regular expression (not a literal expression).

The following characters have special meanings:

Symbol	Description
^	A circumflex at the start of the expression matches the start of a line.
$	A dollar sign at the end of the expression matches the end of a line.
.	A period matches any character.
*	An asterisk after a character matches any number of occurrences of that character followed by any characters, including zero characters. For example, bo* matches bot, boo, as well as bo.
+	A plus sign after a character matches any number of occurrences of that character followed by any characters, except zero characters. For example, bo+ matches bot and boo, but not b, bo, or bt.
{}	Characters or expressions in braces are grouped so that the evaluation of a search pattern can be controlled and so grouped text can be referred to by number.
[]	Characters in brackets match any one character that appears in the brackets, but no others. For example [bot] matches b, o, or t.
[^]	A circumflex at the start of the string in brackets means NOT. Hence, [^bot] matches any characters except b, o, or t.
[-]	A hyphen within the brackets signifies a range of characters. For example, [b-o] matches any character from b through o..
\	A backslash before a wildcard character tells GREP to treat that character literally, not as a wildcard. For example, \^ matches ^ and does not look for the start of a line.

Four of the "special" characters ($, ., *, and +) do not have any special meaning when used within a bracketed set. In addition, the character ^ is only treated specially if it immediately follows the beginning of the set definition (immediately after the [delimiter).

GREP Examples

Example 1

```
grep -r "[^a-z]main\ *\(" *.c
```

Matches:

```
main(i,j:integer)
if (main ()) halt;
if (MAIN ()) halt;
```

Does Not Match:

```
mymain()
```

Explanation: The search string tells GREP to search for the word main with no preceding lowercase letters ([^a-z]), followed by zero or more occurrences of blank spaces (\ *), then a left parenthesis. Since spaces and tabs are normally considered command-line delimiters, you must quote them if you want to include them as part of a regular expression.

Example 2

```
grep -ri [a-c]:\\data\.fil *.c *.inc
```

Matches:

```
A:\data.fil
B:\DATA.FIL
c:\Data.Fil
```

Does Not Match:

```
d:\data.fil a:data.fil
```

Explanation: Because the backslash (\) and period (.) characters usually have special meaning in path and file names, you must place the backslash escape character immediately in front of them if you want to search for them. The -i option is used here, so the search is not case sensitive.

Example 3

```
grep "search string with spaces" *.doc *.c
```

Matches:

```
A search string with spaces in it.
```

Does not match

```
This search string has spaces in it.
```

Explanation: This is an example of how to search for a string containing specific text.

Example 4

```
grep -rd "[ ,.:?'\"]"$ \*.doc
```

Matches:

```
He said hi to me.
Where are you going?
In anticipation of a unique situation,
Examples include the following:
"Many men smoke, but fu man chu."Explanation
```

Does not match:

```
He said "Hi" to me
Where are you going? I'm headed to the
```

Explanation: This example searches for any one of the characters " . : ? ' and , at the end of a line. The double quote within the range is preceded by an escape character so it is treated as a normal character instead of as the ending quote for the string. Also, the $ character appears outside of the quoted string. This demonstrates how regular expressions can be concatenated to form a longer expression.

Example 5

```
grep -w[=] = *.c
```

Matches:

```
i = 5;
j=5;
i += j;
```

Does not match:

```
if (i == t) j++;
/* ================================== */
```

This example redefines the current set of legal characters for a word as the assignment operator (=) only, then does a word search. It matches C assignment statements, which use a single equal sign (=), but not equality tests, which use a double equal sign (==).

BCC32.EXE (see page 159)

3.1.1.8 ILINK32.EXE, the Incremental Linker

ILINK32 links object modules (.OBJ files), library modules (.LIB files), and resources to produce executable files (.EXE, .DLL, and .BPL files). ILINK32 creates and maintains a series of state files that contains this information. These state files allow subsequent links to be incremental, greatly reducing the total link time.

Command Line Syntax

```
ILINK32 [@<respfile>][<options>] <startup> <myobjs>, [<exe>], [<mapfile>], [<libraries>], [<deffile>], [<resfile>]
```

To display command line help, enter:

```
ilink32
```

Linker command-line options are case-sensitive.

The linker can also use a configuration file called ILINK32.CFG for options that you'd typically type at the command-line.

Element	Description
[@<respfile>]	A response file is an ASCII file that lists linker options and file names that you would normally type at the command line. By placing options and file names in a response file, you can save the amount of keystrokes you need to type to link your application.
<options>	Linker options that control how the linker works. For example, options specify whether to produce an .EXE, .BPL, or .DLL file. Linker options must be preceded by either a slash (/) or a hyphen (-).
<startup>	A CodeGear initialization module for executables or DLLs that arranges the order of the various segments of the program. Failure to link in the correct initialization module usually results in a long list of error messages telling you that certain identifiers are unresolved, or that no stack has been created.
<myobjs>	The .OBJ files you want linked. Specify the path if the files aren't in the current directory. (The linker appends an .OBJ extensions if no extension is present.)
<exe>	The name you want given to the executable file (.EXE, .BPL, or .DLL). If you don't specify an executable file name, ILINK32 derives the name of the executable by appending .EXE, .BPL, or .DLL to the first object file name listed. (The linker assumes or appends an .EXE extensions for executable files if no extension is present. It also appends a .DLL extension for dynamic link libraries if no extension is present. Similarly, the linker appends a .BPL extension for package files if no extension is present.)
<mapfile>	The name you want given to the map file. If you don't specify a name, the map file name is the same as the .EXE file (but with the .MAP extension). (The linker appends a .MAP extension if you do not specify an extension.)
<libraries>	The library files you want included at link time. Do not use commas to separate the libraries listed. If a file is not in the current directory or the search path (see the /L option) then you must include the path in the link statement. (The linker appends a .LIB extension if no extension is present.) The order in which you list the libraries is very important; be sure to use the order defined in this list: 1. Code Guard libraries (if needed) 2. Any of your own user libraries (note that if a function is defined more than once, the linker uses the first definition encountered) 3. IMPORT32.LIB (if you are creating an executable that uses the Windows API) 4. Math libraries 5. Runtime libraries
<deffile>	The module definition file for a Windows executable. If you don't specify a module definition (.DEF) file and you have used the `/Twd` or `/Twe` option, the linker creates an application based on default settings. (The linker appends a .DEF extension if no extension is present.)
<resfile>	A list of .RES files (compiled resource files) to bind to the executable. (The linker appends an .RES extension if no extension is present.)

Linker Options

Option	Description
@xxxx	Uses the response file `xxxx`.
/A:dd	Specifies file alignment (backward compatibility switch, use /Af).
/Af:nnnn	Specifies file alignment; set nnnn in hex or decimal. nnnn must be a power of 2. Default is 0x200 = 512 byte boundaries.
/Ao:nnnn	Specifies object alignment; set nnnn in hex or decimal. nnnn must be a power of 2. Default is 0x1000 = 4096 byte boundaries.
/aa	Builds a 32-bit Windows application.
/ad	Builds a 32-bit Windows device driver.
/ap	Builds a 32-bit Windows console application.
/B:xxxx	Specifies the image base address and removes the relocation table.
/b:xxxx	Specifies the image base address, and preserves DLL relocation table. Successive objects are aligned on 64K linear address boundaries. Improves load-time and runtime performance.Recommended for producing DLLs. Default is Off.
/C	Refreshes the linker state files. Erases all linker state files before each link; then recreates the files and continues with the link.
/c	Treats case as significant in public and external symbols. Default is On.
/d	Delay-loads a DLL. The specified DLL is not loaded or initialized until an entrypoint in the DLL is actually called.
/D:xxxx	Saves the specified description in the PE image.
/Enn	Specifies the max. number of errors.
/GC	Inserts a comment string ino the image directly after the object table in the PE file header. You can specify more than one string. Default is Off.
/GD	Generates a Delphi compatible RC file (DRC file). Default is Off.
/GF:xxxx	Sets image flags. The xxxx flags are: • `-GF SWAPNET` copies the image to a local swap file and runts it from there if the image resides on a network drive. • `-GF SWAPCD` copies the image to a local swap file and runs it if the image resides on removable media (CD, zip drive). • `-GF UNIPROCESSOR` prevents the application from running on a multiprocessor system. • `-GF LARGEADDRESSAWARE` tells the OS that the application understands addresses larger than 4G. • `-GF AGGRESSIVE` aggressively trims the workingg seet of an application when the application is idel (suited for screen savers and other processes that you want to stay out of the way of main line processes).
/Gk	Keeps output files on error. Default is Off.
/Gl	Generates a .LIB file.
/Gpd	Generates design-time-only package. Default is: the package works at both design time and runtime.
/Gpr	Generate runtime-only package Default is: the package works at both design time and runtime.
/Gn	Don't generate state files (disable incremental linking). Subsequent links will take just as long as the first one. Default is Off.

/Gs:string=[EICRWSDKP]	Set section flags. Adds the specified flag(s) to the existing flags for a given section, but cannot remove default flags from a section.
	Section flags are:
	`E = Executable`
	`C = Contains code`
	`I = Contains initialized data`
	`R = Section is readable`
	`W = Section is writable`
	`S = Section is shared`
	`D = Section is discardable`
	`K = Section must not be cached`
	`P = Section must not be paged`
	Example -GS:.rsrc=W This switch makes the RSRC section writable.

/Gz	Calculate checksum of target and insert result in PE header. Used for NT Kernel mode drivers and system DLLs. Default is Off.
/H:xxxx	Specifies application heap reserve size in hex or decimal. Minimum value is 0. This switch overrides the HEAPSIZE sestting in a module definition file. Default is 1 MB (0x1000000).
/HC:nnnn	Specifies application heap commit size.
/I	Specifies the directory for intermediate output files. Directs linker state files, but the MAP file and TDS files are saved in the same directory as the output image, unless otherwise specified for the MAP file.
/j	Specifies object search paths. **Example** ILINK32 /jc:\myobjs;.\objs splash .\common\logo,,,utils logolib This command directs the linker to first search the current directory for SPLASH.OBJ. If the file is not found in the current directory, the linker then searches the C:\MYOBJS directory, and then the .\OBJs directory. However, the linker does not use the object search paths to find the file LOGO.OBJ because an explicit path was given for this file.
/L	Specifies the library search path to use if no explicit path is given for the LIB file and the linker cannot find the LIB file in the current directory. **Example** ILINK32 /Lc:\mylibs;.\libs splash .\common\logo,,,utils logolib directs the linker to first search the current directory for SPLASH.LIB. If the file is not found in the current directory, the linker then searches the C:\MYLIBS directory, and then the .\LIBs directory. However, the linker does not use the library search paths to find the file LOGO.LIB because an explicit path was given for this file.
/M	Prints the mangled C++ identifiers in the map file, not the full name.
/m	The segments listing has a line for each segment, showing the segment starting address, segment length, segment name, and the segment class. The public symbols are broken down into two lists, the first showing the symbols in sorted alphabetically, the second showing the symbols in increasing address order. Symbols with absolute addresses are tagged Abs. A list of public symbols is useful when debugging.:Many debuggers use public symbols, which lets you refer to symbolic addresses while debugging.
/q	Suppresses command line banner.
/r	Verbose linking. Default is Off.
/Rr	Replaces resources.
/S:xxxx	Specifies application stack reserve size.
/Sc:xxxx	Specifies application stack commit size.
/s	Produces a detailed map file of segments.
/Tpd	Targets a 32-bit Windows DLL file.

/Tpe	Targets a 32-bit Windows EXE file.
/Tpp	Generates a package.
/t	Displays time spent on link.
/w	Turns all warnings on.
/w-dee	Disables the warning: ".EXE module built with a .DLL or BPL extension."
/w-dpl	Disables the warning: "Duplicate symbol in library.".
/w-dup	Disables the warning: "Duplicate symbol."
/w-exp	Enables the warning: "Attempt to export non-public symbol.."
/w-nou	Disables the warning: "Creating a package without any units."
/w-rty	Enables the warning: "Unable to perform incremental link - performing full link".
/w-srd	Disables the warning: "Stripping relocations from a DLL may cause it to malfunction."
/w-snf	Disables the warning: "Section not found."
/w-uld	Disables the warning: "Unable to load DLL."
/x	Suppresses creation of a MAP file.
(blank)	Default map file of segments (no linker switch, map file created by default)

Linker Response Files

You can use response files with the command-line linker to specify linker options.

Response files are ASCII files that list linker options and file names that you would normally type at the command line. Response files allow you longer command lines than most operating systems support, plus you don't have to continually type the same information. Response files can include the same information as configuration files, but they also support the inclusion of file names.

Unlike the command line, a response file can be several lines long. To specify an added line, end a line with a plus character (+) and continue the command on the next line. Note that if a line ends with an option that uses the plus to turn it on (such as /v+), the + is not treated as a line continuation character (to continue the line, use /v+ +).

If you separate command-line components (such as .OBJ files from .LIB files) by lines in a response file, you must leave out the comma used to separate them on the command line.

For example:

```
/c c0ws+
myprog,myexe +
mymap +
mylib cws
```

leaves out the commas you'd have to type if you put the information on the command line:

```
ILINK32 /c c0ws myprog,myexe,mymap,mylib cws
```

To use response files:

1. Type the command-line options and file names into an ASCII text file and save the file. Response files typically have an .RSP extension.
2. Type: ILINK32 @[<path>]<RESFILE.RSP> where <RESFILE.RSP> is the name of your response file.

You can specify more than one responses file, as follows:

```
ilink32 /c @listobjs.rsp,myexe,mymap,@listlibs.rsp
```

Note: You can add comments to response files using semicolons; the linker ignores any text on a line that follows a semicolon.

Module Definition Files

The module definition file is an ASCII text file that provides information to ILINK32 about the contents and system requirements of a Windows application. You can create a module definition file using IMPDEF.EXE, and you can create import libraries from module definition files using IMPLIB.EXE.

If no module definition file is specified, the following defaults are assumed:

```
CODE        PRELOAD MOVEABLE DISCARDABLE
DATA            PRELOAD MOVEABLE MULTIPLE    (for applications)
            PRELOAD MOVEABLE SINGLE    (for DLLs)
HEAPSIZE    4096
STACKSIZE   1048576
```

To change an application's attributes from these defaults, you need to create a module definition file.

If you delete the EXETYPE statement, the linker can determine what kind of executable you want to produce from the options you supply on the command line.

You can include an import library to substitute for the IMPORTS section of the module definition.

You can use the __declspec(dllexport) or _export keywords in the definitions of export functions in your C and C++ source code to remove the need for an EXPORTS section. Note, however, that if __declspec(dllexport) or _export is used to export a function, that function is exported by name rather than by ordinal. Please also note that __declspec(dllexport) is the preferred method of export

Linker-State Files

The four linker-state files have file names of <Project>.IL?, where <Project> is taken from the name of the project .BPR file, and the character in place of the question mark (?) identifies each of the four individual linker-state files.

Debug Information File

If you include debug information in your final linked executable, ILINK32 will always store the debug information in a separate .TDS file, named <Project Name>.TDS by default. The debugger should be able to read this debugger-information file. ILINK32 will always create this file. If you do not have the -v linker switch set, the TDS file is marked as invalid.

RLINK32.EXE (see page 204)

IMPDEF.EXE (see page 179)

Module Definition Files (see page 199)

3.1.1.9 IMPDEF.EXE, the Module Definition Manager

Import libraries provide access to the functions in a Windows DLL. Import libraries contain records. Each record contains the name of a DLL and specifies where in the DLL the imported functions reside. These records are bound to the application by the linker and provide Windows with the information necessary to resolve DLL function calls. You can substitute an import library for part or all of the IMPORTS section of a module definition file.

IMPDEF takes as input a DLL name, and produces as output a module definition file with an EXPORTS section containing the names of functions exported by the DLL.

Command Line Syntax

```
IMPDEF <options> <destination.def> <source.dll>
```

Option	Description
-a	Adds '_' alias for cdecl functions for compatibility with Microsoft libraries
-h	Emits hints

For example:

```
IMPDEF DestName.DEF SourceName.DLL
```

To display command line help, enter:

```
impdef
```

This creates a module definition file named DestName.DEF from the file SourceName.DLL. The resulting module definition file would look something like this:

```
LIBRARY     <FileName>
DESCRIPTION '<Description>'
EXPORTS
            <ExportFuncName>              @<Ordinal>
        .
        .
        .
            <ExportFuncName>              @<Ordinal>
```

- **<FileName>** is the root file name of the DLL.
- **'<Description>'** is the value of the DESCRIPTION statement if the DLL was previously linked with a module definition file that included a DESCRIPTION statement.
- **<ExportFuncName>** names an exported function.
- **<Ordinal>** is that function's ordinal value (an integer).

Classes in a DLL

IMPDEF is useful for a DLL that uses C++ classes. If you use the __declspec (or _export) keyword when defining a class, all of the non-inline member functions and static data members for that class are exported. It's easier to let IMPDEF make a module definition file for you because it lists all the exported functions, and automatically includes the member functions and static data members.

Since the names of these functions are mangled, it would be tedious to list them all in the EXPORTS section of a module definition file simply to create an import library from the module definition file. If you use IMPDEF to create the module definition file, it will include the ordinal value for each exported function. If the exported name is mangled, IMPDEF will also include that function's unmangled, original name as a comment following the function entry. So, for instance:

```
LIBRARY     <FileName>
DESCRIPTION '<Description>'
EXPORTS
            <MangledExportFuncName>  @<Ordinal> ; <ExportFuncName>
        .
        .
        .
            <MangledExportFuncName>  @<Ordinal> ; <ExportFuncName>
```

- **<FileName>** is the root file name of the DLL.
- **'<Description>'** is the value of the DESCRIPTION statement if the DLL was previously linked with a module definition file that included a DESCRIPTION statement.
- **<MangledExportFuncName>** provides the mangled name.
- **<Ordinal>** is that function's ordinal value (an integer).
- **<ExportFuncName>** gives the function's original name.

Functions in a DLL

IMPDEF creates an editable source file that lists all the exported functions in the DLL. You can edit this .DEF file to contain only those functions that you want to make available to a particular application, then run IMPLIB on the edited .DEF file. This results in an import library that contains import information for a specific subset of a DLL's export functions.

Suppose you're distributing a DLL that provides functions to be used by several applications. Every export function in the DLL is defined with __declspec (or _export). Now, if all the applications used all the DLL's exports, then you could use IMPLIB to make one import library for the DLL. You could deliver that import library with the DLL, and it would provide import information for all of the DLL's exports. The import library could be linked to any application, thus eliminating the need for the particular application to list every DLL function it uses in the IMPORTS section of its module definition file.

But suppose you want to give only a few of the DLL's exports to a particular application. Ideally, you want a customized import library to be linked to that application--an import library that provides import information only for the subset of functions that the application will use. All of the other export functions in the DLL will be hidden to that client application.

To create an import library that satisfies these conditions, run IMPDEF on the compiled and linked DLL. IMPDEF produces a module definition file that contains an EXPORT section listing all of the DLL's export functions. You can edit that module definition file, remove the EXPORTS section entries for those functions you don't want in the customized import library, and then run IMPLIB on the module definition file. The result will be an import library that contains import information for only those export functions listed in the EXPORTS section of the module definition file.

Module Definition Files (see page 199)

3.1.1.10 IMPLIB.EXE, the Import Library Tool

IMPLIB takes as input either DLLs or module definition files, or both, and produces an import library as output.

If you've created a Windows application, you've already used IMPORT32.LIB, the import library for the standard Windows DLLs. IMPORT32.LIB is linked automatically when you build a Win32 application in the C++Builder IDE and when using BCC32 at the command line.

An import library lists some or all of the exported functions for one or more DLLs. IMPLIB creates an import library directly from DLLs or from module definition files for DLLs (or a combination of the two).

Command Line Syntax

```
IMPLIB <options> <LibName> [< DefFiles>... | <DLLs>... ] [@<ResponseFile> | <sourcename> ]
[<sourcename> ...]
```

To display command line help, enter:

```
implib
```

Command Line Element	Description
<options>	An optional list of one or more of the following IMPLIB command options: • **-a** Adds '_' alias for cdecl functions for compatibility with Microsoft libraries. If the identifier already begins with an underscore (_), it is skipped (unless you use the -aa option). • **-aa** Forces the creation of an '_' alias for cdecl functions for compatibility with Microsoft libraries. If the identifier begins with an underscore (_), the -aa option adds a second underscore. • **-c** Emits warning on case sensitive symbols. • **-f** Forces imports by name. • **-w** Emits no warnings.
<LibName>	The name for the new import library.
<DefFiles>	One or more existing module definition files for one or more DLLs. You must specify at least one DLL or module definition file.
<DLLs>	One or more existing DLLs. You must specify at least one DLL or one module definition file.
@<ResponseFile>	An ACSII text file that contains a list of DEF and DLL files that you want to process using IMPLIB. In the response file, separate the filenames using either spaces or new lines.
<sourcename>	Either a DEF or DLL file that is to be processed by IMPLIB.

Example

```
implib foo.lib @respon.txt
```

Note: A DLL can also have an extension of .EXE or .DRV, not just .DLL.

IMPDEF.EXE (see page 179)

3.1.1.11 Using Include Files

In C++, include files always have the file extension .h.

Include File Search Algorithms

The CodeGear C++ compiler searches for files included in your source code with the #include directive in the following ways:

- If you specify a path and/or directory with your include statement, the compiler searches only the specified location. For example, if you have the following statement in your code: `#include "c:\C++\include\vcl\vcl.h"` the header file vcl.h must reside in the directory C:\C++\include. In addition, if you use the statement: `#include <vcl\vcl.h>` and you set the Include option (-I) to specify the path C:\C++\include, the file vcl.h must reside in C:\C++\include\vcl, and not in C:\C++include or C:\vcl.
- If you put a #include <somefile> statement in your source code, the compiler searches for "somefile" only in the directories specified with the Include (-I) option.
- If you put a #include "somefile" statement in your code, the compiler will search for "somefile" in the following order:

1. The same directory as the file containing the #include statement.
2. The directories of flies that include (#include) that file.
3. The current directory
4. The directories specified with the include (-I) option

Library File Search Algorithms

The library file search algorithms are similar to those for include files:

- **Implicit libraries:** The CodeGear C++ compiler searches for implicit libraries only in the specified library directories; this is similar to the search algorithm for: `#include "somefile"` Implicit library files are the ones the compiler automatically links in and the start-up object file (C0x.OBJ).
- **Explicit libraries:** Where the compiler searches for explicit (user-specified) libraries depends in part on how you list the library file name. Explicit library files are ones you list on the command line or in a project file; these are file names with a .LIB extension.
- If you list an explicit library file name with no drive or directory (such as MYLIB.LIB), the compiler first searches for that library in the current directory. If the first search is unsuccessful, the compiler looks in the directories specified with the Library (-L) option. This is similar to the search algorithm for #include "somefile".
- If you list a user-specified library with drive and/or directory information (like this: c:\mystuff\mylib1.lib), the CodeGear C++ compiler searches only in the location you explicitly listed as part of the library path name and not in any specified library directories.

3.1.1.12 MAKE

MAKE.EXE is a command-line utility that helps you manage project compilation and link cycles. MAKE is not inherently tied to compiling and linking, but is a more generic tool for executing commands based on file dependencies. MAKE helps you quickly build projects by compiling only the files you have modified since the last compilation. In addition, you can set up rules that specify how MAKE should deal with the special circumstances in your builds.

MAKE Basics

MAKE uses rules you write along with its default settings to determine how it should compile the files in your project. For example, you can specify when to build your projects with debug information and to compile your .OBJ files only if the date/time stamps of a source file is more recent than the .OBJ itself. If you need to force the compilation of a module, use TOUCH.EXE to modify the time stamp of one of the module's dependents.

In an ASCII makefile, you write explicit and implicit rules to tell MAKE how to treat the files in your project; MAKE determines if it should execute a command on a file or set of files using the rules you set up. Although your commands usually tell MAKE to compile or link a set of files, you can specify nearly any operating system command with MAKE.

Command Line Syntax

```
MAKE [<options>...][<target>[<target>]]
```

You must separate the MAKE command and the options and target arguments with spaces.

When specifying targets, you can use wildcard characters (such as * and ?) to indicate multiple files.

To display command line help, enter:

```
make –?
```

or:

```
make –h
```

Command Line Element	Description
[<options>]	MAKE options that control how MAKE works. See "Make Command Options" in this topic.

<target>	The name of the target listed in the makefile that you want to build

Default MAKE Actions

When you issue a MAKE command, MAKE looks for the file BUILTINS.MAK, a file that you create to contain the default rules for MAKE (use the -r option to ignore the default rules). MAKE looks for this file first in the current directory, then in the directory where MAKE.EXE is stored. After loading BUILTINS.MAK, MAKE looks in the current directory for a file called MAKEFILE or MAKEFILE.MAK (use the -f option to specify a file other than MAKEFILE). If MAKE can't find the makefile, it generates an error message.

After loading the makefile, MAKE tries to build only the first explicit target listed in the makefile by checking the time and date of the dependent files of the first target. If the dependent files are more recent than the target file, MAKE executes the commands to update the target.

If one of the first target's dependent files is used as a target elsewhere in the makefile, MAKE checks that target's dependencies and builds it before building the first target. This chain reaction is called a linked dependency.

If something during the build process fails, MAKE deletes the target file it was building. Use the `precious` directive if you want MAKE to keep the target when a build fails.

You can stop MAKE after issuing the MAKE command by pressing Ctrl+Break or Ctrl+C

About makefiles

A makefile is an ASCII file that contains the set of instructions that MAKE uses to build a certain project. Although MAKE assumes your makefile is called MAKEFILE or MAKEFILE.MAK, you can specify a different makefile name with the -f option.

MAKE either builds the target(s) you specify with the make command or it builds the first target it finds in the makefile. To build more than a single target, use a symbolic target in your makefile.

Makefiles can contain:

- Comments (precede a comment with a number sign [#])
- Explicit and implicit rules
- Macros
- Directives

Symbolic Targets

A symbolic target forces MAKE to build multiple targets in a makefile. When you specify a symbolic target, the dependency line lists all the targets you want to build (a symbolic target basically uses linked dependencies to build more than one target).

For example, the following makefile uses the symbolic target AllFiles to build both FILE1.EXE and FILE2.EXE:

```
AllFiles: file1.exe file2.exe #Note that AllFiles has no commands file1.exe: file1.obj
bcc32 file1.obj file2.exe: file2.obj        bcc32 file2.obj
```

Rules for symbolic targets

- Do not type a line of commands after the symbolic target line.
- A symbolic target must have a unique name; it cannot be the name of a file in your current directory.
- Symbolic target names must follow the operating system rules for naming files.

BUILTINS.MAK

You can create the optional file BUILTINS.MAK and store in it the standard rules and macros that you want MAKE to use when it builds the targets in a makefile. To ignore this file when it exists, use the -r MAKE option.

Here is a sample of a BUILTINS.MAK file:

```
#
# CodeGear C++ BUILTINS.MAK
#

CC = bcc32
RC = brcc32
AS = tasm32

.asm.obj:
    $(AS) $(AFLAGS) $&.asm

.c.exe:
    $(CC) $(CFLAGS) $&.c

.c.obj:
    $(CC) $(CFLAGS) /c $&.c

.cpp.exe:
    $(CC) $(CFLAGS) $&.cpp

.cpp.obj:
    $(CC) $(CPPFLAGS) /c $&.cpp

.rc.res:
    $(RC) $(RFLAGS) /r $&

.SUFFIXES: .exe .obj .asm .c .res .rc

!if !$d(BCEXAMPLEDIR)
BCEXAMPLEDIR = $(MAKEDIR)\..\EXAMPLES

!endif
```

MAKE Command Options

You can use command-line options to control the behavior of MAKE. MAKE options are case-sensitive and must be preceded with either a hyphen (-) or slash (/).

You must separate the MAKE command and the options and target arguments with spaces. When specifying targets, you can use wildcard characters (such as * and ?) to indicate multiple files. To get command-line help for MAKE, type MAKE -?.

For example, to use a file called PROJECTA.MAK as the makefile, type:

```
MAKE -fPROJECTA.MAK
```

Many of the command-line options have equivalent directives that you can use within the makefile.

Option	Description
-a	Checks dependencies of include files and nested include files associated with .OBJ files and updates the .OBJ if the .h file changed. See also -c.
-B	Builds all targets regardless of file dates.

-c	Caches autodependency information, which can improve MAKE speed. Use with -a. Do not use this option if MAKE modifies include files (which can happen if you use TOUCH in the makefile or if you create header or include files during the MAKE process).
-D<macro>	Defines macro as a single character, causing an expression !ifdef macro written in the makefile to return true.
-D<macro>=<string>	Defines <macro> as <string>. If <string> contains any spaces or tabs, enclose <string> in quotation marks. The -D is optional.
-d<directory>	Specifies the drive and the directory that MAKER (the real mode version of MAKE) uses when it swaps out of memory. This option must be used with -S. MAKE ignores this option.
-e	Ignores a macro if its name is the same as an environment variable. MAKE uses the environment variable instead of the macro.
-f<filename>	Uses <filename> or <fillename>.MAK instead of MAKEFILE (a space after -f is optional).
-h or: -?	Help. Displays the MAKE options. Default settings are shown with a trailing plus sign.
-I<directory>	Searches for include files in the current directory first, then in the specified directory.
-i	Ignores the exit status of all programs run from the makefile and continues the build process.
-K	Keeps temporary files that MAKE creates (MAKE typically deletes temporary files).
-m	Displays the date and timestamp of each file as MAKE processes it.
-n	Prints the MAKE commands but does not perform them. This is helpful for debugging makefiles.
-N	Causes MAKE to mimic Microsoft's NMAKE.
-p	Displays all macro definitions and implicit rules before executing the makefile.
-q	Returns 0 if the target is up-to-date and nonzero if it is not up-to-date (for use with batch files).
-r	Ignores any rules defined in BUILTINS.MAK.
-s	Suppresses onscreen command display (silent).
-S	Swaps MAKER out of memory while commands are executed, reducing memory overhead and allowing compilation of large modules. MAKE ignores this option.
-U<macro>	Undefines the previous macro definition of <macro>.
-W<filename>	Writes MAKE to <filename>, updating all non-string options.

MAKE Macros (see page 191)

MAKE Directives (see page 186)

MAKE Rules and Commands (see page 193)

3.1.1.13 MAKE Directives

MAKE directives resemble directives in languages such as C and Pascal. In MAKE, directives perform various control functions, such as displaying commands onscreen before executing them. MAKE directives begin either with an exclamation point or a period, and they override any options given on the command line. Directives that begin with an exclamation point must appear at the start of a new line.

The following table lists the MAKE directives and their corresponding command-line options:

Directive	Option (if available)	Description/Example
.autodepend	-a	Turns on autodependency checking. Autodependencies are the files that are automatically included in the targets you build, such as the header files included in your C++ source code. With .autodepend on, MAKE compares the dates and times of all the files used to build the .OBJ, including the autodependency files. If the dates or times of the files used to build the .OBJ are newer than the date/time stamp of the .OBJ file, the .OBJ file is recompiled. You can use .autodepend (or -a) in place of forming linked dependencies.
.cacheautodepend	-c	Turns on autodependency caching.
!cmdswitches		Uses + or - followed by non-string option letters to turn each option on or off. Spaces or tabs must appear before the + or - operator, none can appear between the operator and the option letters.
!elif		Acts like a C else if.
!else		Acts like a C else.
!endif		Ends an !if, !ifdef, or !ifndef statement

!error		Stops MAKE and prints an error message The syntax of the !error directive is: `!error <message>`
		MAKE stops processing and prints the following string when it encounters this directive:
		`Fatal makefile exit code: Error directive: <message>`
		Embed !error in conditional statements to abort processing and print an error message, as shown in the following example: `!if !$d(MYMACRO) #if MYMACRO isn't defined !error MYMACRO isn't defined ! endif`
		If MYMACRO isn't defined, MAKE terminates and prints:
		`Fatal makefile 4: Error directive: MYMACRO isn't defined`
		Error-Checking Controls: MAKE offers four different error-checking controls:
		• The .ignore directive turns off error checking for a selected portion of the makefile.
		• The -i command-line option turns off error checking for the entire makefile.
		• The -num prefix, which is entered as part of a rule, turns off error checking for the related command if the exit code exceeds the specified number.
		• The - prefix turns off error checking for the related command regardless of the exit code.

!if		Begins a conditional statement.
!ifdef		Acts like a C #ifdef, testing whether a given macro has been defined.
!ifndef		Acts like a C #ifndef, testing whether a given macro is undefined.
.ignore	-i	MAKE ignores the return value of a command.
!include		Acts like a C #include, specifying a file to include in the makefile. This directive is like the #include preprocessor directive for the C or C++ language -- it lets you include the text of another file in the makefile: !include <filename> You can enclose the filename in quotation marks (" ") or angle brackets (< >) and nest directives to unlimited depth, but writing duplicate !include directives in a makefile isn't permitted -- you'll get the error message cycle in the include file. Rules, commands, or directives must be complete within a single source file; you can't start a command in an !include file, then finish it in the makefile. MAKE searches for !include files in the current directory unless you've specified another directory with the -I command-line option.

.keep	-K	Keeps temporary files that MAKE creates (MAKE usually deletes them).

!message		Prints a message to stdout while MAKE runs the makefile
		The !message directive lets you send messages to the screen from a makefile. You can use these messages to help debug a makefile that isn't working properly. For example, if you're having trouble with a macro definition, you could put this line in your makefile:
		`!message The macro is defined here as: $(MacroName)`
		When MAKE interprets this line, it will print onscreen (assuming the macro expands to .CPP):
		`The macro is defined here as: .CPP`

.noautodepend	**a**	Turns off autodependency checking.
.nocacheautodepend	**c**	Turns off autodependency caching.
.noIgnore	**i**	Turns off .Ignore.
.nokeep	**K**	Does not keep temporary files that MAKE creates.
.nosilent	**s**	Displays commands before MAKE executes them.
.noswap	**S**	Tells MAKE not to swap iteself out of memory before executing a command.
.path.ext		Tells MAKE to search for files with the extension .ext in path directories To tell MAKE to look for files with the .c extension in C:\SOURCE or C:\CFILES and to look for files with the .obj extension in C:\OBJS: `.path.c = C:\CSOURCE;C:\CFILES .path.obj = C:\OBJS`
.precious		Saves the target or targets even if the build fails If a MAKE build fails, MAKE deletes the target file. The .precious directive prevents the file deletion, which you might desire for certain kinds of targets. For example, if your build fails to add a module to a library, you might not want the library to be deleted. The syntax for .precious is: `.precious: <target> [<target>...]`
.silent	-s	MAKE executes commands without printing them first.

.suffixes		Determines the implicit rule for ambiguous dependencies. The .suffixes directive tells MAKE the order (by file extensions) for building implicit rules. The syntax of .suffixes is:
		`.suffixes: .<ext> [.<ext> ...]`
		where .<ext> represents the dependent file extensions you list in your implicit rules.
		For example, you could include the line `.suffixes: .asm .c .cpp` to tell MAKE to interpret implicit rules beginning with the ones dependent on .ASM files, then .C files, then .CPP files, regardless of what order they appear in the makefile.
		The following .suffixes example tells MAKE to look for a source file first with an .ASM extension, next with a .C extension, and finally with a .CPP extension. If MAKE finds MYPROG.ASM, it builds MYPROG.OBJ from the assembler file by calling TASM. MAKE then calls ILINK32; otherwise, MAKE searches for MYPROG.C to build the .OBJ file or it searches for MYPROG.CPP.
		`.suffixes: .asm .c .cpp`
		`myprog.exe: myprog.obj`
		`bcc32 myprog.obj`
		`.cpp.obj:`
		`bcc32 -P -c $<`
		`.asm.obj:`
		`tasm /mx $`
		`.c.obj:`
		`bcc32 -P- -c $<`

.swap	-S	Tells MAKE to swap itself out of memory before executing a command.
!undef		Clears the definition of a macro. After this, the macro is undefined. !undef (undefine) causes an !ifdef MacroName test to fail. The syntax of the !undef directive is: `!undef MacroName`

Using Macros in Directives

You can use the $d macro with the !if conditional directive to perform some processing if a specific macro is defined. Follow the $d with macro name enclosed in parentheses or braces, as shown in the following example:

```
!if $d(DEBUG)           #If DEBUG is defined,
bcc32 -v f1.cpp f2.cpp   #compile with debug information;
!else                   #otherwise
bcc32 -v- f1.cpp f2.cpp   #don't include debug information.
!endif
```

Null Macros

you can substitute the characters .obj for the characters .cpp by using the following MAKE command:

```
NULLMACRO =
```

Either of the following lines can define a null macro on the MAKE command line:.

```
NULLMACRO =""
-DNULLMACRO
```

!if and Other Conditional Directives

The !if directive works like C if statements. As shown here, the syntax of !if and the other conditional directives resembles compiler conditionals:

!if condition	!if condition	!if condition	!ifdef macro
!endif	!else	!elif condition	!endif
	!endif	!endif	

The following expressions are equivalent:

```
!ifdef macro and !if $d(macro)
ifndef macro and !if !$d(macro)
```

These rules apply to conditional directives:

- One !else directive is allowed between !if, !ifdef, or !ifndef and !endif directives.
- Multiple !elif directives are allowed between !if, !ifdef, or !ifndef, !else and !endif.
- You can't split rules across conditional directives.
- You can nest conditional directives.
- !if, !ifdef, and !ifndef must have matching !endif directives within the same file.

The following information can be included between !if and !endif directives:

- Macro definition
- Explicit rule
- Implicit rule
- Include directive
- !error directive
- !undef directive

In an if statement, a conditional expression consists of decimal, octal, or hexadecimal constants and the operators shown in the following table:

Operator	Description	Operator	Description
-	Negation	?:	Conditional expression
~	Bit complement	!	Logical NOT
+	Addition	>>	Right shfit
-	Subtraction	<<	Left shift
*	Multiplication	&	Bitwise AND
/	Division	|	Bitwise OR
%	Remainder	^	Bitwise XOR
&&	Logical AND	>+	Greater than or equal to *
||	Logical OR	<+	Less than or equal to *
>	Greater than	==	Equality *
<	Less than	!=	Inequality *

- The Operator also works with string expressions.

MAKE evaluates a conditional expression as either a 32-bit signed integer or a character string.

MAKE Macros (see page 191)

MAKE Rules and Commands (see page 193)

3.1.1.14 MAKE Macros

A macro is a variable that MAKE expands into a string whenever MAKE encounters the macro in a makefile. For example, you can define a macro called LIBNAME that represents the string "mylib.lib." To do this, type the line LIBNAME = mylib.lib at the beginning of your makefile. Then, when MAKE encounters the macro $(LIBNAME), it substitutes the string mylib.lib. Macros let you create template makefiles that you can change to suit different projects.

To use a macro in a makefile, type $(MacroName) where MacroName is a defined macro. You can use either braces or parentheses to enclose MacroName.

MAKE expands macros at various times depending on where they appear in the makefile:

- Nested macros are expanded when the outer macro is invoked.
- Macros in rules and directives are expanded when MAKE first looks at the makefile.
- Macros in commands are expanded when the command is executed.

If MAKE finds an undefined macro in a makefile, it looks for an operating system environment variable of that name (usually defined with SET) and uses its definition as the expansion text. For example, if you wrote $(PATH) in a makefile and never defined PATH, MAKE would use the text you defined for PATH in your AUTOEXEC.BAT. See your operating system manuals for information on defining environment variables.

Syntax

```
<MacroName> = <expansion_text>
```

Element	Description
<MacroName>	Is case-sensitive (MACRO1 is different from Macro1). Limited to 512 characters.
<expansion_text>	Is limited to 4096 characters. Expansion characters may be alphanumeric, punctuation, or spaces.

You must define each macro on a separate line in your makefile and each macro definition must start on the first character of the line. For readability, macro definitions are usually put at the top of the makefile. If MAKE finds more than one definition of MacroName, the new definition overwrites the old one.

You can also define macros using the -D command-line option. No spaces are allowed before or after the equal sign (=); however, you can define more than one macro by separating the definitions with spaces. The following examples show macros defined at the command line:

```
make -Dsourcedir=c:\projecta
make -Dcommand="bcc32 -c"
make -Dcommand=bcc32 option=-c
```

Note: Macros defined in makefiles overwrite macros defined on the command line.

String Substitution in MAKE Macros

MAKE lets you temporarily substitute characters in a previously defined macro. For example, if you define the following macro:

```
SOURCE = f1.cpp f2.cpp f3.cpp
```

you can substitute the characters .obj for the characters .cpp by using the following MAKE command:

```
$(SOURCE:.cpp=.obj)
```

This substitution does not redefine the macro.

Rules for macro substitution:

- Syntax: `$(MacroName:original_text=new_text)`

- No space before or after the colon
- Characters in `original_text` must exactly match the characters in the macro definition (text is case-sensitive)

MAKE also lets you use macros within substitution macros. For example:

```
MYEXT=.C
SOURCE=f1.cpp f2.cpp f3.cpp
$(SOURCE:.cpp=$(MYEXT)) #Changes 'f1.cpp' to 'f1.C', etc.
```

The caret (^) symbol causes MAKE to interpret the next character literally. This is useful for inserting a new-line character. For example:

```
MYEXT=.C
SOURCE=f1.cpp f2.cpp f3.cpp
($(SOURCE):.cpp=$(MYEXT)^
)         # changes 'f1.cpp f2.cpp f3.cpp' to:
        # f1.C
        # f2.C
        # f3.C
```

Here, the caret tells MAKE to change each occurrence of .cpp to .C followed by the new-line character.

You can use this to create explicit rules that generate response files for TLIB.EXE. For example:

```
myfile.lib: file1.obj file2.obj file3.obj
TLIB $@ @&&!
+-$(**: = &^
+-)
!
```

Here, MAKE substitutes all space characters in the dependency list with a space followed by an ampersand (&) followed by the new-line character followed by "+-". The resulting response file looks like this:

```
+-file1.obj &
 +-file2.obj &
 +-file3.obj &
 +-
```

Default MAKE Macros

MAKE contains several default macros you can use in your makefiles. The following table lists the macro definition and what it expands to in explicit and implicit rules.

Macro	Expands in Implicit Rule	Expands in Explicit Rule
$*	path\dependent file	path\target file
$<	path\dependent file+ext	path\target file+ext
$:	path for dependents	path for target
$.	dependent file+ext	target file + ext
$&	dependent file	target file
$**	path\dependent file+ext	all dependents file+ext
$?	path\dependent file+ext	old dependents

Macro	Expands to	Comment
_ _MSDOS_ _	1	If running under DOS

_ _MAKE_ _	0x0370	MAKE's hex version number
MAKE	make	MAKE's executable file name
MAKEFLAGS	options	The options typed on the command line
MAKEDIR	directory	Directory where MAKE.EXE is located

Modifying Default MAKE Macros

If the default macros don't give you the exact string you want, macro modifiers let you extract parts of the string to suit your purpose. Macro modifiers are usually used with $< or $@.

To modify a default macro, use this syntax:

```
$(MacroName [modifier])
```

The following table lists macro modifiers and provides examples of their use:

Modifier	Part of File Name Expanded	Example	Result
D	Drive and directory	$(<D)	C:\PROJECTA\
F	Base and extension	$(<F)	MYSOURCE.C
B	Base only	$(<B)	MYSOURCE
R	Drive, directory, and base	$(<R)	C:\PROJA\SOURCE

MAKE Rules and Commands (see page 193)

3.1.1.15 MAKE Rules (Explicit and Implicit) and Commands

You write explicit and implicit rules to instruct MAKE how to build the targets in your makefile. In general, these rules are defined as follows:

- Explicit rules are instructions for specific files.
- Implicit rules are general instructions for files without explicit rules.

All the rules you write follow this general format:

```
Dependency line
  Command line
```

While the dependency line has a different syntax for explicit and implicit rules, the command line syntax stays the same for both rule types.

MAKE supports multiple dependency lines for a single target, and a single target can have multiple command lines. However, only one dependency line should contain a related command line. For example:

```
Target1: dependent1 dep2 dep3 dep4 dep5
Target1: dep6 dep7 dep8
    bcc32 -c $**
```

Explicit Rule Syntax

Explicit rules specify the instructions that MAKE must follow when it builds specific targets. Explicit rules name one or more targets followed by one or two colons. One colon means one rule is written for the target(s); two colons mean that two or more

rules are written for the target(s).

Explicit rules follow this syntax:

```
<target> [<target>...]:[:][{<path>}] [<dependent[s]>...]
    [<commands>]
```

Element	Description
<target>	Specifies the name and extension of the file to be built (a target must begin a line in the makefile -- you cannot precede the target name with spaces or tabs). To specify more than one target, separate the target names with spaces or tabs. Also, you cannot use a target name more than once in the target position of an explicit rule.
<path>	Is a list of directories that tells MAKE where to find the dependent files. Separate multiple directories with semicolons and enclosed the entire path specification in braces.
<dependent>	Is the file (or files) whose date and time MAKE checks to see if it is newer than target. Each dependent file must be preceded by a space. If a dependent appears elsewhere in the makefile as a target, MAKE updates or creates that target before using the dependent in the original target (this in known as a linked dependency).
<commands>	Are any operating system command or commands. You must indent the command line by at least one space or tab, otherwise they are interpreted as a target. Separate multiple commands with spaces.

If a dependency or command line continues on the following line, use a backslash (\) at the end of the first line to indicate that the line continues. For example:

```
MYSOURCE.EXE: FILE1.OBJ\     #Dependency line
FILE3.OBJ               #Dependency line continued
bcc32 file1.obj file3.obj  #Command line
```

Single Targets with Multiple Rules

A single target can have more than one explicit rule. To specify more than a single explicit rule, use a double colon (::) after the target name.

The following example shows targets with multiple rules and commands:

```
.cpp.obj:
   bcc32 -c -ncobj $<

.asm.obj:
   tasm /mx $<, asmobj\

mylib.lib :: f1.obj f2.obj #double colon specifies multiple rules
   echo Adding C files
   tlib mylib -+cobjf1 -+cobjf2

mylib.lib :: f3.obj f4.obj
   echo Adding ASM files
   tlib mylib -+asmobjf3 -+asmobjf4
```

Implicit Rule Syntax

An implicit rule specifies a general rule for how MAKE should build files that end with specific file extensions. Implicit rules start with either a path or a period. Their main components are file extensions separated by periods. The first extension belongs to the dependent, the second to the target.

If implicit dependents are out-of-date with respect to the target, or if the dependents don't exist, MAKE executes the commands associated with the rule. MAKE updates explicit dependents before it updates implicit dependents.

Implicit rules follow this basic syntax:

```
[{>source_dir>}].<source_ext>[{target_dir}].<target_ext>:
    [<commands>]
```

Element	Description
<source_dir>	Specifies the directory (or directories) containing the dependent files. Separate multiple directories with a semicolon.
.<source_ext>	Specifies the dependent filename extension.
<target_dir>	Specifies the directory where MAKE places the target files. The implicit rule will only be used for targets in this directory. Without specifying a target directory, targets from any directory will match the implicit rule.
.<target_ext>	Specifies the target filename extension. Macros are allowed here.
: (colon)	Marks the end of the dependency line.
<commands>	Are any operating system command or commands. You must indent the command line by at least one space or tab; otherwise they are interpreted as a target.

If two implicit rules match a target extension but no dependent exists, MAKE uses the implicit rule whose dependent's extension appears first in the .SUFFIXES list.

Explicit Rules with Implicit Commands

A target in an explicit rule can get its command line from an implicit rule. The following example shows an implicit rule followed by an explicit rule without a command line:

```
.c.obj:
    bcc32 -c $<    #This command uses a macro $< described later
myprog.obj:       #This explicit rule uses the command: bcc32 -c   myprog.c
```

The implicit rule command tells MAKE to compile MYPROG.C (the macro $< replaces the name myprog.obj with myprog.c).

MAKE Command Syntax

Commands immediately follow an explicit or implicit rule and must begin on a new line with a space or tab. Commands can be any operating system command, but they can also include MAKE macros, directives, and special operators that your operating system won't recognize (however, note that | can't be used in commands).

Here are some sample commands:

```
cd..
bcc32 -c mysource.c
COPY *.OBJ C:\PROJECTA
bcc32 -c $(SOURCE) #Macros in "Using MAKE macros"
```

Commands follow this general syntax:

```
[<prefix>...] <commands>
```

Command Prefixes

Commands in both implicit and explicit rules can have prefixes that modify how MAKE treats the commands. The following table lists the prefixes you can use in makefiles:

Prefix	Description
@	Does not display the command while it's being executed.
-<num>	Stops processing commands in the makefile when the exit code returned from command exceeds the integer num. Normally, MAKE aborts if the exit code is nonzero. No space is allowed between - and <num>.
-	Continues processing commands in the makefile, regardless of the exit codes they return.

&	Expands either the macro $**, which represents all dependent files, or the macro $?, which represents all dependent files stamped later than the target. Execute the command once for each dependent file in the expanded macro.
!	Behaves like the & prefix.

Using @

The following command uses the @ prefix, which prevents MAKE from displaying the command onscreen:

```
diff.exe : diff.obj
   @bcc32 diff.obj
```

Using -<num> and —

The prefixes -<num> and - (hyphen) control the makefile processing when errors occur. You can choose to continue with the MAKE process if any error occurs, or you can specify a number of errors to tolerate.

In the following example, MAKE continues processing if BCC32 returns errors:

```
target.exe : target.obj
target.obj : target.cpp
      -bcc32 -c target.cpp
```

Using &

The & prefix issues a command once for each dependent file. It is especially useful for commands that don't take a list of files as parameters. For example:

```
copyall : file1.cpp file2.cpp
    &copy $** c:\temp
```

invokes COPY twice, as follows:

```
copy file1.cpp c:\temp
copy file2.cpp c:\temp
```

Without the & modifier, MAKE would call COPY only once. **Note:** the & prefix only works with $** and $! macros.

MAKE Command Operators

While you can use any operating system command in a MAKE command section, you can also use the following special operators:

Operator	Description
<	Use input from a specified file rather than from standard input.
>	Send the output from command to file.
>>	Append the output from command to file.
<<	Create a temporary inline file and use its contents as standard input to command. Also, create temporary response file when -N is used. Note: this is only for use with Microsoft's NMAKE.
&&	Create a temporary response file and insert its name in the makefile.
<delimiter>	Use delimiters with temporary response files. You can use any character other than # as a delimiter. Use << and && as a starting and ending delimiter for a temporary file. Any characters on the same line and immediately following the starting delimiter are ignored. The closing delimiter must be written on a line by itself.

MAKE Directives (see page 186)

3.1.1.16 Message Options

Use the -w option to specify message options for the CodeGear C++ compiler:

- To enable a particular warning message, enter the -w option with a one- to three-letter option code.
- To disable the warning message, enter the -w- option with a one- to three- letter option code.

Examples

To display all warning and error messages, include the **-w** command option in your BCC32 command:

```
-w
```

To enable reporting of the warning "Mixing pointers to different 'char' types" (option code **ucp**, Default OFF), include the following flag in your BCC32 command:

```
-wucp
```

To disable reporting of the warning "Declaration ignored" (option code **dig**, Default ON), include the following flag in your BCC32 command:

```
-w-dig
```

To display help on the warning message codes, enter a compiler command that contains only the -h and -w options:

```
bcc32 -h -w
CodeGear C++ 5.92 for Win32 Copyright (c) 1993, 2007 CodeGear
Available options (* = default setting, xxx = has sub-options: use -h -X):
(Note: -X- or -w-XXX will usually undo whatever was set or unset by -X)
  -w      Display all warnings
  -w!     Return non-zero from compiler on warnings
  -wamb   8000 Ambiguous operators need parentheses
  -wamp   8001 Superfluous & with function
* -wasc   8002 Restarting compile using assembly
  -wasm   8003 Unknown assembler instruction
* -waus   8004 '%s' is assigned a value that is never used
* -wali   8086 Incorrect use of #pragma alias "aliasName"="substituteName"
* -watr   8100 '%s' attribute directive ignored
  -wbbf   8005 Bit fields must be signed or unsigned int
* -wbei   8006 Initializing %s with %s
* -wbig   8007 Hexadecimal value contains too many digits
* -wccc   8008 Condition is always %s
  -wcln   8009 Constant is long
* -wcom   8010 Continuation character \ found in // comment
* -wcpt   8011 Nonportable pointer comparison
* -wcsu   8012 Comparing signed and unsigned values
* -wcod   8093 Incorrect use of #pragma codeseg [seg_name] ["seg_class"] [grou

  -wdef   8013 Possible use of '%s' before definition
* -wdig   8014 Declaration ignored
* -wdpu   8015 Declare '%s' prior to use in prototype
* -wdsz   8016 Array size for 'delete' ignored
* -wdup   8017 Redefinition of '%s' is not identical
* -weas   8018 Assigning %s to %s
* -weff   8019 Code has no effect
* -wext   8020 '%s' is declared as both external and static
  -wexc   8101 Extern C linkage ignored
* -whch   8021 Handler for '%s' hidden by previous handler for '%s'
* -whid   8022 '%s' hides virtual function '%s'
* -wias   8023 Array variable '%s' is near
* -wibc   8024 Base class '%s' is also a base class of '%s'
* -will   8025 Ill-formed pragma
  -winl   8026 Functions %s are not expanded inline
  -winl   8027 Functions containing %s are not expanded inline
```

```
* -wifr   8085 Function '%s' redefined as non-inline
  -wimp   8102 Implicit conversion of '%s' to '%s'
* -wlin   8028 Temporary used to initialize '%s'
* -wlvc   8029 Temporary used for parameter '%s'
* -wlvc   8030 Temporary used for parameter '%s' in call to '%s'
* -wlvc   8031 Temporary used for parameter %d
* -wlvc   8032 Temporary used for parameter %d in call to '%s'
* -wmpc   8033 Conversion to '%s' will fail for members of virtual base '%s'
* -wmpd   8034 Maximum precision used for member pointer type '%s'
* -wmsg   8035 %s
* -wmes   8095 Incorrect use of #pragma message( "string" )
* -wmcs   8096 Incorrect use of #pragma code_seg(["seg_name"[,"seg_class"]])
* -wmcc   8098 Multi-character character constant
  -wnak   8036 Non-ANSI keyword used: '%s'
  -wnak   8036 Non-ANSI keyword used: '%s'
* -wncf   8037 Non-const function %s called for const object
* -wnci   8038 Constant member '%s' is not initialized
* -wncl   8039 Constructor initializer list ignored
* -wnfd   8040 Function body ignored
* -wngu   8041 Negating unsigned value
* -wnin   8042 Initializer for object '%s' ignored
* -wnma   8043 Macro definition ignored
* -wnmu   8044 #undef directive ignored
  -wnod   8045 No declaration for function '%s'
* -wnop   8046 Pragma option pop with no matching option push
* -wnsf   8047 Declaration of static function '%s(...)' ignored
* -wnst   8048 Use qualified name to access member type '%s'
* -wntd   8049 Use '< <' for nested templates instead of '<<'
* -wnto   8050 No type OBJ file present.  Disabling external types option.
* -wnvf   8051 Non-volatile function %s called for volatile object
* -wnpp   8083 Pragma pack pop with no matching pack push
* -wobi   8052 Base initialization without a class name is now obsolete
* -wobs   8053 '%s' is obsolete
* -wofp   8054 Style of function definition is now obsolete
* -wosh   8055 Possible overflow in shift operation
* -wovf   8056 Integer arithmetic overflow
* -wonr   8097 Not all options can be restored at this time
* -wpar   8057 Parameter '%s' is never used
* -wpch   8058 Cannot create pre-compiled header: %s
* -wpck   8059 Structure packing size has changed
* -wpia   8060 Possibly incorrect assignment
  -wpin   8061 Initialization is only partially bracketed
* -wpow   8062 Previous options and warnings not restored
* -wpre   8063 Overloaded prefix 'operator %s' used as a postfix operator
* -wpro   8064 Call to function with no prototype
* -wpro   8065 Call to function '%s' with no prototype
  -wprc   8084 Suggest parentheses to clarify precedence
* -wpcm   8094 Incorrect use of #pragma comment( <type> [,"string"] )
* -wpsb   8099 Static `main' is not treated as an entry point
* -wrch   8066 Unreachable code
* -wret   8067 Both return and return with a value used
* -wrng   8068 Constant out of range in comparison
* -wrpt   8069 Nonportable pointer conversion
* -wrvl   8070 Function should return a value
  -wsig   8071 Conversion may lose significant digits
* -wspa   8072 Suspicious pointer arithmetic
  -wstu   8073 Undefined structure '%s'
  -wstv   8074 Structure passed by value
* -wsus   8075 Suspicious pointer conversion
  -wstl   8087 '%s::operator==' must be publicly visible to be contained by a '% s'
  -wstl   8089 '%s::operator<' must be publicly visible to be contained by a '%s'
  -wstl   8090 '%s::operator<' must be publicly visible to be used with '%s'
  -wstl   8091 %s argument %s passed to '%s' is a %s iterator: %s iterator required
  -wstl   8092 %s argument %s passed to '%s' is not an iterator: %s iterator required
* -wtai   8076 Template instance '%s' is already instantiated
* -wtes   8077 Explicitly specializing an explicitly specialized class member makes no sense
```

```
* -wthr   8078 Throw expression violates exception specification
  -wucp   8079 Mixing pointers to different 'char' types
  -wuse   8080 '%s' is declared but never used
* -wvoi   8081 void functions may not return a value
* -wzdi   8082 Division by zero
```

3.1.1.17 Module Definition Files

You use module definition files with ILINK32. A module definition file is an ASCII text file that provides information to ILINK32 about the contents and system requirements of a Windows application. Use IMPDEF to create a module definition file.

The module definition file names the .EXE or .DLL, identifies the application type, lists imported and exported functions, describes the code section and data segment attributes, lets you specify attributes for additional code sections and data segments, specifies the size of the stack, and provides for the inclusion of a stub program.

CODE Statement

Defines the default attributes of code sections. Code sections can have any name, but must belong to section classes whose name ends in CODE (such as CODE or MYCODE).

```
CODE [PRELOAD | LOADONCALL]
      [EXECUTEONLY | EXECUTEREAD]
```

- **PRELOAD** means code is loaded when the calling program is loaded.
- **LOADONCALL** (the default) means the code is loaded when called by the program.
- **EXECUTEONLY** means a code section can only be executed.
- **EXECUTEREAD** (the default) means the code section can be read and executed.
- **FIXED** (the default) means the section remains at a fixed memory location.
- **MOVEABLE** means the sction can be moved.
- **DISCARDABLE** means the section can be discarded if it is no longer needed (this implies MOVEABLE).
- **NONDISCARDABLE** (the default) means the section can not be discarded.

DATA Statement

Defines attributes of data segments:

```
DATA [NONE | SINGLE | MULTIPLE]
     [READONLY | READWRITE]
     [PRELOAD | LOADONCALL]
     [SHARED | NONSHARED]
```

- **NONE** means that there is no data section created. This option is available only for libraries.
- **SINGLE** (the default for .DLLs) means a single data section is created and shared by all processes.
- **MULTIPLE** (the default for .EXEs) means that a data section is created for each process.
- **READONLY** means the data section can be read only.
- **READWRITE** (the default) means the data section can be read and written to.
- **PRELOAD** means the data section is loaded when a module that uses it is first loaded.
- **LOADONCALL** (the default) means the data section is loaded when it is first accessed. (LOADONCALL is ignored for 32-bit applications.)
- **SHARED** means one copy of the data section is shared among all processes.
- **NONSHARED** (the default for programs .DLLs) means a copy of the data section is loaded for each process needing to use the data section.

DESCRIPTION Statement (optional)

Inserts text into the application module and is typically used to embed author, date, or copyright information:

```
DESCRIPTION 'Text'
```

Text is an ASCII string delimited with single quotes.

EXETYPE Statement

Defines the default executable file (.EXE) header type for applications. You can leave this section in for 32-bit applications for backward compatibility, but if you need to change the EXETYPE, see the NAME statement.

```
EXETYPE  [WINDOWAPI] | [WINDOWCOMPAT]
```

- **WINDOWAPI** is a Windows executable, and is equivalent to the ILINK32 option -aa.
- **WINDOWCOMPAT** is a Windows-compatible character-mode executable, and is equivalent to the ILINK32 option -ap.

EXPORTS Statement

Defines the names and attributes of functions to be exported. The EXPORTS keyword marks the beginning of the definitions. It can be followed by any number of export definitions, each on a separate line.

```
EXPORTS
   <EsportName> [<Ordinal>]
   [RESIDENTNAME] [<Parameter>]
```

- **<ExportName>** specifies an ASCII string that defines the symbol to be exported as follows: `<EntryName> [=<InternalName>]` **<EntryName>** is the name listed in the executable file's entry table and is externally visible. **<InternalName>** is the name used within the application to refer to this entry.
- **<Ordinal>** defines the function's ordinal value as follows: `@<ordinal>` where `<ordinal>` is an integer value that specifies the function's ordinal value. When an application or DLL module calls a function exported from a DLL, the calling module can refer to the function by name or by ordinal value. It is faster to refer to the function by ordinal because string comparisons aren't required to locate the function. To use less memory, export a function by ordinal (from the point of view of that function's DLL) and import/call a function by ordinal (from the point of view of the calling module). When a function is exported by ordinal, the name resides in the nonresident name table. When a function is exported by name, the name resides in the resident name table. The resident name table for a module is in memory whenever the module is loaded; the nonresident name table isn't.
- **RESIDENTNAME** specifies that the function's name must be resident at all times. This is useful only when exporting by ordinal (when the name wouldn't be resident by default).
- **<Parameter>** is an optional integer value that specifies the number of words the function expects to be passed as parameters.

HEAPSIZE Statement

Defines the number of bytes the application needs for its local heap. An application uses the local heap whenever it allocates local memory.

```
HEAPSIZE <Reserve>[, <Commit>]
```

- **<Reserve>** can be a decimal or hex value, the default of which is 1MB. To help with backward (16-bit) compatibility for 32-bit ports, the linker uses the default value of 1MB if you specify in the .DEF ile a reserve value less than 64K.
- **<Commit>** is a decimal or hex value. The commit size is optional, and if not specified defaults to 4K. The minimum commit size you can specify is 0. In addition, the specified or default commit size must always be smaller or equal to the reserve size.

Reserved memory refers to the maximum amount of memory that can be allocated either in physical memory or in the paging file. In other words, reserved memory specifies the maximum possible heap size. The operating system guarantees that the specified amount of memory will be reserved and, if necessary, allocated.

The meaning of committed memory varies among operating systems. In Windows NT, commited memory refers to the amount of physical memory allocated for the heap at application load/initialization time. Committed memory causes space to be allocated either in physical memory or in the paging file. A higher commit value saves time when the application needs more heap space, but increases memory requirements and possible startup time.

You can override any heap reserve or commit size specified in the .DEF file with the -H or -Hc ILINK32 command-line options. -H lets you specify a heap reserve size less than the 64K minimum allowed in the .DEF file.

IMPORTS Statement

Defines the names and attributes of functions to be imported from DLLs. The IMPORTS keyword marks the beginning of the definitions followed by any number of import definitions, each on a separate line.

```
IMPORTS [<InternalName>=]<ModuleName>.<Entry>
```

- **<InternalName>** is an ASCII string that specifies the unique name the application uses to call the function.
- **<ModuleName>** specifies one or more uppercase ASCII characters that define the name of the executable module containing the function. The module name must match the name of the executable file. For example, the file SAMPLE.DLL has the module name SAMPLE.
- **<Entry>** specifies the function to be imported--either an ASCII string that names the function or an integer that gives the function's ordinal value.

Instead of listing imported DLL functions in the IMPORTS statement, you can either specify an import library for the DLL in the ILINK32 command line, or include the import library for the DLL in the project manager in the IDE.

You must use either __declspec(dllimport) or __import to import any function, class, or data you want imported. The prefered method is to use __declspec(dllimport)

The IMPORTS keyword can also be applied to (global) variables, as follows:

```
[ in the dll source file (dll.cpp) ] int sample = 100;

[ dll.def ]     EXPORTS       _sample

[ in application source file (app.cpp) ]
int _declspec(dllimport) sample;

[ app.def ]
  IMPORTS
    dll._sample
```

LIBRARY Statement

Defines the name of a DLL module. A module definition file can contain either a LIBRARY statement to indicate a .DLL or a NAME statement to indicate a .EXE. A library's module name must match the name of the executable file. For example, the library MYLIB.DLL has the module name MYLIB.

```
LIBRARY <LibrarName> [INITGLOBAL | INITINSTANCE]
```

- **<LibraryName>** (optional) is an ASCII string that defines the name of the library module. If you don't include a LibraryName, ILINK32 uses the file name with the extension removed. If the module definition file includes neither a NAME nor a LIBRARY statement, ILINK32 assumes a NAME statement without a ModuleName parameter.
- **INITGLOBAL** means the library-initialization routine is called.
- **INITINSTANCE** means the library-initialization routine is called each time a new process uses the library.

NAME Statement

Is the name of the application's executable module. The module name identifies the module when exporting functions. NAME must appear before EXETYPE. If NAME and EXETYPE don't specify the same target type, the linker uses the type listed with NAME.

```
NAME <ModuleName> [WINDOWSAPI] | [WINDOWCOMPAT]
```

- **<ModuleName>** (optional) specifiesone or more uppercase ASCII characters that name the executable module. The name must match the name of the executable file. For example, an application with the executable file SAMPLE.EXE has the module name SAMPLE. If <ModuleName> is missing, ILINK32 assumes that the module name matches the file name of the executable file. For example, if you do not specify a module name and the executable file is named MYAPP.EXE, ILINK32 assumes that the module name is MYAPP. If the module definition file includes neither a NAME nor a LIBRARY statement, ILINK32 assumes a NAME statement without a <ModuleName> parameter.

- **WINDOWSAPI** specifies a Windows executable, and is equivalent to the ILINK32 option **-aa**.
- **WINDOWCOMPAT** specifies a Windows-compatible character-mode executable, and is equivalent to the ILINK32 option **-ap**.

SECTIONS Statement

Lets you set attributes for one or more section in the image file. you can use this You can use this statement to override the default attributes for each different type of section.

```
SECTIONS<section_name> [CLASS '<ClassName>'] <attributes>
```

- **SECTIONS** marks the beginning of a list of section definitions.
- After the SECTIONS keyword, each section definition must be listed on a separate line. Note that the SECTIONS keyword can be on the same line as the first definition or on a preceding line. In addition, the .DEF file can contain one or more SECTIONS statements. The SEGMENTS keyword is supported as a synonym for SECTIONS.
- **<ClassName>** is case sensitive. The CLASS keyword is supported for compatibility but is ignored.
- **<Attributes>** is one or more of the following: EXECUTE, READ, SHARED, and WRITE.

SEGMENTS Statement

Defines the attributes of additional code and data sections. The SEGMENTS keyword is supported as a synonym for SECTIONS. The syntax is:

```
SEGMENTS

   <SegmentName> [CLASS '<ClassName>']

        [<MinAlloc>]
        [SHARED | NONSHARED]
        [PRELOAD | LOADONCALL]
```

- **<SegmentName>** is a character string that names the new segment. It can be any name, including the standard segment names _TEXT and _DATA, which represent the standard code and data segments.
- **<ClassName>** (optional) is the class name of the specified segment. If no class name is specified, ILINK32 uses the class name CODE.
- **<MinAlloc>** (optional) is an integer that specifies the minimum allocation size for the segment. ILINK32 ignores this value.
- **SHARED** means one copy of the segment is shared among all processes.
- **NONSHARED** (the default for .EXEs and .DLLs) means a copy of the segment is loaded for each process needing to use the data segment.
- **PRELOAD** means that the segment is loaded immediately.
- **LOADONCALL** means that the segment is loaded when it is accessed or called (this is ignored by ILINK32). The Resource Compiler may override the LOADONCALL option and preload segments instead.

STACKSIZE Statement

Defines the number of bytes the application needs for its local stack. An application uses the local stack whenever it makes function calls.

```
STACKSIZE <Reserve>[, <Commit>]
```

- **<Reserve>** can be a decimal or hex value, the default of which is 1MB. To help with backward (16-bit) compatibility, the linker uses the default value of 1MB if you specify in the .DEF file a reserve value less than 64K.
- **<Commit>** is a decimal or hex value. The commit size is optional, and if not specified defaults to 8K. The minimum commit size you can specify is 4K. In addition, the specified or default commit size must always be smaller or equal to the reserve size.

Reserved memory refers to the maximum amount of memory that can be allocated either in physical memory or in the paging file. In other words, reserved memory specifies the maximum possible stack size.

The operating system guarantees that the specified amount of memory will be reserved and, if necessary, allocated.

The meaning of committed memory varies among operating systems. In Windows NT, commited memory refers to the amount of physical memory allocated for the stack at application load/initialization time. Committed memory causes space to be allocated either in physical memory or in the paging file. A higher commit value saves time when the application needs more stack space, but increases memory requirements and possible startup time.

You can override any stack reserve or commit size specified in the .DEF file with the ILINK32 -S or -Sc command-line options. -S lets you specify a stack reserve size less than the 64K minimum allowed in the .DEF file.

Note: Do not use the STACKSIZE statement when compiling .DLLs.

STUB Statement

Appends a DOS executable file specified by FileName to the beginning of the module. The executable stub displays a warning message and terminates if the user attempts to run the executable stub in the wrong environment (running a Windows application under DOS, for example).

```
STUB '<FileName>'
```

- **<FileName>** is the name of the DOS executable file to be appended to the module. The name must have the DOS file name format. If the file named by FileName is not in the current irectory, ILINK32 searches for the file in the directories specified by the PATH environment variable.

C++Builder adds a built-in stub to the beginning of a Windows application unless a different stub is specified with the STUB statement. You should not use the STUB statement to include WINSTUB.EXE because the linker does this automatically.

SUBSYSTEM Statement

Lets you specify the Windows subsystem and subsystem version number for the application being linked.

```
SUBSYSTEM [<subsystem>,]<subsystemID>
```

- **<Subsystem>** (optional) can be any one of the following values: WINDOWS, WINDOWAPI, WINDOWCOMPAT. If you do not specify a subsystem, the linker defaults to a WINDOWS subsystem.
- **<SubsystemID>** must use the format d.d where d is a decimal number. For example, if you want to specify Windows 4.0, you could use either one of the following two SUBSYSTEM statements: SUBSYSTEM 4.0 SUBSYSTEM WINDOWS 4.0

You can override any SUBSYSTEM statement in a .DEF file using the -a and -V ILINK32 command-line options.

3.1.1.18 Using Precompiled Header Files

Precompiled header files can dramatically increase compilation speed by storing an image of the symbol table on disk in a file, then later reloading that file from disk instead of parsing all the header files again. Directly loading the symbol table from disk is much faster than parsing the text of header files, especially if several source files include the same header file.

To use precompiled header files, specify the various -H options in your BCC32 command.

Precompiled Header Options

Compiler Option	Description	Details
-H	Generate and use	When you enable this option, the compiler generates and uses precompiled headers. The default file name is BC32DEF.CSM for the command-line compiler.
-Hu	Use but do not generate	When you enable this option, the compiler uses preexisting precompiled header files; new precompiled header files are not generated.

H	Do not generate or use	When you enable this option, the compiler does not generate or use precompiled headers. Default = Do not generate or use (-H-)
-Hc	Cache precompiled headers	When you enable this option, the compiler caches the precompiled headers it generates. This is useful when you are precompiling more than one header file. To use this option, you must also enable the Generate and Use (-H) precompiled header option. Default = Off.
-He	Generate external type files (precompiled headers)	When you enable this option, the compiler generates a file or files that contain debug type information for all the symbols contained in the precompiled headers. The filenames end with .#xx extension, where xx is 00 for the first file generated and is incremented for each additional type-information file required. Using this option dramatically decreases the size of your .OBJ files, because debug type information is centralized and is not duplicated in each .OBJ file. Default = On.
-H=<filename>	Precompiled header filename	Use this option to specify the name of your precompiled header file. When you set this option, the compiler generates and uses the precompiled header file that you specify.

-Hh=<xxx> or -H\"<xxx>\"	Stop precompiling after header file option	This option terminates compiling the precompiled header after processing the file specified as xxx. You can use this option to reduce the disk space required for precompiled headers.
		The -Hh syntax is generally easier to use than the -H syntax. Examples:
		`-Hh=myhdr.h`
		`-H\"myhdr.h\"`
		`-Hh="C:\Program Files\myhdr.h"`
		`-H\"C:\Program Files\myhdr.h\"`
		When you use this option, the file you specify must be included from a source file for the compiler to generate a precompiled header file.
		You can also use #pragma hdrstop in your source file to specify when to stop the generation of precompiled headers.
		You cannot specify a header file that is included from another header file. For example, you cannot list a header included by windows.h because doing this would cause the precompiled header file to be closed before the compilation of windows.h was completed.

3.1.1.19 RLINK32.DLL, the Resource Linker (C++)

RLINK32.DLL is the resource linker that binds resources, in .RES file form, to an .EXE file, and marks the resulting .EXE file as a Windows executable. RLINK32.DLL also:

- Links the resources by fixing up string tables and message tables and then binding these linked resources into the executable.
- Is called by ILINK32 and is used for 32-bit resources.

3.1.1.20 TDUMP.EXE, the File Dumping Utility

TDUMP.EXE produces a file dump that shows the structure of a file.

TDUMP breaks apart a file structurally and uses the file's extension to determine the output display format. TDUMP recognizes many file formats, including .EXE, .OBJ, and .LIB files. If TDUMP doesn't recognize an extension, it produces a hexadecimal dump of the file. You can control the output format by using the TDUMP command-line options when you start the program.

TDUMP's ability to peek at a file's inner structure displays not only a file's contents, but also how a file is constructed. Moreover, because TDUMP verifies that a file's structure matches its extension, you can also use TDUMP to test file integrity.

Command Line Syntax

```
TDUMP [<options>] <inputfile> [<listfile>] [<options>]
```

- **<inputfile>** is the file whose structure you want to display (or “dump”).
- **<listfile>** is an optional output filename (you can also use the standard DOS redirection command (>).
- **<options>** are any of the TDUMP command line options.

To display command line help, enter:

```
tdump
```

You can use either the / or the - switch character. For example, these two commands are equivalent:

```
TDUMP -e1 -v demo.exe
TDUMP /el /v demo.exe
```

TDUMP Options

Option	Description
-a, -a7	TDUMP automatically adjusts its output display according to the file type. You can force a file to be displayed as ASCII by including the -a or -a7 option. -a produces an ASCII file display, which shows the offset and the contents in displayable ASCII characters. A character that is not displayable (like a control character) appears as a period. -a7 converts high-ASCII characters to their low-ASCII equivalents. This is useful if the file you are dumping sets high-ASCII characters as flags (WordStar files do this).
-b#	Allows you to display information beginning at a specified offset. For example, if you want a dump of MYFILE starting from offset 100, you would use: TDUMP -b100 MYFILE
-C	Causes TDUMP to dump information found in COFF format files (.OBJ and .LIB). This option is useful when linking with Microsoft .OBJ and .LIB files.
-d	Causes TDUMP to dump any CodeGear 32-bit debug information found in the .OBJ file. If you do not specify this option, TDUMP displays raw data only.

-e, -el, -er, -ex	All four options force TDUMP to display the file as an executable (.EXE) file. An .EXE file display consists of information contained within a file that is used by the operating system when loading a file. If symbolic debugging information is present (Turbo Debugger or Microsoft CodeView), TDUMP displays it. TDUMP displays information for DOS executable files, NEW style executable files (Microsoft Windows and OS/2 .EXEs and DLLs), Linear Executable files, and Portable Executable (PE) files used by Windows NT and Windows 95/98 and Windows 2000. • **-e** Displays file as Executable (EXE/DLL, DOS, Win16, OS/2, PE) • **-ea[:v]** Displays All Exports unsorted, or (:v) sort by RVA (default dumps only named exports, sorting on the name) a[:v] Displays All Exports unsorted, or (:v) sort by RVA (default dumps only named exports, sorting on the name) • **-ed** Disables EXE debug information • **-ee[=x]** Lists Exports only from EXE/DLL (optional x lists matches only) • **-el** Suppresses line numbers in the display • **-eiID** Includes only .EXE table ID (HDR, OBJ, FIX, NAM, ENT) • **-em[=x]** Lists Imports only from EXE/DLL (optional x lists matches only) • **-em.[x]** Lists Imported modules only from EXE/DLL (optional x search string) • **-ep** Disables EXE PE header display • **-er** Prevents the relocation table from displaying • **-ex** Prevents the display of New style executable information. This means TDUMP only displays information for the DOS "stub" program
-h	Displays the dump file in hexadecimal (hex) format. Hex format consists of a column of offset numbers, 16 columns of hex numbers, and their ASCII equivalents (a period appears where no displayable ASCII character occurs). If TDUMP doesn't recognize the input file's extension, it displays the file in hex format (unless an option is used to indicate another format).
-i	Specifies the debug table(s) to use.

-l, -li, -le	Displays the output file in library (.LIB) file format. A library file is a collection of object files (see the -o option for more on object files). The library file dump displays library-specific information, object files, and records in the object file.
	The **-li** option tells TDUMP to display a short form of "impdef" records when dumping import libraries. You can also specify a search string using the following syntax:
	`-li=<string>`
	For example, this command:
	`tdump –li=codeptr import32.lib`
	results in the following output:
	`Impdef:(ord) KERNEL32.0336=ISBADCODEPTR`
	This output shows that the function is exported by ordinal, whose ordinal value is 336 (decimal). In addition, the output displays the module and function name.
	If you enter the following command:
	`tdump –li=walk import32.lib`
	TDUMP displays:
	`Impdef:(name) KERNEL32.????=HEAPWALK`
	This shows the output of a function exported by name.

-le	Tells TDUMP to display a short form of the "expdef" records when dumping OBJ files. You can also specify a search string using the following syntax: -le=<string>
-m	Leaves C++ names occurring in object files, executable files, and Turbo Debugger symbolic information files in "mangled" format. This option is helpful in determining how the C++ compiler "mangles" a given function name and its arguments.

o, -oc, -oi, -ox	• **-o** displays the file as an object (.OBJ) file. An object file display contains descriptions of the command records that pass commands and data to the linker, telling it how to create an .EXE file. The display format shows each record and its associated data on a record-by-record basis. • **-oc** causes TDUMP to perform a cyclic redundancy test (CRC) on each encountered record. The display differs from the -o display only if an erroneous CRC check is encountered (the TDUMP CRC value differs from the record's CRC byte). • **-oi<id>** includes only specified record types in the object module dump. Replace <id> with the name of the record to be displayed. For instance: `TDUMP -oiPUBDEF MYMODULE.OBJ` produces an object module display for MYMODULE.OBJ that displays only the PUBDEF records. The **-ox** and **-oi** options are helpful in finding errors that occur during linking. By examining the spelling and case of the EXTDEF symbol and the PUBDEF symbol, you can resolve many linking problems. For instance, if you receive an "unresolved external" message from the linker, use TDUMP -oiEXTDEF to display the external definitions occurring in the module causing the error. Then, use TDUMP -oiPUBDEF on the module containing the public symbol the linker could not match. Another use for the -oi switch is to check the names and sizes of the segments generated in a particular module. For instance: TDUMP -oiSEGDEF MYMODULE.OBJ displays the names, attributes, and sizes of all of the segments in MYMODULE. **Note:** To get a list of record types for -oi and -ox, use the command line options **-oi?** and **-ox?**.
-r	Causes TDUMP to display raw data.
-R	Causes TDUMP to dump relocation tables from 32-bit PE (Win32) format images. The default is to suppress these dumps.

-s,
-su,
-s[xx]
	Tells TDUMP to display strings. By default -s displays all strings in a given file. You can specify a string, or part of a string, using the following syntax:
	`-s=<string>`
	For example, the command:
	`TDUMP -s=black GoGame.exe`
	results in the following output of all strings containing 'black':
	56840: IDI_BLACK
	81965: Capture Black
	85038: black.bmp
	The optional string argument is case insensitive. To specify several words of a string, use quotes. For example:
	`TDUMP -s="game of go" GoGame.exe`
	The -su option is used in the same manner, with an optional string argument, and tells TDUMP to display Unix-style strings, meaning with no offset.
	For example, the command:
	`TDUMP -su=black GoGame.exe`
	results in the following output:
	IDI_BLACK
	Capture Black
	black.bmp
	For the -s[xx] switch, xx can be:
	• **#** - minimum string length to look for (default: 4)
	• **b#** - Beginning file offset (-b# is the same as -sb#)
	• **e#** - Ending file offset
	• **f** - Format (wrap) long strings
	• **s** - Search string with case sensitivity (default: no)
	• **u** - unix format: no offset (or decimal offsets, -h for hex)
	• **=x** - search string = x

-um	Displays mangled names as unmangled. You do not need to reformat the text to edit out only the mangled names before using this option. You can pass output that has mangled names anywhere in the text, and only the mangled names will be affected.
-v	Verbose display. If used with an .OBJ or .LIB file, TDUMP produces a hexadecimal dump of the record's contents without any comments about the records. If you use TDUMP on a Turbo Debugger symbol table, it displays the information tables in the order in which it encounters them. TDUMP doesn't combine information from several tables to give a more meaningful display on a per-module basis.
-x	Specifies the debug table(s) to exclude.

3.1.1.21 TLIB.EXE, the Library Manager

TLIB is a utility that manages libraries of .OBJ (object module) files. A library is a convenient way to deal with a collection of object modules as a unit.

The libraries included with the CodeGear C++ compiler were built with TLIB. You can use TLIB to build your own libraries, or to modify the CodeGear C++ libraries, your libraries, libraries furnished by other programmers, or commercial libraries you've purchased.

When TLIB modifies an existing library, TLIB creates a copy of the original library and gives it a .BAK extension.

You can use TLIB to:

- Create a new library from a group of object modules.
- Add object modules or other libraries to an existing library.
- Remove object modules from an existing library.
- Replace object modules from an existing library.
- Extract object modules from an existing library.
- List the contents of a new or existing library.

TLIB can also create (and include in the library file) an extended dictionary, which can be used to speed up linking.

Although TLIB is not essential for creating executable programs with the CodeGear C++ compiler, it is a useful programming productivity tool that can be indispensable for large development projects.

Command Line Syntax

```
TLIB <libname> [<options>] [<operations>] [@<respfile>] [, <listfile>]
```

To display command line help, enter:

```
tlib
```

Element	Description
<libname>	The DOS path name of the library you want to create or manage. Every TLIB command must be given a libname. Wildcards are not allowed. TLIB assumes an extension of .LIB if none is given. Use only the .LIB extension because both BCC32 and the IDE require the .LIB extension in order to recognize library files. Note: If the named library does not exist and there are add operations, TLIB creates the library.
<options>	TLIB accepts five general options (C, L, P, O, and 8) as well as five default action options (a, d, e, u, and x). See the headings immediately following this table for details about the TLIB <options> and about the default action options.
<operations>	Describes the actions you want TLIB to do and consists of a sequence of two-character operation codes. If you only want to examine the contents of the library, do not give any operations. For more information, see the heading later in this topic.
@<respfile>	The path and name of the response file you want to include. You can specify more than one response file. For more details, see the heading later in this topic.
<listfile>	The name of the text file that TLIB will produce to hold a listing of the library contents. The listfile name (if given), must be preceded by a comma. No listing is produced if you don't give a file name. The listing is an alphabetical list of each module. The entry for each module contains an alphabetical list of each public symbol defined in that module. The default extension for the listfile is .LST.

TLIB General Command Options

TLIB recognizes five <options>:

- /C (case-sensitive; see further information below)
- /l (produces a listing file on standard output)
- /P (page size; see further information below)
- /0 (zero; purges comment records)
- /8 (displays warnings and messages encoded as UTF8)

TLIB /C Option: Using Case-Sensitive Symbols in a Library

When you add a module to a library, TLIB maintains a dictionary of all public symbols defined in the modules of the library. All symbols in the library must be distinct. If you try to add a module to the library that duplicates a symbol, TLIB displays an error message and doesn't add the module.

Normally, when TLIB checks for duplicate symbols in the library, uppercase and lowercase letters are not treated differently (for example, the symbols lookup and LOOKUP are treated as duplicates). You can use the /C option to add a module to a library that includes symbols differing only in case.

Don't use /C if you plan to use the library with other linkers or let other people use the library.

TLIB normally rejects symbols that differ only in case because some linkers aren't case-sensitive. ILINK32 has no problem distinguishing uppercase and lowercase symbols. As long as you use your library only with ILINK32, you can use the TLIB /C option without any problems.

TLIB /P option: Setting the Page Size to Create a Large Library

The library page size determines the maximum combined size of all object modules in the library, which cannot exceed 65,536 pages. The default (and minimum) page size of 16 bytes allows a library of about 1 MB in size. To create a larger library, use the /P option to increase the page size. The page size must be a power of 2, and it cannot be smaller than 16 or larger than 32,768.

All modules in the library must start on a page boundary. For example, in a library with a page size of 32 (the lowest possible page size higher than the default 16), an average of 16 bytes will be lost per object module in padding. If you attempt to create a library that is too large for the given page size, TLIB will issue an error message and suggest that you use /P with the next available higher page size.

TLIB Default Action Options

The default action options allow you to specify an action or several actions that are used for every subsequent module that does not have an explicit command specified, or until a different action flag is set. Using the default action options enables you to specify modules in a TLIB command without having to prefix each module with a command or action symbol. The TLIB default action options perform actions similar to those performed by the TLIB operation flags described in **TLIB Operations List**.

TLIB Default Action Options

Symbol	Description
/a	Add the module to the library.
/d	Remove the module from the library.
/e	Extract the module without removing it.
/u	Replace the module in the library.
/x	Extract the module and remove it.

TLIB Operations List

The operation list describes the actions you want TLIB to do and consists of a sequence of operations given one after the other. Each operation consists of a one- or two-character action symbol followed by a file or module name.:

```
<symbol> modulename
```

You can put whitespace around either the action symbol or the file or module name, but not in the middle of a two-character action or in a name. You can put as many operations as you like on the command line, up to DOS's COMMAND.COM-imposed line-length limit of 127 characters. The order of the operations is not important. TLIB always applies the operations in a specific order:

To replace a module, remove it, then add the replacement module.

1. All extract operations are done first.
2. All remove operations are done next.
3. All add operations are done last.

TLIB finds the name of a module by stripping any drive, path, and extension information from the given file name.

Note that TLIB always assumes reasonable defaults. For example, to add a module that has an .OBJ extension from the current directory, you need to supply only the module name, not the path and .OBJ extension.

Wildcards are never allowed in file or module names.

TLIB recognizes three action symbols (*, +, -), which you can use singly or combined in pairs for a total of five distinct operations. The order of the characters is not important for operations that use a pair of characters.

To create a library, you add modules to a library that does not yet exist.

TLIB Action Symbols

Symbol	Name	Description
+	Add	TLIB adds the named file to the library. If the file has no extension, TLIB assumes an extension of .OBJ. If the file is itself a library (with a .LIB extension), then the operation adds all of the modules in the named library to the target library. If a module being added already exists, TLIB displays a message and does not add the new module.
—	Remove	TLIB removes the named module from the library. If the module does not exist in the library, TLIB displays a message. A remove operation needs only a module name. TLIB lets you enter a full path name with drive and extension included, but ignores everything except the module name.
*	Extract	TLIB creates the named file by copying the corresponding module from the library to the file. If the module does not exist, TLIB displays a message and does not create a file. If the named file already exists, it is overwritten. You can't directly rename modules in a library. To rename a module, extract and remove it, rename the file just created, then add it back into the library.
—* or *—	Extract and remove	TLIB copies the named module from the library to the file. If the module does not exist, TLIB displays a message and does not create a file. If the named file already exists, it is overwritten. TLIB removes the file name and then removes it from the library.
—+ or +—	Replace	TLIB replaces the named module with the corresponding file.

Using TLIB Response Files

A response file is an ASCII text file that contains all or part of a TLIB command. Using TLIB response files, you can build TLIB commands that are longer than one command line. If you need to perform a large number of operations or perform operations several times, response files can make your job easier.

Response files can:

- Contain more than one line of text; use the ampersand character (&) at the end of a line to indicate that another line follows.
- Include a partial list of commands. You can combine options from the the command line with options in a response file.
- Be used with other response files in a single TLIB command line.

TLIB Examples

These simple examples demonstrate some of the different things you can do with TLIB:

Example 1

To create a library named MYLIB.LIB with modules X.OBJ, Y.OBJ, and Z.OBJ, type:

```
tlib mylib +x +y +z
```

Example 2

To create a library named MYLIB.LIB and get a listing in MYLIB.LST too, type:

```
tlib mylib +x +y +z, mylib.lst
```

Example 3

To get a listing in CS.LST of an existing library CS.LIB, type:

```
tlib cs, cs.lst
```

Example 4

To replace module X.OBJ with a new copy, add A.OBJ and delete Z.OBJ from MYLIB.LIB, type:

```
tlib mylib -+x +a -z
```

Example 5

To extract module Y.OBJ from MYLIB.LIB and get a listing in MYLIB.LST, type:

```
tlib mylib *y, mylib.lst
```

Example 6

To create a new library named ALPHA, with modules A.OBJ, B.OBJ, ..., G.OBJ using a response file:

1. First create a text file, ALPHA.RSP, with: `+a.obj +b.obj +c.obj & +d.obj +e.obj +f.obj & +g.obj`
2. Then use the TLIB command, which produces a listing file named ALPHA.LST: `tlib alpha @alpha.rsp, alpha.lst`

Example 7

To update modules Y.OBJ and Z.OBJ and delete modules A.OBJ and B.OBJ from MYLIB.LIB:

```
tlib mylib /u Y.obj Z.obj /d A.obj B.obj
```

3.1.1.22 Using TOUCH.EXE

TOUCH.EXE updates a file's date stamp so that it reflects your system's current time and date.

Command Line Syntax

```
touch [<options>] <filename> [<filename>...]
```

If TOUCH cannot find a file that matches the name you specify, it creates a zero-length file with the correct date stamp. To suppress automatic file creation, use the -c option.

Because TOUCH is a 32-bit executable, it accepts long file names. In addition, you can use file names that contain the wildcard characters * and ? to "touch" more than a single file at a time. Use the -s option to update matching files in all subdirectories.

Before you use TOUCH, make sure your system's internal clock is set correctly.

TOUCH Options

TOUCH.EXE supports several command line options.

TOUCH Options

Option	Description
-c	Don't generate file if it doesn't already exist.
-d<mm>-<dd>-<yy>	Sets the date of the file to the specified date.
-r<filename>	Sets the time and date of file to match those of <filename>.
-h	Displays help information (same as typing TOUCH without options or filenames.

-s	Recurses through subdirectories.
t<hh>:<mm>:<ss>-	Sets the time of the file to the specified time.
-v	Verbose mode. Shows each file that has been TOUCHed.

Using MAKE (see page 183)

3.1.1.23 TRIGRAPH

Trigraphs are three-character sequences that replace certain characters used in the C language that are not available on some keyboards. Translating trigraphs in the compiler would slow compilation down considerably, so CodeGear C++ provides a filter named TRIGRAPH.EXE to handle trigraph sequences.

Command Line Syntax

```
trigraph [-u] <filename> [...]
```

TRIGRAPH Options

TRIGRAPH has three command options:

- **-nXXX** writes output files to the directory named in XXX.
- **-u** means to Undo insert trigraphs.
- **-xXXX** creates output files with the extension XXX.

The following table shows the trigraph sequences the TRIGRAPH recognizes:

TRIGRAPH Character Sequences

The following table shows the trigraph sequences the TRIGRAPH recognizes:

Trigraph	Character
??=	#
??(	[
??)	]
??/	\
??'	^
??<	{
??>	}
??-	~

3.1.1.24 RC.EXE, the Microsoft SDK Resource Compiler

RC is the command-line version of the standard Microsoft SDK resource compiler. It accepts a resource script file (.RC) as input and produces a resource object file (.RES) as output.

Both C++Builder 2009 and Delphi 2009 give you a choice of resource compilers. On the **Project ▸ Options ▸ Resource Compiler** dialog box, you can select either of the following:

- BRCC32.exe, the CodeGear resource compiler

- RC.exe, the Microsoft platform SDK Resource Compiler

RC supports Unicode characters in resource files and file names, as well as new Vista resource types such as icons with alpha channel.

The actual filename of the RC compiler in the RAD Studio environment is ERC.exe.

Differences Between BRCC32 and RC

If you choose to use RC, several differences between BRCC32 and RC need to be addressed in existing .RC files, as follows:

- To use Windows types or constants with RC, you need to explicitly `#include <winresrc.h>` for both C++ and Delphi.
- RC does not handle image data inline as BRCC32 does. To use an image with RC, you need to save the image and refer to the image inline.
- RC handles line continution differently than BRCC32. The simplest change is to combine strings with embedded newlines (\n).
- For RC, the order of command elements requires that all command options must come first, before the name of the resource file.
- RC does not allow trailing commas after the string in a STRINGLIST.
- RC treats strings as C-style strings. This means that you need to do either of the following:
- Escape a single backslash (\) in filenames by using a double backslash (\\).
- Use a forward slash (/) in place of a single backslash (\).
- For RC, specifying `#include <dirname>` does not search the current directory. To search the current directory, use `#include "dirname"`.
- To embed a double-quote character in a string, use two consecutive double-quote characters ("") instead of using the backslash escape character.
- RCDATA and byte values are handled differently. For example:
- BRCC32 treats '11 aa 22 bb' as a string of bytes.
- For RC, you would need to specify 0xaa11 0xbb22.

3.1.1.25 WSDLIMP.EXE, the Command Line WSDL Import Tool

WSDLIMP generates code to represent the types and APIs that a WSDL document defines. This code can be used to write client applications that call on the Web Service that the WSDL (Web Services Description Language) document describes. If you want to write a server that implements the Web Service, one of the command line options tells the importer to generate implementation classes that you can then complete by filling in the bodies of the generated methods.

Note: WSDLIMP ignores any definitions in the WSDL document for which it can't generate code. That is, it can only import Web Services that use SOAP or document literal encoding.

```
Borland WSDLIMP Version 2.3 - $Rev: 16699 $
Copyright (c) 2008 Borland Software Corporation
Usage: WSDLIMP [options] <WSDL[File|URL]|UDDI BindingKey>
```

```
Code Generation Options:
 -C   Generate C++ code                    -P   Generate Pascal code
                        [ -option{+|-} default shown ]
 -Oa- Process optional/nillable elements  -Op+ Process inc/imported schemas
 -Od+ Generate Complex Type Destructors   -Oq- Quiet mode (Suppress Headers)
 -Of- Process Faults                      -Og- Use OLE GUIDs for interface
 -Oi- Ignore Schema errors                -Os- Generate Server skeleton code
 -Ok- Map pure collections to classes     -Ot- Output unused types
 -Ol- Generate Literal types              -Ou+ Unwrap Literal Parameters
 -Om- Allow out parameters                -Ov+ Verbose Info. in file
 -On- Declare Types in Namespace          -Ow+ Map strings to WideStrings
 -Oo+ One out param becomes return        -Ox+ Strong class Aliases
Other options:
 -D<path> Output directory path           -=+ Output filename after'=' in URL
 -U<url of UDDI Registry> UDDI Registry [NOTE: input must be UDDI bindingkey(s)

  @<Resp> Response file with list of WSDL|UDDIBindingKey to import

Proxy/Server Authentication:
-user:userName -pass:Password [-proxy:Proxy]
```

WSDLIMP.EXE imports a WSDL document, generating the code that lets your application call on the Web Service that the WSDL document describes. This is the command-line version of the Web Services importer, which is available on the Web Services tab of the new items dialog.

You can configure the output using the WSDLIMP command-line options when you start the program. These options let you specify whether the importer generates Object Pascal or C++ code, whether you want to generate implementation classes because you are writing a server, and how to handle various types of definitions in the WSDL document.

WSDLIMP Command Line Syntax

The command-line syntax for WSDLIMP is:

```
WSDLIMP [<options>] <Inputfile|URL>
```

<Inputfile> is a physical WSDL document to import.

<URL> is the URL for accessing a WSDL document that is published on the Web.

<options> stand for any of the WSDLIMP command-line options.

WSDLIMP Command Line Options

The following table lists the command-line options for WSDLIMP:

Options	Description
-C	Generate C++ code to represent the definitions in the WSDL file. You must use either this option or the –P option, but not both.
-P	Generate Object Pascal code to represent the definitions in the WSDL file. You must use either this option or the –C option, but not both.
-S	Generate implementation classes for the APIs that the WSDL document defines. This option is used when you want to write a server that implements the Web Service that the WSDL document describes.
-Oa	When the importer encounters a type that maps to a class with no members, change the imported code to an array. This option exists because in some cases when the WSDL document does not make consistent use of schema definitions, the importer has problems importing array types, which results in a type that is represented by a class with no members. This option is always safe to use unless the WSDL document describes a Web Service that uses document literal encoding. Document literal encoding can also give rise to an empty class when a method has no return value.
-Oi	Ignore ill-formed schemas when importing the WSDL document and attempt to import the Web Service anyway. This allows the importer to handle cases where the WSDL document is not completely well-formed but the intent is clear.

-Oo	Treat methods with a single output parameter as functions, mapping the single output parameter to the return value.
-Oq	Do not generate a header comment at the top of each generated file. The header comments indicate what options were used, list any warnings about the generated code, and so on.
-Oi	Generate type definitions for the two types that represent the input and output of a call when the Web Service uses document literal encoding. This option is only used with the –Ou+ option. When you do not specify –Ou+, the two type definitions are always generated.
-Ou+	Unwind the literal parameters of document literal encoding to generate method calls. When this option is selected, the importer converts the two types that
-Ov	Unwind the literal parameters of document literal encoding to generate method calls. When this option is selected, the importer converts the two types that
-Ov	Generate code comments (verbose information).
-R:<namelist>	Map strings in the WSDL document to the WideString type. WideStrings are more robust, because they can handle extended characters, but they are not as efficient as using AnsiStrings (the default).
-D<path>	Specifies the directory where WSDLIMP writes the files that it generates.
@<path>	Specifies a text file where each line lists a URL or WSDL file to import. You can optionally add '=OutputFileName' after the URL or file name to specify where to place the generated code for each imported WSDL document.

3.1.2 C++ Compiler Errors And Warnings (C++)

This section describes the RAD Studio C++ compiler error and warning messages.

Topics

Name	Description
E2066: Invalid MOM inheritance (C++) (see page 256)	The compiler issues this error if the currently compiled class doesn't have the same MOM (Microsoft Object Model) related flags set as its direct parent. This compiler error message is deprecated.
E2525: You must define _PCH_STATIC_CONST before including xstring to use this feature (C++) (see page 257)	You attempted to use a feature defined in xstring, part of the Dinkumware standard C++ library. The C++ compiler could not generate a precompiled header because there is a constant (defined in xstring) in the header. If you want to include xstring, you should first set the define _PCH_STATIC_CONST.
E2526: Property 'name' uses another property as getter/setter; Not allowed (C++) (see page 257)	Properties typically have both a getter and a setter, but a property cannot serve as either the getter or setter of another property.
E2008: Published property access functions must use __fastcall calling convention (C++) (see page 257)	The calling convention for access functions of a property (read, write, and stored) declared in a __published section must be __fastcall. This also applies to hoisted properties.
E2122: Function call terminated by unhandled exception 'value' at address 'addr' (C++) (see page 257)	This message is emitted when an expression you are evaluating while debugging includes a function call that terminates with an unhandled exception. For example, if in the debugger's evaluate dialog, you request an evaluation of the expression foo()+1 and the execution of the function foo() causes a GP fault, this evaluation produces the above error message. You may also see this message in the watches window because it also displays the results of evaluating an expression.
E2506: Explicit specialization of 'specifier' is ambiguous: must specify template arguments (C++) (see page 257)	In the following code, explicit template arguments are necessary:

E2483: Array dimension 'specifier' could not be determined (C++) (see page 258)	If, during instantiation of a type, an array dimension cannot be computed—usually this is due to some other error which would be reported—then this error will result. For example, if an array dimension is dependent upon a template parameter but an error occurs while it is being parsed and the template argument being substituted does not yield a legal constant expression, this error is displayed.
E2509: Value out of range (C++) (see page 258)	The inline assembler has detected a numeric overflow in one of your expressions. Make sure all of your numbers can fit in 32 bits.
E2510: Operand size mismatch (C++) (see page 258)	Help is not available for this item.
E2050: __declspec(delphireturn) class 'class' must have exactly one data member (C++) (see page 258)	This is an internal compiler error. A class marked as a delphireturn class has more than one non-static data member.
E2530: Unrecognized option, or no help available (C++) (see page 258)	You have entered a command element that the C++ compiler cannot parse, or the option you entered has no associated help. Try again.
E2527: Option 'name' cannot be set via 'name' (C++) (see page 258)	An attempt was made in a source file to set an option that cannot be set after either parsing or compiling of the file starts. Instead, set this option on the command line or in a `.cfg` file. For example, if a source file contains a `#pragma option push –v`, you need to remove the push or set /unset this option either on the command line or in a `.cfg` file.
E2528: Option 'name' must be set before compilation begins (C++) (see page 258)	An attempt was made in a source file to set an option that must be set before compiling starts. Instead, set this option on the command line, in a `.cfg` file, or at the top of the source file before the line `int foo();` .
E2074: Value after -g or -j should be between 0 and 255 inclusive (C++) (see page 259)	Both the -g and the -j command line options can be followed by an optional number. The compiler expects this number to be between 0 and 255 inclusive.
E2492: Properties may only be assigned using a simple statement, e.g. \"prop = value;\" (C++) (see page 259)	Assignments to properties should be made in simple assignment statements. If property assignments could become Lvalues, which happens when property assignments are embedded in larger statements, the getter is called to create the Lvalue, with all the side effects that getter causes. The compiler allows only one call to either the getter or the setter in a statement. For example:
E2505: Explicit instantiation requires an elaborated type specifier (i.e.,"class foo<int>") (C++) (see page 259)	The following code is illegal:
E2100: Invalid template declarator list (C++) (see page 259)	It is illegal for a declarator list to follow a template class declaration. For example:
E2102: Cannot use template 'template' without specifying specialization parameters (C++) (see page 260)	The generic form of a template must be referenced using specialization parameters. For example, for a template class named foo, taking two template parameters, then a legal reference might have the form
E2107: Invalid use of template 'template' (C++) (see page 260)	This error results when attempting to use a template template parameter in any way other than to reference a template specialization, or to pass that parameter in turn as a template template argument to another template. For example:
E2105: 'template' qualifier must specify a member template name (C++) (see page 260)	When parsing code that depends in some way upon a template parameter, it is sometimes impossible to know whether a member name will resolve to a template function name, or a regular parameter. In the following code, a 'template' qualifier is required in order to know if the '<' (less-then) operator should be parsed as the beginning character of a template argument list, or as a regular less-than operator:
E2066: Information not available (C++) (see page 261)	Help is not available for this item.
E2471: pragma checkoption failed: options are not as expected (C++) (see page 261)	You can use #pragma checkoption to check that certain switches are in the state that you expect. If #pragma checkoption detects that a switch is not in the expected state, the compiler displays this error. You can use the following syntax:
E2504: 'dynamic' can only be used with non-template member functions (C++) (see page 261)	You tried to use dynamic with a template member function. Dynamic functions are allowed for classes derived from TObject. Dynamic functions occupy a slot in every object that defines them, not in any descendants. That is, dynamic functions are virtual functions stored in sparse virtual tables. If you call a dynamic function, and that function is not defined in your object, the virtual tables of its ancestors are searched until the function is found.
E2191: '__far16' may only be used with '__pascal' or '__cdecl' (C++) (see page 261)	This is an internal compiler error. The compiler emits this message if the keyword __far16 is mixed with one of the keywords __pascal or __cdecl, all in the same declaration.
E2199: Template friend function 'function' must be previously declared (C++) (see page 262)	Not used

E2502: Error resolving #import: problem (C++) (see page 262)	Where `problem` can be any of the following relating to problems with the various attributes of #include (see page 692): unexpected import directive value attribute 'attribute'A value was supplied for the indicated attribute. None was expected. missing ')' in import directive attribute 'attribute'The value for the indicated attribute was incorrectly specified : a closing parenthesis is missing. unrecognized import directive attribute 'attribute'The indicated token is not a legitimate attribute for the #import directive. invalid values for raw_property_prefixes attributeThe values for the raw_property_prefixes attribute were incorrectly specified. unexpected duplicate property 'property'The indicated #import attribute was specified more than once -- this is an... more (see page 262)
E2501: Unable to open import file 'filename' (C++) (see page 262)	This error occurs when you use:
E2494: Unrecognized __declspec modifier (C++) (see page 262)	A _declspec modifier was given that is not valid.
E2493: Invalid GUID string (C++) (see page 263)	The GUID string does not have the form of a Globally Unique Identifier.
E2499: Invalid __declspec(uuid(GuidString)) format (C++) (see page 263)	This error happens when you used the wrong format to define your GuidString. GUIDs are defined for structs in the following way:
E2496: Invalid call to uuidof(struct type|variable) (C++) (see page 263)	The uuidof operator was given an incorrect argument.
E2511: Unterminated macro argument (C++) (see page 263)	A macro argument that was started on the line listed has not been properly terminated
E2489: Maximum option context replay depth exceeded; check for recursion (C++) (see page 263)	If this error is triggered, it means that recursive template instantiation has gone too deep. Check for compile-time recursion in your program, and limit it to no more than 256 levels.
E2488: Maximum token reply depth exceeded; check for recursion (C++) (see page 263)	If this error is triggered, it means that recursive template instantiation has gone too deep. Check for compile-time recursion in your program, and limit it to no more than 256 levels.
E2491: Maximum VIRDEF count exceeded; check for recursion (C++) (see page 263)	Too many VIRDEF symbols were allocated. The compiler imposes a limit to the number of VIRDEFs allowed per translation unit. Currently this limit is in the order of 16384 VIRDEFs. One way this could happen is if a program has more than 16384 functions.
E2230: In-line data member initialization requires an integral constant expression (C++) (see page 264)	Static const class members, which are initialized in the body of the class, have to be initialized with a constant expression of integral type.
E2241: VCL style classes need virtual destructors (C++) (see page 264)	Destructors defined in VCL style classes have to be virtual.
E2524: Anonymous structs/unions not allowed to have anonymous members in C++ (C++) (see page 264)	The C++ compiler requires that the members of an anonymous struct or union be named.
E2246: x is not abstract public single inheritance class hierarchy with no data (C++) (see page 264)	Internal compiler error. In some cases, the compiler will enforce restrictions on a class hierarchy. In this case, the restrictions would be that all classes are abstract classes, and all classes only have one parent.
E2249: = expected (C++) (see page 264)	The compiler expected an equal sign in the position where the error was reported but there was none. This is usually a syntax error or typo.
E2267: First base must be VCL class (C++) (see page 264)	Internal compiler error. In some cases, the compiler will enforce restrictions on a class hierarchy. In this case, the restrictions would be that the first parent of a class is a Delphi style class.
E2472: Cannot declare a member function via instantiation (C++) (see page 265)	If a declaration within a template class acquires a function type through a type dependent on a template-parameter and this results in a declaration that does not use the syntactic form of a function declarator to have function type, the program is ill-formed. For example:
E2515: Cannot explicitly specialize a member of a generic template class (C++) (see page 265)	You are trying to make a generic template into a specialized member. For example, the following code is illegal:
E2474: 'function' cannot be declared as static or inline (C++) (see page 265)	You attempted to declare a symbol as static or inline and this type of symbol cannot be defined as static or inline. Certain functions, like 'main' and 'WinMain' cannot be declared static or inline. 'main' is the entrypoint of console applications, and 'WinMain' is the entry point of Windows applications. For example, this error is displayed in the following cases:
E2498: Need previously defined struct GUID (C++) (see page 266)	This happens when you use the __uuidof operator without including a header that defines the GUID struct. So the following program code would display this error:
E2295: Too many candidate template specializations from 'specifier' (C++) (see page 266)	When reference a class template specialization, it is possible that more than one possible candidate might result from a single reference. This can only really happen among class partial specializations, when more than one partial specialization is contending for a possible match:
E2475: 'function' cannot be a template function (C++) (see page 266)	Certain functions, like 'main' and 'WinMain' cannot be declared as a template function. 'main' is the entrypoint of console applications, and 'WinMain' is the entry point of Windows applications. For example:

E2299: Cannot generate template specialization from 'specifier' (C++) (see page 267)	This error will result if an attempt is made to reference a template class or function in a manner which yields no possible candidate specializations. For example:
E2300: Could not generate a specialization matching type for 'specifier' (C++) (see page 267)	This error is no longer generated by the compiler.
E2497: No GUID associated with type:'type' (C++) (see page 267)	A variable or type was used in a context requiring a GUID, but the type does not have a GUID associated with it. GUIDs are associated with types using _declspec (uuid(GUID)).
E2522: Non-const function 'function' called for const object (C++) (see page 267)	Data type mismatch resulting in an erroneous function call. The object of the call (a non-const function) should be a const object.
E2523: Non-volatile function 'name' called for volatile object (C++) (see page 267)	Data type mismatch. The error is the result of an erroneous function call. The object of the call (a non-volatile function) should be a volatile object.
E2513: Cannot emit RTTI for 'parameter' in 'function' (C++) (see page 267)	The compiler issues this error if it cannot generate RTTI information for the return type of a parameter. See Runtime type information for more information.
E2512: Cannot emit RTTI for return type of 'function' (C++) (see page 267)	The compiler issues this error if the it cannot generate RTTI information for the return type of a function. See Runtime type information for more information.
E2507: 'class' is not a direct base class of 'class' (C++) (see page 268)	The first type is not a direct base class of the second type. A direct base class refers to the immediate derivations of that class, and not the derivations of its subclasses.
E2529: Path 'path' exceeds maximum size of 'n' (C++) (see page 268)	In looking up include files, the C++ compiler has encountered a file whose path name contains more characters than are allowed in the Windows maximum. Rename the path to a shorter name.
E2495: Redefinition of uuid is not identical (C++) (see page 268)	GUID's attached to structs have to be the same across multiple declarations and definitions of the same struct. So the following example would cause this error:
E2500: __declspec(selectany) is only for initialized and externally visible variables (C++) (see page 268)	You cannot use __declspec(selectany) with static variables, unitialized variables, etc.
E2482: String constant expected (C++) (see page 268)	The compiler expected a string constant at this location but did not receive one. This error is no longer generated by the compiler.
E2481: Unexpected string constant (C++) (see page 268)	There are times when the compiler does not expect a string constant to appear in the source input. For example:
E2386: Cannot involve parameter 'parameter' in a complex partial specialization expression (C++) (see page 268)	When declaring or defining a template class partial specialization, it is illegal to involve any of the non-type template parameters in complex expressions. They may only be referenced by name. For example:
E2387: Partial specializations may not specialize dependent non-type parameters ('parameter') (C++) (see page 269)	A partial specialization may not use a template parameter in its specialization argument list which is dependent on another type parameter. For example:
E2388: Argument list of specialization cannot be identical to the parameter list of primary template (C++) (see page 269)	When declaring a partial specialization, its specialization argument list must differ in some way from its basic parameter list. For example: template<class T>
E2389: Mismatch in kind of substitution argument and template parameter 'parameter' (C++) (see page 269)	When referencing a template specialization, all type parameters must be satisfied using type arguments, all non-type parameters require non-type arguments, and all template template parameters require either a template name, or another template template argument. Mismatching these requirements in any way will trigger the above error. For example:
E2480: Cannot involve template parameters in complex partial specialization arguments (C++) (see page 269)	A partial specialization cannot reference other template parameters in a nonvalue argument expression, unless it is simply a direct reference to the template parameter. For example:
E2392: Template instance 'template' is already instantiated (C++) (see page 270)	There are two ways to trigger this error. If –A is enabled (ANSI compliant mode), then attempting to explicitly instantiate a template specialization which has already been instantiated (either implicitly or explicitly) will cause this error. Regardless of –A, attempting to explicitly specialize a template specialization which has already been either implicit or explicitly instantiated will always trigger this error. For example:
E2393: Cannot take the address of non-type, non-reference template parameter 'parameter' (C++) (see page 270)	A template parameter has no address, and is not associated with any real "object". Therefore, to take its address, or attempt to assign to it, has no meaning. For example:
E2399: Cannot reference template argument 'arg' in template class 'class' this way (C++) (see page 270)	The compiler no longer generates this error.
E2397: Template argument cannot have static or local linkage (C++) (see page 270)	Only integral constant expressions, and the address of global variables with external linkage, may be used as template arguments. For example:
E2485: Cannot use address of array element as non-type template argument (C++) (see page 271)	Non-type template arguments may only be of integral type, or the address of a global variable. They cannot be the address of an array element. For example:
E2402: Illegal base class type: formal type 'type' resolves to 'type' (C++) (see page 271)	When instantiating a template class definition, if it is found that a declared base class does not resolve to an accessible class type, this error will result. For example:
E2403: Dependent call specifier yields non-function 'name' (C++) (see page 271)	The compiler no longer generates this error.

E2404: Dependent type qualifier 'qualifier' has no member type named 'name' (C++) (see page 271)	If a template declaration references a member of a dependent type, it is only possible to alert the user to the non-existence of this member during type instantiation for a given set of template arguments. For example:
E2405: Dependent template reference 'identifier' yields non-template symbol (C++) (see page 271)	If a template specialization reference within a template declaration yields a reference to a non-template during type instantiation, the above error will result. For example:
E2406: Dependent type qualifier 'qualifier' is not a class or struct type (C++) (see page 272)	If a dependent name reference within a template declaration results in a non-struct member qualification at instantiation time, the above error will result. For example:
E2407: Dependent type qualifier 'qualifier' has no member symbol named 'name' (C++) (see page 272)	If a template declaration references a member of a dependent type, it is only possible to alert the user to the non-existence of this member during type instantiation for a given set of template arguments. For example:
E2408: Default values may be specified only in primary class template declarations (C++) (see page 272)	Template functions, and class partial specializations, may not use default expressions in their template parameter lists. Only primary template declarations may do this. For example:
E2409: Cannot find a valid specialization for 'specifier' (C++) (see page 272)	This error is no longer generated by the compiler.
E2410: Missing template parameters for friend template 'template' (C++) (see page 273)	If a friend template is declared, but no template parameters are specified, this error will result. For example:
E2486: Cannot use address of class member as non-type template argument (C++) (see page 273)	Non-type template arguments may only be of integral type, or the address of a global variable. They cannot be the address of a class member. For example:
E2411: Declaration of member function default parameters after a specialization has already been expanded (C++) (see page 273)	If a member function of a class template is declared, and then a specialization of that class implicitly instantiated, and later that member function defined with default parameters specified, the above error will result. For example:
E2412: Attempting to bind a member reference to a dependent type (C++) (see page 273)	The compiler no longer generates this error.
E2414: Destructors cannot be declared as template functions (C++) (see page 273)	Destructors cannot be templates. For example:
E2473: Invalid explicit specialization of 'specifier' (C++) (see page 274)	Attempting to explicitly specialize a static data member or any non-template will cause this error.
E2490: Specialization within template classes not yet implemented (C++) (see page 274)	Explicit and partial specialization of member template classes and functions within template classes and nested template classes, is not supported.
E2416: Invalid template function declaration (C++) (see page 274)	The compiler no longer generates this error.
E2417: Cannot specify template parameters in explicit specialization of 'specifier' (C++) (see page 274)	The compiler no longer generates this error.
E2418: Maximum instantiation depth exceeded; check for recursion (C++) (see page 274)	The compiler only supports 256 levels of instantiation before it will trigger this error. The main problem is in controlling stack depth, because the parser uses recursive functions to manage type instantiation. Here is an example that would produce such an error:
E2420: Explicit instantiation can only be used at global scope (C++) (see page 274)	Explicit instantiation cannot be specified at any level other than namespace or global scope. For example:
E2422: Argument kind mismatch in redeclaration of template parameter 'parameter' (C++) (see page 275)	If a template is declared at one point in the translation unit, and then redeclared with template parameters of a different kind at another location, this error will result. For example:
E2423: Explicit specialization or instantiation of non-existing template 'template' (C++) (see page 275)	Attempting to explicit specialize or instantiate a template which does not exist is clearly illegal. For example:
E2479: Cannot have both a template class and function named 'name' (C++) (see page 275)	No other function or type may have the same name as a template class. For example:
E2484: The name of template class 'class' cannot be overloaded (C++) (see page 275)	Attempting to declare a function that overrides the name of a template class will cause this error. For example:
E2426: Explicit specialization of 'specifier' requires 'template<>' declaration (C++) (see page 275)	According to the standard, explicit specialization of any template now always require the "template<>" declarator syntax. For example:
E2487: Cannot specify default function arguments for explicit specializations (C++) (see page 276)	An explicit specialization of a function may not declare default function arguments. For example:
E2427: 'main' cannot be a template function (C++) (see page 276)	'main' cannot be declared as a template function. 'main' is the entry point of a console application, and it should be declared as a regular __cdecl function. This error message should not occur because it has been replaced with another one (E2475).
E2429: Not a valid partial specialization of 'specifier' (C++) (see page 276)	Internal compiler error.
E2430: Number of template parameters does not match in redeclaration of 'specifier' (C++) (see page 276)	If a template is redeclared with a different number of template parameters, this error will result. For example:
E2477: Too few template parameters were declared for template 'template' (C++) (see page 276)	If a member declaration or definition occurs outside of a template class, and that outer declaration uses a different number of template parameters than the parent class, this error will result. For example:
E2478: Too many template parameters were declared for template 'template' (C++) (see page 277)	If a member declaration or definition occurs outside of a template class, and that outer declaration uses a different number of template parameters than the parent class, this error will result. For example:

E2431: Non-type template parameters cannot be of floating point, class, or void type (C++) (see page 277)	Non-type template parameters are restricted as to what type they may be. Floating point, class and void types are illegal. For example:
E2434: Template declaration missing template parameters ('template<...>') (C++) (see page 277)	In a context where at least one template parameter is clearly required, if none are found this error will result. For example:
E2435: Too many template parameter sets were specified (C++) (see page 277)	If a member template is being defined outside of its parent class, and too many template parameter sets are declared, this error will result. For example:
E2436: Default type for template template argument 'arg' does not name a primary template class (C++) (see page 277)	If a template template parameter is to have a default type, that type must either be a generic template class name, or another template template parameter.
E2437: 'typename' should be followed by a qualified, dependent type name (C++) (see page 278)	Whenever the "typename" keyword is used in a template declaration or definition, it should always name a dependent type. For example:
E2438: Template template arguments must name a class (C++) (see page 278)	A template template parameter must always declare a new class name. For example:
E2439: 'typename' is only allowed in template declarations (C++) (see page 278)	The "typename" keyword must only be used within template declarations and definitions.
E2440: Cannot generate specialization from 'specifier' because that type is not yet defined (C++) (see page 278)	The compiler no longer generates this error.
E2441: Instantiating 'specifier' (C++) (see page 278)	Whenever a compiler error occurs while instantiating a template type, the context of what was being instantiated at that point in time will be reported to the user, in order to aid in detection of the problem.
E2503: Missing or incorrect version of TypeLibImport.dll (C++) (see page 279)	This error occurs when the compiler is trying to access TypeLibImport.dll but it either can't find it, it was corrupted, or you have the wrong version of it installed on your computer. You can reinstall it from the product CD.
E2470: Need to include header <typeinfo> to use typeid (C++) (see page 279)	When you use the 'typeid' function, you have to include the <typeinfo> header, otherwise you will get syntax errors. For example, consider a test case with the following code:
E2514: Cannot (yet) use member overload resolution during template instantiation (C++) (see page 279)	You are trying to overload a member during template instantiation. You cannot have calls to overloaded constant functions within array bounds initializers, for example.
E2508: 'using' cannot refer to a template specialization (C++) (see page 279)	The `using` keyword cannot refer to a template specialization.
E2462: 'virtual' can only be used with non-template member functions (C++) (see page 279)	The 'virtual' keyword can only be applied to regular member functions, not to member template functions. Consider a test case with the following code:
W8086: Incorrect use of #pragma alias "aliasName"="substituteName" (C++) (see page 280)	The directive #pragma alias is used to tell the linker that two identifier names are equivalent. You must put the two names in quotes. You will receive this warning if you don't use pragma alias correctly. For example, the following two lines both generate this warning:
W8099: Static main is not treated as an entry point (C++) (see page 280)	The main function has been created as static, and as such cannot be used as a valid entry point. Consider:
W8093: Incorrect use of #pragma codeseg [seg_name] ["seg_class"] [group] (C++) (see page 280)	The #pragma codeseg directive can be used to set or reset the name, class, and group of a segment. You have to follow the exact syntax mentioned in the warning message, and all names are optional. So these are all legal:
W8094: Incorrect use of #pragma comment(<type> [,"string"]) (C++) (see page 280)	The directive #pragma comment can be used to emit linker comment records. In this message, <type> can be any of the following: • user • lib • exestr • linker The type should be there but the string is optional.
W8085: Function 'function' redefined as non-inline (C++) (see page 281)	This warning is used to indicate when a certain function, which has been declared inline in one location, is redefined in another location to be non-inline.
W8105: %s member '%s' in class without constructors (C++) (see page 281)	A class that contains constant or reference members (or both) must have at least one user-defined constructor. Otherwise, there would be no way to ever initialize such members.
W8095: Incorrect use of #pragma message("string") (C++) (see page 281)	You can use pragma message to emit a message to the command line or to the message window. You would get this warning if you use the incorrect syntax, so
W8098: Multi-character character constant (C++) (see page 281)	This warning is issued when the compiler detects a multi-character integer constant, such as:

W8096: Incorrect use of #pragma code_seg(["seg_name"[,"seg_class"]]) (C++) (see page 281)	Pragma code_seg is similar to pragma codeseg, but with this one you can only modify the name and the class of a code segment. If you use the wrong syntax, you get this warning. The following examples show the correct usage:
W8083: Pragma pack pop with no matching pack push (C++) (see page 282)	Each #pragma pack(pop) should have a matching preceding #pragma pack(push) in the same translation unit. Pairs of 'push' and 'pop' can be nested. For example:
W8097: Not all options can be restored at this time (C++) (see page 282)	Your program has a #pragma pop at a place where it can't restore options. For example:
W8084: Suggest parentheses to clarify precedence (C++) (see page 282)	This warning indicates that several operators used in one expression might cause confusion about the applicable operator precedence rules. The warning helps create code that is more easy to understand and potentially less ambiguous. For example, compile the following code using the `-w` command line option:
W8092: 'type' argument 'specifier' passed to 'function' is not an iterator: 'type' iterator required (C++) (see page 282)	An argument that is not an iterator is being used with an STL algorithm that requires an iterator.
W8087: 'operator::operator==' must be publicly visible to be contained by a 'type' (C++) (see page 283)	A type that is being used with an STL container has a private 'operator=='.
W8090: 'type::operator<' must be publicly visible to be used with 'type' (C++) (see page 283)	A type that is being used with an STL container has a private 'operator<'. The type you're trying to use must be made public.
W8089: 'type::operator<' must be publicly visible to be contained by a 'type' (C++) (see page 283)	The type that is being used for an STL container has a private 'operator<'. The type that is being contained (type::operator) must be a public type. For example, if you were trying to instantiate a class type "vector<blah>", the error would be:
W8091: 'type' argument 'specifier' passed to 'function' is a 'iterator category' iterator: 'iterator category' iterator required (C++) (see page 283)	An incorrect iterator category is being used with an STL algorithm.
W8076: Template instance 'specifier' is already instantiated (C++) (see page 283)	You are trying to explicitly instantiate a template that was already implicitly instantiated. If –A is not enabled and an attempt is made to explicitly instantiate a specialization which has already been either implicitly or explicitly instantiated, this error will result.
W8077: Explicitly specializing an explicitly specialized class member makes no sense (C++) (see page 283)	Internal error. This warning is no longer generated by the compiler. The following code is illegal:
Informational messages (C++) (see page 284)	The compiler displays status information while compiling if you have checked "Show general messages" on the Compiler page of the Project Options dialog box. Most of the messages are self-explanatory and state information about compiling and linking; for example:
E2196: Cannot take address of member function 'function' (C++) (see page 284)	An expression takes the address of a class member function, but this member function was not found in the program being debugged. The evaluator issues this message.
F1002: Unable to create output file 'filename' (C++) (see page 284)	This error occurs if the work disk is full or write protected. This error also occurs if the output directory does not exist. *Solutions* If the disk is full, try deleting unneeded files and restarting the compilation. If the disk is write-protected, move the source files to a writeable disk and restart the compilation.
F1003: Error directive: 'message' (C++) (see page 284)	This message is issued when an `#error` directive is processed in the source file. 'message' is the text of the `#error` directive.
F1004: Internal compiler error (C++) (see page 284)	An error occurred in the internal logic of the compiler. This error shouldn't occur in practice, but is generated in the event that a more specific error message is not available.
F1006: Bad call of intrinsic function (C++) (see page 284)	You have used an intrinsic function without supplying a prototype. You may have supplied a prototype for an intrinsic function that was not what the compiler expected.
F1007: Irreducible expression tree (C++) (see page 285)	An expression on the indicated line of the source file caused the code generator to be unable to generate code. Avoid using the expression. Notify CodeGear if an expression consistently reproduces this error.
F1009: Unable to open input file 'filename' (C++) (see page 285)	This error occurs if the source file can't be found. Check the spelling of the name. Make sure the file is on the specified disk or directory. Verify that the proper directory paths are listed. If multiple paths are required, use a semicolon to separate them.

F1011: Register allocation failure (C++) (see page 285)	*Possible Causes* An expression on the indicated line of the source file was so complicated that the code generator could not generate code for it. *Solutions* Simplify the expression. If this does not solve the problem, avoid the expression. Notify CodeGear if an expression can consistently reproduce this error.
F1012: Compiler stack overflow (C++) (see page 285)	The compiler's stack has overflowed. This can be caused by a number of things, among them deeply nested statements in a function body (for example, if/else) or expressions with a large number of operands. You must simplify your code if this message occurs. Adding more memory to your system will not help.
F1013: Error writing output file (C++) (see page 285)	A DOS error that prevents the C++ IDE from writing an .OBJ, .EXE, or temporary file. *Solutions* Make sure that the Output directory in the Directories dialog box is a valid directory. Check that there is enough free disk space.
F1000: Compiler table limit exceeded (C++) (see page 285)	One of the compiler's internal tables overflowed. This usually means that the module being compiled contains too many function bodies. This limitation will not be solved by making more memory available to the compiler. You need to simplify the file being compiled.
F1005: Include files nested too deep (C++) (see page 286)	This message flags (directly or indirectly) recursive `#include` directives.
F1008: Out of memory (C++) (see page 286)	The total working storage is exhausted. This error can occur in the following circumstances: • Not enough virtual memory is available for compiling a particular file. In this case, shut down any other concurrent applications. You may also try to reconfigure your machine for more available virtual memory, or break up the source file being compiled into smaller separate components. You can also compile the file on a system with more available RAM. • The compiler has encountered an exceedingly complex or long expression at the line indicated and has insufficient reserves to parse it. Break the expression down into separate statements.... more (see page 286)
F1010: Unable to open 'filename' (C++) (see page 286)	This error occurs if the specified file can't be opened. Make sure the file is on the specified disk or directory. Verify the proper paths are listed. If multiple paths are required, use a semicolon to separate them.
E2000: 286/287 instructions not enabled (C++) (see page 286)	Use the -2 command-line compiler option to enable 286/287 opcodes. Be aware that the resulting code cannot be run on 8086- and 8088-based machines.
Abnormal program termination (C++) (see page 286)	The program called abort because there wasn't enough memory to execute. This message can be caused by memory overwrites.
E2009: Attempt to grant or reduce access to 'identifier' (C++) (see page 286)	A C++ derived class can modify the access rights of a base class member, but only by restoring it to the rights in the base class. It can't add or reduce access rights.
E2011: Illegal to take address of bit field (C++) (see page 286)	It is not legal to take the address of a bit field, although you can take the address of other kinds of fields.
E2010: Cannot add or subtract relocatable symbols (C++) (see page 287)	The only arithmetic operation that can be performed on a relocatable symbol in an assembler operand is addition or subtraction of a constant. Variables, procedures, functions, and labels are relocatable symbols.
E2013: 'function1' cannot be distinguished from 'function2' (C++) (see page 287)	The parameter type lists in the declarations of these two functions do not differ enough to tell them apart. Try changing the order of parameters or the type of a parameter in one declaration.

E2014: Member is ambiguous: 'member1' and 'member2' (C++) (see page 287)	You must qualify the member reference with the appropriate base class name. In C++ class 'class', member 'member' can be found in more than one base class, and it was not qualified to indicate which one you meant. This applies only in multiple inheritance, where the member name in each base class is not hidden by the same member name in a derived class on the same path. The C++ language rules require that this test for ambiguity be made before checking for access rights (private, protected, public). It is possible to get this message even though only one (or... more (see page 287)
E2015: Ambiguity between 'function1' and 'function2' (C++) (see page 287)	Both of the named overloaded functions could be used with the supplied parameters. This ambiguity is not allowed.
E2017: Ambiguous member name 'name' (C++) (see page 287)	Whenever a structure member name is used in inline assembly, such a name must be unique. (If it is defined in more than one structure, all of the definitions must agree as to its type and offset within the structures). In this case, an ambiguous member name has been used. For example:
E2019: 'identifier' cannot be declared in an anonymous union (C++) (see page 288)	The compiler found a declaration for a member function or static member in an anonymous union. Such unions can only contain data members.
E2020: Global anonymous union not static (C++) (see page 288)	In C++, a global anonymous union at the file level must be static.
E2022: Array size too large (C++) (see page 288)	The declared array is larger than 64K and the 'huge' keyword was not used. If you need an array of this size, either use the 'huge' modifier, like this:
E2024: Cannot modify a const object (C++) (see page 288)	This indicates an illegal operation on an object declared to be const, such as an assignment to the object.
E2025: Assignment to 'this' not allowed, use X::operator new instead (C++) (see page 288)	In early versions of C++, the only way to control allocation of class of objects was by assigning to the 'this' parameter inside a constructor. This practice is no longer allowed, because a better, safer, and more general technique is to define a member function operator new instead. For example:
E2026: Assembler statement too long (C++) (see page 288)	Inline assembly statements can't be longer than 480 bytes.
E2001: Constructors and destructors not allowed in __automated section (C++) (see page 289)	Only member function declarations are allowed in __automated sections.
E2002: Only __fastcall functions allowed in __automated section (C++) (see page 289)	The calling convention for functions declared in an __automated section must be __fastcall.
E2003: Data member definition not allowed in __automated section (C++) (see page 289)	Only member function declarations are allowed in __automated sections.
E2004: Only read or write clause allowed in property declaration in __automated section (C++) (see page 289)	Storage specifiers stored, default, and nodefault are not allowed in property declarations in __automated sections.
E2005: Redeclaration of property not allowed in __automated section (C++) (see page 290)	If you declare a property in an __automated section it has be a new declaration. Property hoisting is not allowed.
E2027: Must take address of a memory location (C++) (see page 290)	Your source file used the address-of operator (&) with an expression that can't be used that way; for example, a register variable.
E2028: operator -> must return a pointer or a class (C++) (see page 290)	The C++ operator -> function must be declared to either return a class or a pointer to a class (or struct or union). In either case, it must be something to which the -> operator can be applied.
E2029: 'identifier' must be a previously defined class or struct (C++) (see page 290)	You are attempting to declare 'identifier' to be a base class, but either it is not a class or it has not yet been fully defined. Correct the name or rearrange the declarations.
E2030: Misplaced break (C++) (see page 290)	The compiler encountered a break statement outside a switch or looping construct. You can only use break statements inside of switch statements or loops.
E2031: Cannot cast from 'type1' to 'type2' (C++) (see page 290)	A cast from type 'ident1' to type 'ident2' is not allowed. In C++, you cannot cast a member function pointer to a normal function pointer. For example:
E2033: Misplaced continue (C++) (see page 291)	The compiler encountered a continue statement outside a looping construct.
E2034: Cannot convert 'type1' to 'type2' (C++) (see page 291)	An assignment, initialization, or expression requires the specified type conversion to be performed, but the conversion is not legal. In C++, the compiler will convert one function pointer to another only if the signature for the functions are the same. Signature refers to the arguments and return type of the function. For example:
E2036: Conversion operator cannot have a return type specification (C++) (see page 292)	This C++ type conversion member function specifies a return type different from the type itself. A declaration for conversion function operator can't specify any return type.

E2037: The constructor 'constructor' is not allowed (C++) (see page 292)	Constructors of the form
E2039: Misplaced decimal point (C++) (see page 292)	The compiler encountered a decimal point in a floating-point constant as part of the exponent.
E2041: Incorrect use of default (C++) (see page 292)	The compiler found no colon after the default keyword.
E2042: Declare operator delete (void*) or (void*, size_t) (C++) (see page 293)	*E2043 Declare operator delete[] (void*) or (void*, size_t)*Compiler error Declare the operator delete with one of the following: 1.A single void* parameter, or 2.A second parameter of type size_t If you use the second version, it will be used in preference to the first version. The global operator delete can only be declared using the single-parameter form.
E2044: operator delete must return void (C++) (see page 293)	*E2044 operator delete[] must return void*Compiler error This C++ overloaded operator delete was declared in some other way. Declare the operator delete with one of the following: 1.A single void* parameter, or 2.A second parameter of type size_t If you use the second version, it will be used in preference to the first version. The global operator delete can only be declared using the single-parameter form.
E2045: Destructor name must match the class name (C++) (see page 293)	In a C++ class, the tilde (~) introduces a declaration for the class destructor. The name of the destructor must be same as the class name. In your source file, the ~ preceded some other name.
E2048: Unknown preprocessor directive: 'identifier' (C++) (see page 293)	The compiler encountered a # character at the beginning of a line. The directive name that followed the # was not one of the following: • define (see page 690) • else (see page 688) • endif • if • ifdef (see page 688) • ifndef (see page 688) • include (see page 692) • line (see page 693) • pragma • undef (see page 692)
E2046: Bad file name format in include directive OR Bad file name format in line directive (C++) (see page 294)	Include and line directive file names must be surrounded by quotes ("filename.h") or angle brackets (<filename.h>). The file name was missing the opening quote or angle bracket. If a macro was used, the resulting expansion text is not surrounded by quote marks.
E2051: Invalid use of dot (C++) (see page 294)	An identifier must immediately follow a period operator (.). This is a rare message that can only occur in some specialized inline assembly statements. *Example*
E2053: Misplaced elif directive (C++) (see page 294)	The compiler encountered an `#elif` directive without any matching `#if`, `#ifdef`, or `#ifndef` directive.
E2054: Misplaced else (C++) (see page 294)	The compiler encountered an `else` statement without a matching if statement. *Possible Causes* • An extra "else" statement • An extra semicolon • Missing braces • Some syntax error in a previous "if" statement
E2055: Misplaced else directive (C++) (see page 294)	The compiler encountered an `#else` directive without any matching `#if`, `#ifdef`, or `#ifndef` directive.
E2056: Misplaced endif directive (C++) (see page 295)	The compiler encountered an `#endif` directive without any matching `#if`, `#ifdef`, or `#ifndef` directive.
E2059: Unknown language, must be C or C++ (C++) (see page 295)	In the C++ construction

E2060: Illegal use of floating point (C++) (see page 295)	Floating-point operands are not allowed in these operators • shift (SHL, SHR) • bitwise Boolean (AND, OR, XOR, NOT) • conditional (? :) • indirection (*) • certain others The compiler found a floating-point operand with one of these prohibited operators.
E2061: Friends must be functions or classes (C++) (see page 295)	A friend of a C++ class must be a function or another class.
E2062: Invalid indirection (C++) (see page 295)	The indirection operator (*) requires a pointer as the operand. *Example*
E2063: Illegal initialization (C++) (see page 296)	Initializations must be one of the following: • constant expressions • the address of a global extern or static variable plus or minus a constant
E2064: Cannot initialize 'type1' with 'type2' (C++) (see page 296)	You are attempting to initialize an object of type 'type1' with a value of type 'type2' which is not allowed. The rules for initialization are essentially the same as for assignment.
E2068: 'identifier' is not a non-static data member and can't be initialized here (C++) (see page 296)	Only data members can be initialized in the initializers of a constructor. This message means that the list includes a static member or function member. Static members must be initialized outside of the class, for example:
E2069: Illegal use of member pointer (C++) (see page 296)	Pointers to class members can only be passed as arguments to functions, or used with the following operators: • assignment operators • comparison operators • `.*` • `–>*` • `?:` conditional (ternary) operator • `&&` logical AND (see page 531) operator • `||` logical OR (see page 559) operator The compiler has encountered a member pointer being used with a different operator. In order to call a member function pointer, one must supply an instance of the class for it to call upon. For example:
E2071: operator new must have an initial parameter of type size_t (C++) (see page 297)	*E2071 Operator new[] must have an initial parameter of type size_t*Compiler error Operator new can be declared with an arbitrary number of parameters. It must always have at least one, the amount of space to allocate.
E2072: Operator new[] must return an object of type void (C++) (see page 297)	This C++ overloaded operator new was declared in some other way.
E2075: Incorrect 'type' option: option (C++) (see page 297)	An error has occurred in either the configuration file or a command-line option. The compiler may not have recognized the configuration file parameter as legal; check for a preceding hyphen (-), or the compiler may not have recognized the command-line parameter as legal. This error can also occur if you use a `#pragma` option in your code with an invalid option.

E2076: Overloadable operator expected (C++) (see page 297)	Almost all C++ operators can be overloaded. These are the only ones that can't be overloaded: • the field-selection dot (.) • dot-star (.*) • double colon (::) • conditional expression (?:) The preprocessor operators (# and ##) are not C or C++ language operators and thus can't be overloaded. Other non-operator punctuation, such as semicolon (;), can't be overloaded.
E2080: 'function' must be declared with one parameter (C++) (see page 298)	This C++ operator function was incorrectly declared with more than one parameter.
E2077: 'operator' must be declared with one or no parameters (C++) (see page 298)	When operator ++ or operator -- is declared as a member function, it must be declared to take either: • No parameters (for the prefix version of the operator), or • One parameter of type int (for the postfix version)
E2079: 'function' must be declared with no parameters (C++) (see page 298)	This C++ operator function was incorrectly declared with parameters.
E2078: 'operator' must be declared with one or two parameters (C++) (see page 298)	When operator ++ or operator -- is declared as a non-member function, it must be declared to take either: • one parameter (for the prefix version of the operator), or • two parameters (for the postfix version)
E2081: 'function' must be declared with two parameters (C++) (see page 298)	This C++ operator function was incorrectly declared with other than two parameters.
E2082: 'identifier' must be a member function or have a parameter of class type (C++) (see page 298)	Most C++ operator functions must have an implicit or explicit parameter of class type. This operator function was declared outside a class and does not have an explicit parameter of class type.
E2083: Last parameter of 'operator' must have type 'int' (C++) (see page 299)	When a postfix operator ++ or operator -- is overloaded, the last parameter must be declared with the type int.
E2084: Parameter names are used only with a function body (C++) (see page 299)	When declaring a function (not defining it with a function body), you must use either empty parentheses or a function prototype. A list of parameter names only is not allowed. *Example declarations*
E2085: Invalid pointer addition (C++) (see page 299)	Your source file attempted to add two pointers together.
E2086: Illegal pointer subtraction (C++) (see page 299)	This is caused by attempting to subtract a pointer from a non-pointer.
E2087: Illegal use of pointer (C++) (see page 299)	Pointers can only be used with these operators: • addition(+) • subtraction(-) • assignment(=) • comparison(==) • indirection(*) • arrow(->) Your source file used a pointer with some other operator. *Example*
E2088: Bad syntax for pure function definition (C++) (see page 300)	Pure virtual functions are specified by appending "= 0" to the declaration, like this:

E2089: Identifier 'identifier' cannot have a type qualifier (C++) (see page 300)	A C++ qualifier class::identifier can't be applied here. A qualifier is not allowed on the following: • typedef names • function declarations (except definitions at the file level) • on local variables or parameters of functions • on a class member--except to use its own class as a qualifier (redundant but legal).
E2090: Qualifier 'identifier' is not a class or namespace name (C++) (see page 300)	The C++ qualifier in the construction qual::identifier is not the name of a struct or class.
E2092: Storage class 'storage class' is not allowed here (C++) (see page 300)	The given storage class is not allowed here. Probably two storage classes were specified, and only one can be given.
E2096: Illegal structure operation (C++) (see page 300)	Structures can only be used with dot (.), address-of (&) or assignment (=) operators, or be passed to or from a function as parameters. The compiler encountered a structure being used with some other operator.
E2104: Invalid use of template keyword (C++) (see page 300)	You can only use a template class name without specifying its actual arguments inside a template definition. Using a template class name without specifying its actual arguments outside a template definition is illegal.
E2108: Improper use of typedef 'identifier' (C++) (see page 301)	Your source file used a typedef symbol where a variable should appear in an expression. Check for the declaration of the symbol and possible misspellings.
E2109: Not an allowed type (C++) (see page 301)	Your source file declared some sort of forbidden type; for example, a function returning a function or array.
E2110: Incompatible type conversion (C++) (see page 301)	The cast requested can't be done.
E2113: Virtual function 'function1' conflicts with base class 'base' (C++) (see page 301)	A virtual function has the same argument types as one in a base class, but differs in one or more of the following: • Return type • Calling convention • Exception specification (throw list)
E2114: Multiple base classes require explicit class names (C++) (see page 301)	In a C++ class constructor, if there is more than one immediate base class, each base class constructor call in the constructor header must include the base class name.
E2115: Bit field too large (C++) (see page 301)	This error occurs when you supply a bit field with more than 16 bits.
E2116: Bit fields must contain at least one bit (C++) (see page 301)	You can't declare a named bit field to have 0 (or less than 0) bits. You can declare an unnamed bit field to have 0 bits. This is a convention used to force alignment of the following bit field to a byte boundary (or to a word boundary.
W8005: Bit fields must be signed or unsigned int (C++) (see page 302)	In ANSI C, bit fields may only be signed or unsigned int (not char or long, for example).
E2119: User break (C++) (see page 302)	You typed a Ctrl+Break while compiling in the IDE. (This is not an error, just a confirmation.)
E2111: Type 'typename' may not be defined here (C++) (see page 302)	Class and enumeration types may not be defined in a function return type, a function argument type, a conversion operator type, or the type specified in a cast. You must define the given type before using it in one of these contexts. `Note:` This error message is often the result of a missing semicolon (`;`) for a class declaration. You might want to verify that all the class declarations preceding the line on which the error occurred end with a semicolon.
E2121: Function call missing) (C++) (see page 302)	The function call argument list had some sort of syntax error, such as a missing or mismatched right parenthesis.
E2123: Class 'class' may not contain pure functions (C++) (see page 302)	The class being declared cannot be abstract, and therefore it cannot contain any pure functions.
E2126: Case bypasses initialization of a local variable (C++) (see page 302)	In C++ it is illegal to bypass the initialization of a local variable. This error indicates a case label that can transfer control past this local variable.
E2127: Case statement missing : (C++) (see page 302)	A case statement must have a constant expression followed by a colon. The expression in the case statement either was missing a colon or had an extra symbol before the colon.

E2128: Case outside of switch (C++) (see page 302)	The compiler encountered a case statement outside a switch statement. This is often caused by mismatched braces.
E2129: Character constant too long (or empty) (C++) (see page 303)	Character constants can only be one or two characters long.
E2133: Unable to execute command 'command' (C++) (see page 303)	The linker or assembler cannot be found, or possibly the disk is bad.
E2134: Compound statement missing closing brace (C++) (see page 303)	The compiler reached the end of the source file and found no closing brace. This is most commonly caused by mismatched braces.
E2137: Destructor for 'class' required in conditional expression (C++) (see page 303)	If the compiler must create a temporary local variable in a conditional expression, it has no good place to call the destructor because the variable might or might not have been initialized. The temporary can be explicitly created, as with classname(val, val), or implicitly created by some other code. You should recast your code to eliminate this temporary value.
E2135: Constructor/Destructor cannot be declared 'const' or 'volatile' (C++) (see page 303)	A constructor or destructor has been declared as `const` or `volatile`. This is not allowed.
E2138: Conflicting type modifiers (C++) (see page 303)	This occurs when a declaration is given that includes more than one addressing modifier on a pointer or more than one language modifier for a function. Only one language modifier (for example, `__cdecl`, `__pascal`, or `__fastcall`) can be given for a function.
E2136: Constructor cannot have a return type specification (C++) (see page 303)	C++ constructors have an implicit return type used by the compiler, but you can't declare a return type or return a value.
E2038: Cannot declare or define 'identifier' here: wrong namespace (C++) (see page 304)	You tried to declare a template in an illegal place or a namespace member outside of its namespace.
E2154: Cannot define 'identifier' using a namespace alias (C++) (see page 304)	You cannot use a namespace alias to define a namespace member outside of its namespace.
E2421: Cannot use local type 'identifier' as template argument (C++) (see page 304)	A local type was used in an actual template type argument, which is illegal.
E2035: Conversions of class to itself or base class not allowed (C++) (see page 304)	You tried to define a conversion operator to the same class or a base class.
E2139: Declaration missing ; (C++) (see page 304)	Your source file contained a struct or union field declaration that was not followed by a semicolon. Check previous lines for a missing semicolon.
E2140: Declaration is not allowed here (C++) (see page 304)	Declarations can't be used as the control statement for while, for, do, if, or switch statements.
E2141: Declaration syntax error (C++) (see page 304)	Your source file contained a declaration that was missing a symbol or had an extra symbol added to it. Check for a missing semicolon or parenthesis on that line or on previous lines.
E2142: Base class 'class' contains dynamically dispatchable functions (C++) (see page 304)	This error occurs when a class containing a DDVT function attempts to inherit DDVT functions from multiple parent classes. Currently, dynamically dispatched virtual tables do not support the use of multiple inheritance.
E2143: Matching base class function 'function' has different dispatch number (C++) (see page 305)	If a DDVT function is declared in a derived class, the matching base class function must have the same dispatch number as the derived function.
E2144: Matching base class function 'function' is not dynamic (C++) (see page 305)	If a DDVT function is declared in a derived class, the matching base class function must also be dynamic.
E2145: Functions 'function1' and 'function2' both use the same dispatch number (C++) (see page 305)	This error indicates a dynamically dispatched virtual table (DDVT) problem.
E2146: Need an identifier to declare (C++) (see page 305)	In this context, an identifier was expected to complete the declaration. This might be a typedef with no name, or an extra semicolon at file level. In C++, it might be a class name improperly used as another kind of identifier.
E2147: 'identifier' cannot start a parameter declaration (C++) (see page 305)	An undefined 'identifier' was found at the start of an argument in a function declarator. Often the type name is misspelled or the type declaration is missing. This is usually caused by not including the appropriate header file.
E2150: Type mismatch in default argument value (C++) (see page 305)	The default parameter value given could not be converted to the type of the parameter. The message "Type mismatch in default argument value" is used when the parameter was not given a name. When compiling C++ programs, this message is always preceded by another message that explains the exact reason for the type mismatch. That other message is most often "Cannot convert 'type1' to 'type2'" but the mismatch could be due to another reason.
E2152: Default expression may not use local variables (C++) (see page 306)	A default argument expression is not allowed to use any local variables or other parameters.

E2153: Define directive needs an identifier (C++) (see page 306)	The first non-whitespace character after a `#define` must be an identifier. The compiler found some other character.
E2155: Too many default cases (C++) (see page 306)	The compiler encountered more than one default statement in a single switch.
E2156: Default outside of switch (C++) (see page 306)	The compiler encountered a default statement outside a switch statement. This is most commonly caused by mismatched braces.
E2158: Operand of 'delete' must be non-const pointer (C++) (see page 306)	It is illegal to delete a variable that is not a pointer. It is also illegal to delete a pointer to a constant. For example:
E2159: Trying to derive a far class from the huge base 'base' (C++) (see page 306)	This error is no longer generated by the compiler.
E2160: Trying to derive a far class from the near base 'base' (C++) (see page 306)	If a class is declared (or defaults to) near, all derived classes must also be near.
E2161: Trying to derive a huge class from the far base 'base' (C++) (see page 307)	This error is no longer generated by the compiler.
E2162: Trying to derive a huge class from the near base 'base' (C++) (see page 307)	This error is no longer generated by the compiler.
E2163: Trying to derive a near class from the far base 'base' (C++) (see page 307)	If a class is declared (or defaults to) far, all derived classes must also be far.
E2164: Trying to derive a near class from the huge base 'base' (C++) (see page 307)	This error is no longer generated by the compiler.
E2165: Destructor cannot have a return type specification (C++) (see page 307)	C++ destructors never return a value, and you can't declare a return type or return a value.
E2166: Destructor for 'class' is not accessible (C++) (see page 307)	The destructor for this C++ class is protected or private, and can't be accessed here to destroy the class. If a class destructor is private, the class can't be destroyed, and thus can never be used. This is probably an error. A protected destructor can be accessed only from derived classes. This is a useful way to ensure that no instance of a base class is ever created, but only classes derived from it.
E2167: 'function' was previously declared with the language 'language' (C++) (see page 307)	Only one language modifier (cdecl pascal) can be given for a function. This function has been declared with different language modifiers in two locations.
E2168: Division by zero (C++) (see page 308)	Your source file contains a divide or remainder in a constant expression with a zero divisor.
E2169: 'identifier' specifies multiple or duplicate access (C++) (see page 308)	A base class can be declared public or private, but not both. This access specifier can appear no more than once for a base class.
E2170: Base class 'class' is included more than once (C++) (see page 308)	A C++ class can be derived from any number of base classes, but can be directly derived from a given class only once.
E2171: Body has already been defined for function 'function' (C++) (see page 308)	A function with this name and type was previously supplied a function body. A function body can only be supplied once. One cause of this error is not declaring a default constructor which you implement. For example:
E2172: Duplicate case (C++) (see page 308)	Each case of a switch statement must have a unique constant expression value.
E2175: Too many storage classes in declaration (C++) (see page 308)	A declaration can never have more than one storage class, either Auto, Register, Static, or Extern.
E2176: Too many types in declaration (C++) (see page 309)	A declaration can never have more than one basic type. Examples of basic types are: • char • class • int • float • double • struct • union • enum • typedef name
E2179: virtual specified more than once (C++) (see page 309)	The C++ reserved word "virtual" can appear only once in one member function declaration.

E2007: Dispid only allowed in __automated sections (C++) (see page 309)	The definition of dispids is only permitted in __automated sections.
Divide error (C++) (see page 309)	You tried to divide an integer by zero, which is illegal.
E2182: Illegal parameter to __emit__ (C++) (see page 309)	There are some restrictions on inserting literal values directly into your code with the __emit__ function. For example, you cannot give a local variable as a parameter to __emit__.
E2183: File must contain at least one external declaration (C++) (see page 309)	This compilation unit was logically empty, containing no external declarations. ANSI C and C++ require that something be declared in the compilation unit.
E2184: Enum syntax error (C++) (see page 310)	An `enum` declaration did not contain a properly formed list of identifiers.
E2185: The value for 'identifier' is not within the range of 'type-name' (C++) (see page 310)	You have attempted to assign a value that is out of the range of the specified type.
E2186: Unexpected end of file in comment started on line 'number' (C++) (see page 310)	The source file ended in the middle of a comment. This is normally caused by a missing close of comment (*/).
E2187: Unexpected end of file in conditional started on line 'number' (C++) (see page 310)	The source file ended before the compiler (or MAKE) encountered `#endif`. The `#endif` either was missing or misspelled. Every `#if` statement needs a matching `#endif` statement.
E2188: Expression syntax (C++) (see page 310)	This is a catch-all error message when the compiler parses an expression and encounters a serious error. *Possible Causes* This is most commonly caused by one of the following: • two consecutive operators • mismatched or missing parentheses • a missing semicolon on the previous statement. *Solutions* If the line where the error occurred looks syntactically correct, look at the line directly above for errors. Try moving the line with the error to a different location in the file and recompiling. If the error still occurs at the moved statement, the syntax error is occurring somewhere in that statement. If the error occurred... more (see page 310)
E2190: Unexpected closing brace (C++) (see page 311)	An extra right brace was encountered where none was expected. Check for a missing closing brace. *Useful Tip:* The IDE has a mechanism for finding a matching curly brace. If you put the cursor on the '{' or '}' character, hold down Ctrl, hit 'Q' and then '{' or '}', it will position the cursor on the matching brace.
E2189: extern variable cannot be initialized (C++) (see page 311)	The storage class extern applied to a variable means that the variable is being declared but not defined here--no storage is being allocated for it. Therefore, you can't initialize the variable as part of the declaration.
E2344: Earlier declaration of 'identifier' (C++) (see page 311)	This error message only shows up after the messages "Multiple declaration for 'identifier'" and "Type mismatch in redeclaration of 'identifier'". It tells you where the previous definition of the identifier in question was found by the compiler, so you don't have to search for it.
E2192: Too few parameters in call (C++) (see page 311)	This error message occurs when a call to a function with a prototype (via a function pointer) had too few arguments. Prototypes require that all parameters be given. Make certain that your call to a function has the same parameters as the function prototype.
E2193: Too few parameters in call to 'function' (C++) (see page 311)	A call to the named function (declared using a prototype) has too few arguments. Make certain that the parameters in the call to the function match the parameters of the function prototype.
E2194: Could not find file 'filename' (C++) (see page 311)	The compiler is unable to find the file supplied on the command line.
E2197: File name too long (C++) (see page 311)	The file name given in an `#include` directive was too long for the compiler to process. File names in DOS must be no more than 79 characters long.

E2195: Cannot evaluate function call (C++) (see page 312)	The error message is issued if someone tries to explicitly construct an object or call a virtual function. In integrated debugger expression evaluation, calls to certain functions (including implicit conversion functions, constructors, destructors, overloaded operators, and inline functions) are not supported.
E2198: Not a valid expression format type (C++) (see page 312)	Invalid format specifier following expression in the debug evaluate or watch window. A valid format specifier is an optional repeat value followed by a format character (c, d, f[n], h, x, m, p, r, or s).
E2200: Functions may not be part of a struct or union (C++) (see page 312)	This C struct or union field was declared to be of type function rather than pointer to function. Functions as fields are allowed only in C++.
Floating point error: Divide by 0 OR Floating point error: Domain OR Floating point error: Overflow (C++) (see page 312)	These fatal errors result from a floating-point operation for which the result is not finite: • Divide by 0 means the result is +INF or -INF exactly, such as 1.0/0.0. • Domain means the result is NAN (not a number), like 0.0/0.0. • Overflow means the result is +INF (infinity) or -INF with complete loss of precision, such as assigning 1e200*1e200 to a double.
Floating point error: Stack fault (C++) (see page 312)	The floating-point stack has been overrun. This error may be due to assembly code using too many registers or due to a misdeclaration of a floating-point function. The program prints the error message and calls abort and _exit. These floating-point errors can be avoided by masking the exception so that it doesn't occur, or by catching the exception with signal.
Floating point error: Partial loss of precision OR Floating point error: Underflow (C++) (see page 312)	These exceptions are masked by default, because underflows are converted to zero and losses of precision are ignored.
E2201: Too much global data defined in file (C++) (see page 313)	The sum of the global data declarations exceeds 64K bytes. This includes any data stored in the DGROUP (all global variables, literal strings, and static locals). *Solutions* Check the declarations for any array that might be too large. You can also remove variables from the DGROUP. Here's how: • Declare the variables as automatic. This uses stack space. • Dynamically allocate memory from the heap using calloc, malloc, or farmalloc for the variables. This requires the use of pointers. Literal strings are also put in the DGROUP. Get the file farstr.zip from our BBS to extract literal strings into their own segment.... more (see page 313)
E2203: Goto bypasses initialization of a local variable (C++) (see page 313)	In C++, it is illegal to bypass the initialization of a local variable. This error indicates a goto statement that can transfer control past this local variable.
E2204: Group overflowed maximum size: 'name' (C++) (see page 313)	The total size of the segments in a group (for example, DGROUP) exceeded 64K.
E2206: Illegal character 'character' (0x'value') (C++) (see page 313)	The compiler encountered some invalid character in the input file. The hexadecimal value of the offending character is printed. This can also be caused by extra parameters passed to a function macro.
E2207: Implicit conversion of 'type1' to 'type2' not allowed (C++) (see page 313)	When a member function of a class is called using a pointer to a derived class, the pointer value must be implicitly converted to point to the appropriate base class. In this case, such an implicit conversion is illegal.
E2208: Cannot access an inactive scope (C++) (see page 313)	You have tried to evaluate or inspect a variable local to a function that is currently not active. (This is an integrated debugger expression evaluation message.)

E2209: Unable to open include file 'filename' (C++) (see page 314)	The compiler could not find the named file. *Possible Causes* • The named file does not exist. • An `#include` file included itself. • You do not have FILES set in CONFIG.SYS on your root directory. *Solutions* • Verify that the named file exists. • Set FILES = 20 in CONFIG.SYS.
E2210: Reference member 'member' is not initialized (C++) (see page 314)	References must always be initialized, in the constructor for the class. A class member of reference type must have an initializer provided in all constructors for that class. This means you can't depend on the compiler to generate constructors for such a class, because it has no way of knowing how to initialize the references.
E2212: Function defined inline after use as extern (C++) (see page 314)	Functions can't become inline after they have already been used. Either move the inline definition forward in the file or delete it entirely. The compiler encountered something like:
E2211: Inline assembly not allowed in inline and template functions (C++) (see page 314)	The compiler can't handle inline assembly statements in a C++ inline or template function. You could eliminate the inline assembly code or, in the case of an inline function, make this a macro, and remove the inline storage class.
F1001: Internal code generator error (C++) (see page 315)	An error has occurred in the internal logic of the code generator. Contact CodeGear technical support.
E2413: Invalid template declaration (C++) (see page 315)	After the declarator of a template member, either a semicolon, an initialization, or a body was expected, but some other, illegal token was found. This message appears when a template member is declared outside of the template, but the syntax was wrong.
E2070: Invalid use of namespace 'identifier' (C++) (see page 315)	A namespace identifier was used in an illegal way, for example, in an expression.
E2214: Cannot have a 'non-inline function/static data' in a local class (C++) (see page 315)	All members of classes declared local to a function must be entirely defined in the class definition. This means that local classes cannot contain any static data members, and all of their member functions must have bodies defined within the class definition.
E2215: Linkage specification not allowed (C++) (see page 315)	Linkage specifications such as extern "C" are only allowed at the file level. Move this function declaration out to the file level.
E2216: Unable to create turboc.$ln (C++) (see page 315)	The compiler cannot create the temporary file TURBOC.$LN because it cannot access the disk or the disk is full.
E2218: Templates can only be declared at namespace or class scope (C++) (see page 315)	Templates cannot be declared inside classes or functions. They are only allowed in the global scope, or file level. For example:
E2217: Local data exceeds segment size limit (C++) (see page 316)	The local variables in the current function take up more than 64K.
E2219: Wrong number of arguments in call of macro 'macro' (C++) (see page 316)	Your source file called the named macro with an incorrect number of arguments.
E2220: Invalid macro argument separator (C++) (see page 316)	In a macro definition, arguments must be separated by commas. The compiler encountered some other character after an argument name. This is correct:
E2221: Macro argument syntax error (C++) (see page 316)	An argument in a macro definition must be an identifier. The compiler encountered some non-identifier character where an argument was expected.
E2222: Macro expansion too long (C++) (see page 316)	A macro can't expand to more than 4,096 characters.
E2223: Too many decimal points (C++) (see page 316)	The compiler encountered a floating-point constant with more than one decimal point.
E2224: Too many exponents (C++) (see page 316)	The compiler encountered more than one exponent in a floating-point constant.
E2225: Too many initializers (C++) (see page 316)	The compiler encountered more initializers than were allowed by the declaration being initialized.
E2226: Extra parameter in call (C++) (see page 317)	A call to a function, via a pointer defined with a prototype, had too many arguments.
E2227: Extra parameter in call to function (C++) (see page 317)	A call to the named function (which was defined with a prototype) had too many arguments given in the call.
E2228: Too many error or warning messages (C++) (see page 317)	There were more errors or warnings than allowed.

E2233: Cannot initialize a class member here (C++) (see page 317)	Individual members of structs, unions, and C++ classes can't have initializers. A struct or union can be initialized as a whole using initializers inside braces. A C++ class can only be initialized by the use of a constructor.
E2232: Constant/Reference member 'member' in class without constructors (C++) (see page 317)	A class that contains constant or reference members (or both) must have at least one user-defined constructor. Otherwise, there would be no way to ever initialize such members.
E2229: Member 'member' has the same name as its class (C++) (see page 317)	A static data member, enumerator, member of an anonymous union, or nested type cannot have the same name as its class. Only a member function or a non-static member can have a name that is identical to its class.
E2234: Memory reference expected (C++) (see page 317)	The built-in assembler requires a memory reference. You probably forgot to put square brackets around an index register operand.
E2231: Member 'member' cannot be used without an object (C++) (see page 318)	This means that you have written class::member where 'member' is an ordinary (non-static) member, and there is no class to associate with that member. For example, it is legal to write this:
E2235: Member function must be called or its address taken (C++) (see page 318)	A reference to a member function must be called, or its address must be taken with & operator. In this case, a member function has been used in an illegal context. For example:
O2237: DPMI programs must use the large memory model (C++) (see page 318)	The compiler no longer issues this error.
E2238: Multiple declaration for 'identifier' (C++) (see page 318)	This identifier was improperly declared more than once. This might be caused by conflicting declarations such as: • int a; double a; • a function declared two different ways, or • a label repeated in the same function, or • some declaration repeated other than an extern function or a simple variable This can also happen by inadvertently including the same header file twice. For example, given:
E2239: 'identifier' must be a member function (C++) (see page 319)	Most C++ operator functions can be members of classes or ordinary non-member functions, but these are required to be members of classes: • operator = • operator -> • operator ( ) • type conversions This operator function is not a member function but should be.
E2240: Conversion of near pointer not allowed (C++) (see page 319)	A near pointer cannot be converted to a far pointer in the expression evaluation box when a program is not currently running. This is because the conversion needs the current value of DS in the user program, which doesn't exist.
E2243: Array allocated using 'new' may not have an initializer (C++) (see page 319)	When initializing a vector (array) of classes, you must use the constructor that has no arguments. This is called the default constructor, which means that you can't supply constructor arguments when initializing such a vector.
E2244: 'new' and 'delete' not supported (C++) (see page 319)	The integrated debugger does not support the evaluation of the new and delete operators.
E2245: Cannot allocate a reference (C++) (see page 319)	You have attempted to create a reference using the new operator. This is illegal, because references are not objects and can't be created through new.
E2309: Inline assembly not allowed (C++) (see page 320)	Your source file contains inline assembly language statements and you are compiling it from within the integrated environment. You must use the BCC command to compile this source file from the DOS command line.
E2250: No base class to initialize (C++) (see page 320)	This C++ class constructor is trying to implicitly call a base class constructor, but this class was declared with no base classes. Check your declarations.

E2254: : expected after private/protected/private (C++) (see page 320)	When used to begin a private, protected, or public section of a C++ class, the reserved words "private," "protected," and "public" must be followed by a colon.
E2255: Use :: to take the address of a member function (C++) (see page 320)	If f is a member function of class c, you take its address with the syntax
E2256: No : following the ? (C++) (see page 320)	The question mark (?) and colon (:) operators do not match in this expression. The colon might have been omitted, or parentheses might be improperly nested or missing.
E2257: , expected (C++) (see page 320)	A comma was expected in a list of declarations, initializations, or parameters. This problem is often caused by a missing syntax element earlier in the file or one of its included headers.
E2258: Declaration was expected (C++) (see page 320)	A declaration was expected here but not found. This is usually caused by a missing delimiter such as a comma, semicolon, right parenthesis, or right brace.
E2259: Default value missing (C++) (see page 321)	When a C++ function declares a parameter with a default value, all of the following parameters must also have default values. In this declaration, a parameter with a default value was followed by a parameter without a default value.
E2260: Default value missing following parameter 'parameter' (C++) (see page 321)	All parameters following the first parameter with a default value must also have defaults specified.
E2263: Exception handling not enabled (C++) (see page 321)	A 'try' block was found with the exception handling disabled.
E2264: Expression expected (C++) (see page 321)	An expression was expected here, but the current symbol can't begin an expression. This message might occur where the controlling expression of an if or while clause is expected or where a variable is being initialized. This message is often due to a symbol that is missing or has been added.
E2266: No file names given (C++) (see page 321)	The command line contained no file names. You must specify a source file name.
E2265: No file name ending (C++) (see page 321)	The file name in an `#include` statement was missing the correct closing quote or angle bracket.
E2271: Goto statement missing label (C++) (see page 321)	The `goto` keyword must be followed by an identifier.
E2272: Identifier expected (C++) (see page 321)	An identifier was expected here, but not found. In C, an identifier is expected in the following situations: • in a list of parameters in an old-style function header • after the reserved words struct or union when the braces are not present, and • as the name of a member in a structure or union (except for bit fields of width 0). In C++, an identifier is also expected in these situations: • in a list of base classes from which another class is derived, following a double colon (::), and • after the reserved word "operator" when no operator symbol is present.
E2275: Opening brace expected (C++) (see page 322)	A left brace was expected at the start of a block or initialization.
E2276: (expected (C++) (see page 322)	A left parenthesis was expected before a parameter list.
E2274: < expected (C++) (see page 322)	The keyword `template` was not followed by <. Every template declaration must include the template formal parameters enclosed within < >, immediately following the template keyword.
E2277: Lvalue required (C++) (see page 322)	The left side of an assignment operator must be an addressable expression. Addressable expressions include the following: • numeric or pointer variables • structure field references or indirection through a pointer • a subscripted array element
E2278: Multiple base classes not supported for Delphi classes (C++) (see page 322)	Delphi style classes cannot have multiple base classes.
E2280: Member identifier expected (C++) (see page 322)	The name of a structure or C++ class member was expected here, but not found. The right side of a dot (.) or arrow (->) operator must be the name of a member in the structure or class on the left of the operator.

E2279: Cannot find default constructor to initialize member 'identifier' (C++) (see page 323)	When the following occurs 1.A C++ class 'class1' contains a member of class 'class2,' and 2.You want to construct an object of type 'class1' (but not from another object of type 'class1'). There must be a constructor class2::class2() so that the member can be constructed. This constructor without parameters is called the default constructor. The compiler will supply a default constructor automatically unless you have defined any constructor for class 'class2'. In that case, the compiler will not supply the default constructor automatically (you must supply one.
E2310: Only member functions may be 'const' or 'volatile' (C++) (see page 323)	Something other than a class member function has been declared `const` or `volatile`.
E2311: Non-virtual function 'function' declared pure (C++) (see page 323)	Only virtual functions can be declared pure, because derived classes must be able to override them.
E2283: Use . or -> to call 'function' (C++) (see page 323)	You attempted to call a member function without providing an object. This is required to call a member function.
E2284: Use . or -> to call 'member', or & to take its address (C++) (see page 323)	A reference to a non-static class member without an object was encountered. Such a member can't be used without an object, or its address must be taken with the & operator.
E2285: Could not find a match for 'argument(s)' (C++) (see page 323)	No C++ function could be found with parameters matching the supplied arguments. Check parameters passed to function or overload function for parameters that are being passed.
E2286: Overloaded function resolution not supported (C++) (see page 324)	In integrated debugger expression evaluation, resolution of overloaded functions or operators is not supported, not even to take an address.
E2287: Parameter 'number' missing name (C++) (see page 324)	In a function definition header, this parameter consisted only of a type specifier 'number' with no parameter name. This is not legal in C. (It is allowed in C++, but there's no way to refer to the parameter in the function.)
E2288: Pointer to structure required on left side of -> or ->* (C++) (see page 324)	Nothing but a pointer is allowed on the left side of the arrow (->) in C or C++. In C++ a -> operator is allowed.
E2290: 'code' missing] (C++) (see page 324)	This error is generated if any of the following occur: • Your source file declared an array in which the array bounds were not terminated by a right bracket. • The array specifier in an operator is missing a right bracket. • The operator [ ] was declared as operator [. • A right bracket is missing from a subscripting expression. Add the bracket or fix the declaration. Check for a missing or extra operator or mismatched parentheses.
E2291: brace expected (C++) (see page 324)	A right brace was expected at the end of a block or initialization.
E2292: Function should return a value (C++) (see page 324)	Your source file declared the current function to return some type other than `int` or `void`, but the compiler encountered a return with no value. This usually indicates some sort of error. Functions declared as returning `int` are exempt because older versions of C did not support `void` function return types.
E2293:) expected (C++) (see page 325)	A right parenthesis was expected at the end of a parameter list.
E2294: Structure required on left side of . or .* (C++) (see page 325)	The left side of a dot (.) operator (or C++ dot-star operator, .*) must evaluate to a structure type. In this case it did not. This error can occur when you create an instance of a class using empty parentheses, and then try to access a member of that 'object'.
E2312: 'constructor' is not an unambiguous base class of 'class' (C++) (see page 325)	A C++ class constructor is trying to call a base class constructor 'constructor.' This error can also occur if you try to change the access rights of 'class::constructor.' Check your declarations.
E2313: Constant expression required (C++) (see page 325)	Arrays must be declared with constant size. This error is commonly caused by misspelling a `#define` constant.
E2296: Templates not supported (C++) (see page 325)	An error has occurred while using the command-line utility H2ASH. See the online file "tsm_util.txt" for further information about this utility.

E2314: Call of nonfunction (C++) (see page 325)	The name being called is not declared as a function. This is commonly caused by incorrectly declaring the function or misspelling the function name.
E2321: Declaration does not specify a tag or an identifier (C++) (see page 325)	This declaration doesn't declare anything. This may be a struct or union without a tag or a variable in the declaration. C++ requires that something be declared. For example:
E2297: 'this' can only be used within a member function (C++) (see page 326)	In C++, "this" is a reserved word that can be used only within class member functions.
E2316: 'identifier' is not a member of 'struct' (C++) (see page 326)	You are trying to reference 'identifier' as a member of 'struct', but it is not a member. Check your declarations.
E2317: 'identifier' is not a parameter (C++) (see page 326)	In the parameter declaration section of an old-style function definition, 'identifier' is declared but not listed as a parameter. Either remove the declaration or add 'identifier' as a parameter.
E2319: 'identifier' is not a public base class of 'classtype' (C++) (see page 326)	The right operand of a .*, ->*, or ::operator was not a pointer to a member of a class that is either identical to (or an unambiguous accessible base class of) the left operand's class type.
E2320: Expression of scalar type expected (C++) (see page 326)	The !, ++, and -- operators require an expression of scalar type. Only these types are allowed: • char • short • int • long • enum • float • double • long double • pointer
E2302: No type information (C++) (see page 327)	The integrated debugger has no type information for this variable. Ensure that you've compiled the module with debug information. If it has, the module may have been compiled by another compiler or assembler.
E2303: Type name expected (C++) (see page 327)	One of these errors has occurred: • In declaring a file-level variable or a struct field, neither a type name nor a storage class was given. • In declaring a typedef, no type for the name was supplied. • In declaring a destructor for a C++ class, the destructor name was not a type name (it must be the same name as its class). • In supplying a C++ base class name, the name was not the name of a class.
E2304: 'Constant/Reference' variable 'variable' must be initialized (C++) (see page 327)	This C++ object is declared constant or as a reference, but is not initialized. It must be initialized at the point of declaration.
E2305: Cannot find 'class::class' ('class'&) to copy a vector OR Cannot find 'class'::operator=('class'&) to copy a vector (C++) (see page 327)	When a C++ class 'class1' contains a vector (array) of class 'class2', and you want to construct an object of type 'class1' from another object of type 'class 1', you must use this constructor:
E2306: Virtual base classes not supported for Delphi classes (C++) (see page 328)	Delphi style classes cannot be derived virtually, not even from other Delphi style classes.
E2308: do statement must have while (C++) (see page 328)	Your source file contained a do statement that was missing the closing while keyword.
E2322: Incorrect number format (C++) (see page 328)	The compiler encountered a decimal point in a hexadecimal number.
E2324: Numeric constant too large (C++) (see page 328)	String and character escape sequences larger than hexadecimal or octal 77 can't be generated. Two-byte character constants can be specified by using a second backslash. For example,

E2282: Namespace name expected (C++) (see page 328)	The name of a namespace symbol was expected.
E2334: Namespace member 'identifier' declared outside its namespace (C++) (see page 328)	Namespace members must be declared inside their namespace. You can only use explicit qualification to define a namespace member (for example, to give a body for a function declared in a namespace). The declaration itself must be inside the namespace.
E2325: Illegal octal digit (C++) (see page 329)	The compiler found an octal constant containing a non-octal digit (8 or 9).
E2329: Invalid combination of opcode and operands (C++) (see page 329)	The built-in assembler does not accept this combination of operands. *Possible causes* • There are too many or too few operands for this assembler opcode. • The number of operands is correct, but their types or order do not match the opcode.
E2327: Operators may not have default argument values (C++) (see page 329)	It is illegal for overloaded operators to have default argument values.
E2330: Operator must be declared as function (C++) (see page 329)	An overloaded operator was declared with something other than function type. For example:
E2333: Class member 'member' declared outside its class (C++) (see page 329)	C++ class member functions can be declared only inside the class declaration. Unlike nonmember functions, they can't be declared multiple times or at other locations.
E2335: Overloaded 'function name' ambiguous in this context (C++) (see page 329)	The only time an overloaded function name can be used or assigned without actually calling the function is when a variable or parameter of the correct function pointer type is initialized or assigned the address of the overload function. In this case, an overloaded function name has been used in some other context, for example, the following code will generate this error:
E2339: Cannot overload 'main' (C++) (see page 330)	You cannot overload main.
E2336: Pointer to overloaded function 'function' doesn't match 'type' (C++) (see page 330)	A variable or parameter is assigned (or initialized with) the address of an overloaded function. However, the type of the variable or parameter doesn't match any of the overloaded functions with the specified name.
E2337: Only one of a set of overloaded functions can be "C" (C++) (see page 330)	C++ functions are by default overloaded, and the compiler assigns a new name to each function. If you wish to override the compiler's assigning a new name by declaring the function `extern` "C", you can do this for only one of a set of functions with the same name. (Otherwise the linker would find more than one global function with the same name.)
E2338: Overlays only supported in medium, large, and huge memory models (C++) (see page 330)	The compiler no longer issues this error.
E2340: Type mismatch in parameter 'number' (C++) (see page 330)	The function called, via a function pointer, was declared with a prototype. However, the given parameter number (counting left to right from 1) could not be converted to the declared parameter type. When compiling C++ programs, this message is always preceded by another message that explains the exact reason for the type mismatch. That other message is usually "Cannot convert 'type1' to 'type2'" but the mismatch might be due to many other reasons.
E2341: Type mismatch in parameter 'number' in call to 'function' (C++) (see page 331)	Your source file declared the named function with a prototype, and the given parameter number (counting left to right from 1) could not be converted to the declared parameter type. When compiling C++ programs, this message is always preceded by another message that explains the exact reason for the type mismatch. That other message is usually "Cannot convert 'type1' to 'type2'", but the mismatch might be due to many other reasons.
E2342: Type mismatch in parameter 'parameter' (C++) (see page 331)	Your source file declared the function called via a function pointer with a prototype. However, the named parameter could not be converted to the declared parameter type. When compiling C++ programs, this message is always preceded by another message that explains the exact reason for the type mismatch. That other message is usually "Cannot convert 'type1' to 'type2'" but the mismatch might be due to many other reasons.

E2343: Type mismatch in parameter 'parameter' in call to 'function' (C++) (see page 331)	Your source file declared the named function with a prototype, and the named parameter could not be converted to the declared parameter type. When compiling C++ programs, this message is always preceded by another message that explains the exact reason for the type mismatch. That other message is usually "Cannot convert 'type1' to 'type2'" but the mismatch might be due to many other reasons.
E2345: Access can only be changed to public or protected (C++) (see page 331)	A C++ derived class can modify the access rights of a base class member, but only to public or protected. A base class member can't be made private.
E2349: Nonportable pointer conversion (C++) (see page 331)	An implicit conversion between a pointer and an integral type is required, but the types are not the same size. You must use an explicit cast. This conversion might not make any sense, so be sure this is what you want to do.
E2350: Cannot define a pointer or reference to a reference (C++) (see page 332)	It is illegal to have a pointer to a reference or a reference to a reference.
E2352: Cannot create instance of abstract class 'class' (C++) (see page 332)	Abstract classes (those with pure virtual functions) can't be used directly, only derived from. When you derive an abstract base class, with the intention to instantiate instances of this derived class, you must override each of the pure virtual functions of the base class exactly as they are declared. For example:
E2354: Two operands must evaluate to the same type (C++) (see page 332)	The types of the expressions on both sides of the colon in the conditional expression operator (?:) must be the same, except for the usual conversions. These are some examples of usual conversions • `char` to `int` • `float` to `double` • void* to a particular pointer In this expression, the two sides evaluate to different types that are not automatically converted. This might be an error or you might merely need to cast one side to the type of the other. When compiling C++ programs, this message is always preceded by another message that explains the exact reason for the type mismatch.... more (see page 332)
E2355: Recursive template function: 'x' instantiated 'y' (C++) (see page 333)	The compiler has detected a recursive template function instance. For example:
E2356: Type mismatch in redeclaration of 'identifier' (C++) (see page 333)	Your source file redeclared a variable with a different type than was originally declared for the variable. *Possible Causes* This can occur if a function is called and subsequently declared to return something other than an integer. *Solutions* If this has happened, you must declare the function before the first call to it.
E2357: Reference initialized with 'type1', needs lvalue of type 'type2' (C++) (see page 333)	A reference variable that is not declared constant must be initialized with an lvalue of the appropriate type. In this case, the initializer either wasn't an lvalue, or its type didn't match the reference being initialized.
E2358: Reference member 'member' needs a temporary for initialization (C++) (see page 333)	You provided an initial value for a reference type that was not an lvalue of the referenced type. This requires the compiler to create a temporary for the initialization. Because there is no obvious place to store this temporary, the initialization is illegal.

E2360: Invalid register combination (e.g. [BP+BX]) (C++) (see page 334)	The built-in assembler detected an illegal combination of registers in an instruction. These are valid index register combinations: • [BX] • [BP] • [SI] • [DI] • [BX+SI] • [BX+DI] • [BP+SI] • [BP+DI] Other index register combinations are not allowed.
E2361: 'specifier' has already been included (C++) (see page 334)	This type specifier occurs more than once in this declaration. Delete or change one of the occurrences.
E2362: Repeat count needs an lvalue (C++) (see page 334)	The expression before the comma (,) in the Watch or Evaluate window must be an accessible region of storage. For example, expressions like this one are not valid:
E2363: Attempting to return a reference to local variable 'identifier' (C++) (see page 334)	This C++ function returns a reference type, and you are trying to return a reference to a local (auto) variable. This is illegal, because the variable referred to disappears when the function exits. You can return a reference to any static or global variable, or you can change the function to return a value instead.
E2364: Attempting to return a reference to a local object (C++) (see page 334)	You attempted to return a reference to a temporary object in a function that returns a reference type. This may be the result of a constructor or a function call. This object will disappear when the function returns, making the reference illegal.
E2365: Member pointer required on right side of .* or ->* (C++) (see page 335)	The right side of a C++ dot-star (.*) or an arrow star (->*) operator must be declared as a pointer to a member of the class specified by the left side of the operator. In this case, the right side is not a member pointer.
E2366: Can't inherit non-RTTI class from RTTI base OR E2367 Can't inherit RTTI class from non-RTTI base (C++) (see page 335)	When virtual functions are present, the RTTI attribute of all base classes must match that of the derived class.
E2368: RTTI not available for expression evaluation (C++) (see page 335)	Expressions requiring RTTI are not supported by the expression evaluator in the integrated debugger. This error message is only issued by the expression evaluator (if you try to Inspect, Watch, or Evaluate), not by the compiler.
E2371: sizeof may not be applied to a bit field (C++) (see page 335)	sizeof returns the size of a data object in bytes, which does not apply to a bit field.
E2372: sizeof may not be applied to a function (C++) (see page 335)	sizeof can be applied only to data objects, not functions. You can request the size of a pointer to a function.
E2373: Bit field cannot be static (C++) (see page 335)	Only ordinary C++ class data members can be declared static, not bit fields.
E2374: Function 'function' cannot be static (C++) (see page 335)	Only ordinary member functions and the operators new and delete can be declared static. Constructors, destructors and other operators must not be static.
Stack overflow (C++) (see page 335)	This error is reported when you compile a function with the Test Stack Overflow option on, but there is not enough stack space to allocate the function's local variables. This error can also be caused by the following: • infinite recursion, or • an assembly language procedure that does not maintain the stack project • a large array in a function
E2376: statement missing (C++) (see page 336)	In a do, for, if, switch, or while statement, the compiler found no left parenthesis after the while keyword or test expression.
E2377: statement missing) (C++) (see page 336)	In a do, for, if, switch, or while statement, the compiler found no right parenthesis after the while keyword or test expression.
E2378: do-while or for statement missing ; (C++) (see page 336)	In a do or for statement, the compiler found no semicolon after the right parenthesis.

E2379: Statement missing ; (C++) (see page 336)	The compiler encountered an expression statement without a semicolon following it.
E2380: Unterminated string or character constant (C++) (see page 336)	The compiler found no terminating quote after the beginning of a string or character constant.
E2381: Structure size too large (C++) (see page 336)	Your source file declared a structure larger than 64K.
E2382: Side effects are not allowed (C++) (see page 336)	Side effects such as assignments, ++, or -- are not allowed in the debugger watch window. A common error is to use x = y (not allowed) instead of x == y to test the equality of x and y.
E2383: Switch selection expression must be of integral type (C++) (see page 336)	The selection expression in parentheses in a `switch` statement must evaluate to an integral type (`char, short, int, long, enum`). You might be able to use an explicit cast to satisfy this requirement.
E2433: Specialization after first use of template (C++) (see page 337)	An ANSI C++ rule requires that a specialization for a function template be declared before its first use. This error message is only issued when the ANSI conformance option (-A) is active.
E2384: Cannot call near class member function with a pointer of type 'type' (C++) (see page 337)	Also E2385 Cannot call near class member function 'function' with a pointer of type 'type' Member functions of near classes can't be called via a member pointer. This also applies to calls using pointers to members. (Remember, classes are near by default in the tiny, small, and medium memory models.) Either change the pointer to be near, or declare the class as far.
E2390: Type mismatch in parameter 'number' in template class name 'template' (C++) (see page 337)	The actual template argument value supplied for the given parameter did not exactly match the formal template parameter type. When compiling C++ programs, this message is always preceded by another message that explains the exact reason for the type mismatch. That other message is usually "Cannot convert 'type1' to 'type2'" but the mismatch might be due to many other reasons.
E2391: Type mismatch in parameter 'parameter' in template class name 'template' (C++) (see page 337)	The actual template argument value supplied for the given parameter did not exactly match the formal template parameter type. When compiling C++ programs, this message is always preceded by another message that explains the exact reason for the type mismatch. That other message is usually "Cannot convert 'type1' to 'type2'" but the mismatch might be due to many other reasons.
E2394: Too few arguments passed to template 'template' (C++) (see page 337)	A template class name was missing actual values for some of its formal parameters.
E2395: Too many arguments passed to template 'template' (C++) (see page 338)	A template class name specified too many actual values for its formal parameters.
E2396: Template argument must be a constant expression (C++) (see page 338)	A non-type template class argument must be a constant expression of the appropriate type. This includes constant integral expressions and addresses of objects or functions with external linkage or members.
E2401: Invalid template argument list (C++) (see page 338)	This error indicates that an illegal template argument list was found. In a template declaration, the keyword `template` must be followed by a list of formal arguments enclosed within < and > delimiters.
E2400: Nontype template argument must be of scalar type (C++) (see page 338)	A nontype formal template argument must have scalar type; it can have an integral, enumeration, or pointer type.
E2415: Template functions may only have 'type-arguments' (C++) (see page 338)	A function template was declared with a non-type argument. This is not allowed with a template function, as there is no way to specify the value when calling it.
E2425: 'member' is not a valid template type member (C++) (see page 338)	A member of a template with some actual arguments that depend on the formal arguments of an enclosing template was found not to be a member of the specified template in a particular instance.
E2428: Templates must be classes or functions (C++) (see page 338)	The declaration in a template declaration must specify either a class type or a function.
E2432: 'template' qualifier must name a template class or function instance' (C++) (see page 339)	When defining a template class member, the actual arguments in the template class name used as the left operand for the :: operator must match the formal arguments of the template class.
E2442: Two consecutive dots (C++) (see page 339)	Because an ellipsis contains three dots (...), and a decimal point or member selection operator uses one dot (.), two consecutive dots cannot legally occur in a C program.
E2443: Base class 'class' is initialized more than once (C++) (see page 339)	In a C++ class constructor, the list of initializations following the constructor header includes base class 'class' more than once.
E2444: Member 'member' is initialized more than once (C++) (see page 339)	In a C++ class constructor, the list of initializations following the constructor header includes the same member name more than once.

E2445: Variable 'identifier' is initialized more than once (C++) (see page 339)	This variable has more than one initialization. It is legal to declare a file level variable more than once, but it can have only one initialization (even if two are the same).
E2446: Function definition cannot be a typedef'ed declaration (C++) (see page 339)	In ANSI C, a function body cannot be defined using a typedef with a function Type. Redefine the function body.
E2132: Templates and overloaded operators cannot have C linkage (C++) (see page 339)	You tried to use a linkage specification with a template or overloaded operator. The most common cause for this error message is having the declaration wrapped in an extern "C" linkage specification.
E2447: 'identifier' must be a previously defined enumeration tag (C++) (see page 340)	This declaration is attempting to reference 'ident' as the tag of an enum type, but it has not been so declared. Correct the name, or rearrange the declarations.
E2448: Undefined label 'identifier' (C++) (see page 340)	The named label has a `goto` in the function, but no label definition.
E2449: Size of 'identifier' is unknown or zero (C++) (see page 340)	This identifier was used in a context where its size was needed. A struct tag might only be declared (the struct not defined yet), or an extern array might be declared without a size. It's illegal then to have some references to such an item (like sizeof) or to dereference a pointer to this type. Rearrange your declaration so that the size of 'identifier' is available.
E2450: Undefined structure 'structure' (C++) (see page 340)	The named structure was used in the source file, probably on a pointer to a structure, but had no definition in the source file. This is probably caused by a misspelled structure name or a missing declaration.
E2451: Undefined symbol 'identifier' (C++) (see page 340)	The named identifier has no declaration. *Possible Causes* • Actual declaration of identifier has been commented out. • Misspelling, either at this point or at the declaration. • An error in the declaration of the identifier. • The header file in which the identifier is declared was not included using `#include` Tools to help track down the problem: GREP (see page 170)
E2453: Size of the type 'identifier' is unknown or zero (C++) (see page 340)	This type was used in a context where its size was needed. For example, a struct tag might only be declared (the struct not defined yet). It's illegal then to have some references to such an item (like sizeof) or to dereference a pointer to this type. Rearrange your declarations so that the size of this type is available.
E2452: Size of the type is unknown or zero (C++) (see page 341)	This error message indicates that an array of unspecified dimension nested within another structure is initialized and the `-A` (ANSI) switch is on. For example:
E2454: union cannot be a base type (C++) (see page 341)	A union can't be used as a base type for another class type.
E2455: union cannot have a base type (C++) (see page 341)	In general, a C++ class can be of union type, but such a class can't be derived from any other class.
E2456: Union member 'member' is of type class with 'constructor' (or destructor, or operator =) (C++) (see page 341)	A union can't contain members that are of type class with user-defined constructors, destructors, or operator =.
E2461: '%s' requires run-time initialization/finalization (C++) (see page 341)	This message is issued when a global variable that is declared as __thread (a Win32-only feature) or a static data member of a template class is initialized with a non-constant initial value. This message is also issued when a global variable that is declared as __thread (a Win32-only feature) or a static data member of a template class has the type class with constructor or destructor.
E2464: 'virtual' can only be used with member functions (C++) (see page 341)	A data member has been declared with the `virtual` specifier. Only member functions can be declared virtual. For example:
E2465: unions cannot have virtual member functions (C++) (see page 342)	A union can't have virtual functions as its members.
E2466: void & is not a valid type (C++) (see page 342)	A reference always refers to an object, but an object cannot have the type void. Thus, the type void is not allowed.
E2467: 'Void function' cannot return a value (C++) (see page 342)	A function with a return type void contains a return statement that returns a value; for example, an int. Default = displayed

E2468: Value of type void is not allowed (C++) (see page 342)	A value of type `void` is really not a value at all, so it can't appear in any context where an actual value is required. Such contexts include the following: • the right side of an assignment • an argument of a function • the controlling expression of an if, for, or while statement.
E2469: Cannot use tiny or huge memory model with Windows (C++) (see page 342)	The compiler no longer issues this error.
E2006: CodeGuarded programs must use the large memory model and be targeted for Windows (C++) (see page 342)	The compiler no longer issues this error.
E2269: The function 'function' is not available (C++) (see page 342)	You tried to call a function that is known to the evaluator, but which was not present in the program being debugged, for example, an inline function.
E2124: Invalid function call (C++) (see page 343)	A requested function call failed because the function is not available in the program, a parameter cannot be evaluated, and so on. The evaluator issues this message.
E2213: Invalid 'expression' in scope override (C++) (see page 343)	The evaluator issues this message when there is an error in a scope override in an expression you are watching or inspecting. You can specify a symbol table, a compilation unit, a source file name, etc. as the scope of the expression, and the message will appear whenever the compiler cannot access the symbol table, compilation unit, or whatever.
E2236: Missing 'identifier' in scope override (C++) (see page 343)	The syntax of a scope override is somehow incomplete. The evaluator issues this message.
Pure virtual function called (C++) (see page 343)	This is a runtime error. It is generated if the body of a pure virtual function was never generated and somehow the compiler tried to call it.
E2095: String literal not allowed in this context (C++) (see page 343)	This error message is issued by the evaluator when a string literal appears in a context other than a function call.
Unexpected termination during compilation [Module Seg#:offset] OR Unexpected termination during linking [Module Seg#:offset] (C++) (see page 343)	If either of these errors occur, it indicates a catastrophic failure of the CodeGear tools. You should contact CodeGear to report the problem and to find a potential work around for your specific case. By isolating the test case as well as possible, you will increase the chance for either CodeGear or yourself to find a work around for the problem. Commonly, compiler failures can be worked around by moving the source code that is currently being compiled. Simple cases might be switching the order of variable declarations, or functions within the source module. Moving the scope and storage of... more (see page 343)
E2012: Cannot take address of 'main' (C++) (see page 344)	In C++, it is illegal to take the address of the main function.
E2016: Ambiguous override of virtual base member 'base_function': 'derived_function' (C++) (see page 344)	A virtual function in a virtual base class was overridden with two or more different functions along different paths in the inheritance hierarchy. For example,
E2021: Array must have at least one element (C++) (see page 344)	ANSI C and C++ require that an array be defined to have at least one element (objects of zero size are not allowed). An old programming trick declares an array element of a structure to have zero size, then allocates the space actually needed with malloc. You can still use this trick, but you must declare the array element to have (at least) one element if you are compiling in strict ANSI mode. Declarations (as opposed to definitions) of arrays of unknown size are still allowed. *Example*
E2023: Array of references is not allowed (C++) (see page 344)	It is illegal to have an array of references, because pointers to references are not allowed and array names are coerced into pointers.
E2032: Illegal use of closure pointer (C++) (see page 344)	A closure pointer variable is used incorrectly. Closure variables have limited usage. For instance, you can assign a function to a closure variable, and execute that function through the closure variable, but you cannot use a closure variable like a pointer variable.
E2040: Declaration terminated incorrectly (C++) (see page 345)	A declaration has an extra or incorrect termination symbol, such as a semicolon placed after a function body. A C++ member function declared in a class with a semicolon between the header and the opening left brace also generates this error.
E2047: Bad 'directive' directive syntax (C++) (see page 345)	A macro definition starts or ends with the ## operator, or contains the # operator that is not followed by a macro argument name. An example of this might be:
E2049: Class type 'type' cannot be marked as __declspec(delphireturn) (C++) (see page 345)	Classes marked as delphireturn are special classes that the compiler needs to recognize by name. These classes are predefined in the headers. Some of the delphireturn classes are Variant, AnsiString, and Currency. You cannot mark user-defined classes as delphireturn.

E2052: Dynamic function 'function' conflicts with base class 'class' (C++) (see page 345)	Some of the modifiers of this dynamic function conflict with the definition of the same function in the base class. The two functions should have the same modifiers. The following modifiers (among others) can cause conflicts: • __export • __import • declspec(naked) • declspec(package) • __fastcall
E2057: Exception specification not allowed here (C++) (see page 345)	Function pointer type declarations are not allowed to contain exception specifications.
E2058: Exception handling variable may not be used here (C++) (see page 346)	An attempt has been made to use one of the exception handling values that are restricted to particular exception handling constructs, such as GetExceptionCode().
E2065: Using namespace symbol 'symbol' conflicts with intrinsic of the same name (C++) (see page 346)	If you define a function in a namespace, which has a name that might be replaced by a call to an intrinsic when -Oi is on, it is not permitted to have a "using" declaration which refers to that member. For example, calls to "strcmp" are replaced by the intrinsic "__strcmp__" when -Oi is on. This means that the declaration "using N::strcmp;" would become "using N::__strcmp__", since the token replacement happens before the compiler's parser ever sees the tokens. An error displays in this case, because the compiler doesn't know how to process "N::__strcmp__".
E2067: 'main' must have a return type of int (C++) (see page 346)	In C++, function main has special requirements, one of which is that it cannot be declared with any return type other than int.
E2073: Nothing allowed after pragma option pop (C++) (see page 346)	The #pragma option pop can only be followed by comments, blanks, or end of line.
E2091: Functions cannot return arrays or functions (C++) (see page 346)	A function was defined to return an array or a function. Check to see if either the intended return was a pointer to an array or function (and perhaps the * is missing) or if the function definition contained a request for an incorrect datatype.
E2093: Operator 'operator' not implemented in type 'type' for arguments of the same type (C++) (see page 346)	The operator you are calling is not defined in this class. When you have an expression: x + x, where x is of type class X, the operator + has to be defined in class X and be accessible.
E2094: Operator 'operator' not implemented in type 'type' for arguments of type 'type' (C++) (see page 346)	The operator you are calling is not defined in this class. When you have an expression: x + x, where x is of type class X, the operator + has to be defined in class X and be accessible.
E2097: Explicit instantiation only allowed at file or namespace scope (C++) (see page 347)	The explicit instantiation operator "template" can only be used within global or namespace scope. It cannot be used to qualify a local class or a class member, for example.
E2098: Explicit specialization declarator "template<>" now required (C++) (see page 347)	When specializing a function, such as providing the definition for "foo<int>", so that foo behaves specially which called for the "int" argument, now requires that the declaration begin with an explicit specialization operator.
E2099: Explicit specialization only allowed at file or namespace scope (C++) (see page 347)	The explicit specialization operator template<> can only be used within global or namespace scope. It cannot be used to qualify a local class or a class member, for example.
E2101: 'export' keyword must precede a template declaration (C++) (see page 347)	The 'export' keyword can only occur before the keyword "template" ina template declaration. It cannot be used anywhere else.
E2103: Explicit instantiation must be used with a template class or function (C++) (see page 347)	The explicit instantiation operator "template" can only be used to refer to templates. It cannot be used with non-templates.
E2106: Explicit specialization must be used with a template class or function (C++) (see page 347)	The explicit specialization operator template<> can only be used in front of a template class or function. Using it with a normal class means nothing, and hence generates an error.
E2112: Unknown unit directive: 'directive' (C++) (see page 347)	You cannot use this name as a unit directive. Instead use one of the following unit directives: weak, smart_init, or deny.
E2118: Bit fields must have integral type (C++) (see page 348)	In C++, bit fields must have an integral type. This includes enumerations.
E2120: Cannot call 'main' from within the program (C++) (see page 348)	C++ does not allow recursive calls of main( ).
E2125: Compiler could not generate copy constructor for class 'class' OR Compiler could not generate default constructor for class 'class' OR Compiler could not generate operator = for class 'class' (C++) (see page 348)	Sometimes the compiler is required to generate a member function for the user. Whenever such a member function can't be generated due to applicable language rules, the compiler issues one of these error messages.
E2130: Circular property definition (C++) (see page 348)	Indicates that a property definition relies directly or indirectly on itself.
E2131: Objects of type 'type' cannot be initialized with { } (C++) (see page 348)	Ordinary C structures can be initialized with a set of values inside braces. C++ classes can only be initialized with constructors if the class has constructors, private members, functions, or base classes that are virtual.

E2148: Default argument value redeclared for parameter 'parameter' (C++) (see page 348)	When a parameter of a C++ function is declared to have a default value, this value can't be changed, redeclared, or omitted in any other declaration for the same function.
E2149: Default argument value redeclared (C++) (see page 349)	When a parameter of a C++ function is declared to have a default value, this value can't be changed, redeclared, or omitted in any other declaration for the same function.
E2151: Type mismatch in default value for parameter 'parameter' (C++) (see page 349)	The default parameter value given could not be converted to the type of the parameter. The message "Type mismatch in default argument value" is used when the parameter was not given a name. When compiling C++ programs, this message is always preceded by another message that explains the exact reason for the type mismatch. That other message is usually "Cannot convert 'type1' to 'type2'" but the mismatch might be due to many other reasons.
E2157: Deleting an object requires exactly one conversion to pointer operator (C++) (see page 349)	If a person uses the 'delete' operator on an object (note: not a pointer to an object, but an object itself), the standard requires that object to define exactly one "conversion to pointer operator" which will yield the pointer that gets freed. For example:
E2173: Duplicate handler for 'type1', already had 'type2' (C++) (see page 349)	It is not legal to specify two handlers for the same type.
E2174: The name handler must be last (C++) (see page 349)	In a list of catch handlers, if the specified handler is present, it must be the last handler in the list (that is, it cannot be followed by any more catch handlers).
E2177: Redeclaration of #pragma package with different arguments (C++) (see page 350)	You can have multiple #pragma package statements in a source file as long as they have the same arguments. This error occurs if the compiler encounters more than one #pragma package with different arguments in each.
E2178: VIRDEF name conflict for 'function' (C++) (see page 350)	The compiler must truncate mangled names to a certain length because of a name length limit that is imposed by the linker. This truncation may (in very rare cases) cause two names to mangle to the same linker name. If these names happen to both be VIRDEF names, the compiler issues this error message. The simplest workaround for this problem is to change the name of 'function' so that the conflict is avoided.
E2180: Dispid number already used by identifier (C++) (see page 350)	Dispids must be unique and the compiler checks for this.
E2181: Cannot override a 'dynamic/virtual' with a 'dynamic/virtual' function (C++) (see page 350)	When you declare a function dynamic, you cannot override this function in a derived class with a virtual function of the same name and type. Similarly when the function is declared virtual, you cannot override it with a dynamic one in a derived class.
E2202: Goto into an exception handler is not allowed (C++) (see page 350)	It is not legal to jump into a try block, or an exception handler that is attached to a try block.
E2205: Illegal type type in __automated section (C++) (see page 350)	Only certain types are allowed in __automated sections.
E2242: Specifier requires Delphi style class type (C++) (see page 351)	The stored, default, and nodefault storage specifiers are only allowed within property declarations of Delphi style class types.
E2247: 'member' is not accessible (C++) (see page 351)	You are trying to reference C++ class member 'member,' but it is private or protected and can't be referenced from this function. This sometimes happens when you attempt to call one accessible overloaded member function (or constructor), but the arguments match an inaccessible function. The check for overload resolution is always made before checking for accessibility. If this is the problem, try an explicit cast of one or more parameters to select the desired accessible function. Virtual base class constructors must be accessible within the scope of the most derived class. This is because C++ always constructs virtual base classes... more (see page 351)
E2248: Cannot find default constructor to initialize array element of type 'class' (C++) (see page 351)	When declaring an array of a class that has constructors, you must either explicitly initialize every element of the array, or the class must have a default constructor. The compiler will define a default constructor for a class unless you have defined any constructors for the class.
E2251: Cannot find default constructor to initialize base class 'class' (C++) (see page 352)	Whenever a C++ derived class 'class2' is constructed, each base class 'class1' must first be constructed. If the constructor for 'class2' does not specify a constructor for 'class1' (as part of 'class2's' header), there must be a constructor class1::class1() for the base class. This constructor without parameters is called the default constructor. The compiler will supply a default constructor automatically unless you have defined any constructor for class 'class1'. In that case, the compiler will not supply the default constructor automatically--you must supply one.
E2252: 'catch' expected (C++) (see page 352)	In a C++ program, a 'try' block must be followed by at least one 'catch' block.

E2253: Calling convention must be attributed to the function type, not the closure (C++) (see page 352)	The calling convention is in the wrong place in the closure declaration. For example,
E2261: Use of dispid with a property requires a getter or setter (C++) (see page 353)	This property needs either a getter or a setter.
E2262: '__except' or '__finally' expected following '__try' (C++) (see page 353)	In C, a '__try block' must be followed by a '__except' or '__finally' handler block.
E2270: > expected (C++) (see page 353)	A new-style cast (for example, dynamic_cast) was found with a missing closing ">".
E2273: 'main' cannot be declared as static or inline (C++) (see page 353)	You cannot make main static or inline. For example, you cannot use static int main() or inline int main().
E2281: Identifier1 requires definition of Identifier2 as a pointer type (C++) (see page 353)	To use Identifier1, there needs to be a definition for Identifier2, which is a type. Example where __classid is the first identifier and TClass, which can be found in clx.h, is the second one:
E2289: __published or __automated sections only supported for Delphi classes (C++) (see page 353)	The compiler needs to generate a special kind of vtable for classes containing __published and __automated sections. Therefore, these sections are only supported for Delphi style classes.
E2298: Cannot generate 'function' from template function 'template' (C++) (see page 354)	A call to a template function was found, but a matching template function cannot be generated from the function template.
E2301: Cannot use templates in closure arguments -- use a typedef (C++) (see page 354)	When declaring a closure type, the arguments passed to that closure must be of a simple type. Templates are not accepted. To pass a reference to an object of template type to a closure, you must declare a typedef, which counts as a simple type name.
E2307: Type 'type' is not a defined class with virtual functions (C++) (see page 354)	A dynamic_cast was used with a pointer to a class type that is either undefined, or doesn't have any virtual member functions.
E2315: 'Member' is not a member of 'class', because the type is not yet defined (C++) (see page 354)	The member is being referenced while the class has not been fully defined yet. This can happen if you forward declare class X, declare a pointer variable to X, and reference a member through that pointer; for example:
E2318: 'type' is not a polymorphic class type (C++) (see page 354)	This error is generated if the -RT compiler option (for runtime type information) is disabled and either dynamic_cast was used with a pointer to a class or you tried to delete a pointer to an object of a class that has a virtual destructor
E2323: Illegal number suffix (C++) (see page 355)	A numeric literal is followed by a suffix that is not recognized by the compiler.
E2326: Use __declspec(spec1[, spec2]) to combine multiple __declspecs (C++) (see page 355)	When you want to use several __declspec modifiers, the compiler will complain if you don't combine them into one __declspec. For example:
E2328: Classes with properties cannot be copied by value (C++) (see page 355)	This error occurs if you attempt to use the default assignment operator. For example, the following code generates this error given two labels on a form:
E2331: Number of allowable option contexts exceeded (C++) (see page 355)	You have interspersed too many source-code option changes (using #pragma option) between template declarations. For example:
E2332: Variable 'variable' has been optimized and is not available (C++) (see page 355)	You have tried to inspect, watch, or otherwise access a variable which the optimizer removed. This variable is never assigned a value and has no stack location.
E2476: Cannot overload 'function' (C++) (see page 356)	You cannot overload the specified function. This error is displayed if you tried to declare a function with the same name as another function, but the redeclaration is not legal. For example, if both functions have the 'extern "C"' linkage type, only one 'extern "C"' function can have a given name.
E2346: 'x' access specifier of property 'property' must be a member function (C++) (see page 356)	Only member functions or data members are allowed in access specifications of properties.
E2347: Parameter mismatch in access specifier 'specifier' of property 'property' (C++) (see page 356)	The parameters of the member function used to access a property don't match the expected parameters.
E2348: Storage specifier not allowed for array properties (C++) (see page 356)	Array properties cannot have a storage specification.
E2351: Static data members not allowed in __published or __automated sections (C++) (see page 357)	Only nonstatic data members and member functions are allowed in __published or __automated sections.
E2353: Class 'classname' is abstract because of 'member = 0' (C++) (see page 357)	This message is issued immediately after the "Cannot create instance of abstract class 'classname' error message and is intended to make it easier to figure out why a particular class is considered abstract by the compiler. For example, consider the following example of an illegal attempt to instantiate an abstract class:
E2359: Reference member 'member' initialized with a non-reference parameter (C++) (see page 357)	An attempt has been made to bind a reference member to a constructor parameter. Since the parameter will cease to exist the moment the constructor returns to its caller, this will not work correctly.
E2369: Cannot use the result of a property assignment as an rvalue' (C++) (see page 358)	The result of a property assignment is an lvalue. This implies for instance that chained assignments of properties is not allowed; for example, x = y = 5, where both x and y are properties. Certain embedded assignments of properties can also produce errors; for example, x != (y = z), where y is a property.

E2370: Simple type name expected (C++) (see page 358)	To ensure interoperability between Delphi and C++, there are restrictions on the type names mentioned in the parameter lists of published closure types. The parameter types have to be simple type names with optional const modifier and pointer or reference notation. So when declaring a closure type, the arguments passed to that closure must be of a simple type. For example, templates are not accepted. To pass a reference to an object of template type to a closure, you must declare a typedef, which counts as a simple type name.
E2398: Template function argument 'argument' not used in argument types (C++) (see page 358)	The given argument was not used in the argument list of the function. The argument list of a template function must use all of the template formal arguments; otherwise, there is no way to generate a template function instance based on actual argument types.
E2419: Error while instantiating template 'template' (C++) (see page 358)	An error occurred during the instantiation of a particular template. This message always follows some other error message that indicates what actually went wrong. This message is displayed to help track down which template instantiation introduced the problem.
E2424: Template class nesting too deep: 'class' (C++) (see page 358)	The compiler imposes a certain limit on the level of template class nesting. This limit is usually only exceeded through a recursive template class dependency. When this nesting limit is exceeded, the compiler issues this error message for all of the nested template classes. This usually makes it easy to spot the recursion. This error message is always followed by the fatal error "Out of memory".
E2457: Delphi style classes must be caught by reference (C++) (see page 359)	You can only catch a Delphi style object by pointer.
E2458: Delphi classes have to be derived from Delphi classes (C++) (see page 359)	You cannot derive a Delphi style class from a non-Delphi style class.
E2459: Delphi style classes must be constructed using operator new (C++) (see page 359)	Delphi style classes cannot be statically defined. They have to be constructed on the heap.
E2460: Delphi style classes require exception handling to be enabled (C++) (see page 360)	If you are using Delphi style classes in your program, you cannot turn off exception handling (compiler option `-x-`) when compiling your source code.
E2463: 'base' is an indirect virtual base class of 'class' (C++) (see page 360)	You can't create a pointer to a C++ member of a virtual base class. You have attempted to create such a pointer (either directly, or through a cast) and access an inaccessible member of one of your base classes.
Null pointer assignment (C++) (see page 360)	When a small or medium memory model program exits, a check is made to determine if the contents of the first few bytes within the program's data segment have changed. These bytes would never be altered by a working program. If they have been changed, this message is displayed to inform you that (most likely) a value was stored to an uninitialized pointer. The program might appear to work properly in all other respects; however, this is a serious bug which should be attended to immediately. Failure to correct an uninitialized pointer can lead to unpredictable behavior (including locking the... more (see page 360)
E2268: Call to undefined function 'function' (C++) (see page 360)	Your source file declared the current function to return some type other than `void` in C++ (or `int` in C), but the compiler encountered a return with no value. All `int` functions are exempt in C because in old versions of C, there was no `void` type to indicate functions that return nothing.
E2375: Assembler stack overflow (C++) (see page 360)	The assembler ran out of memory during compilation. Review the portion of code flagged by the error message to ensure that it uses memory correctly.
Initializing enumeration with type (C++) (see page 360)	You're trying to initialize an enum variable to a different type. For example,
<name> is not a valid identifier (C++) (see page 361)	The identifier name is invalid. Ensure that the first character is a letter or an underscore (_). The characters that follow must be letters, digits, or underscores, and there can not be any spaces in the identifier.
Example for "Temporary used ..." error messages (C++) (see page 361)	In this example, function f requires a reference to an int, and c is a char:
Application is running (C++) (see page 361)	The application you tried to run is already running. For Windows, make sure the message loop of the program has properly terminated.
Printf/Scanf floating-point formats not linked (C++) (see page 361)	Floating-point formats contain formatting information that is used to manipulate floating-point numbers in certain runtime library functions, such as scanf() and atof(). Typically, you should avoid linking the floating-point formats (which take up about 1K) unless they are required by your application. However, you must explicitly link the floating-point formats for programs that manipulate fields in a limited and specific way. Refer to the following list of potential causes (listed from most common to least common) to determine how to resolve this error: • CAUSE: Floating point set to None. You set the floating-point option to None when it should... more (see page 361)

W8000: Ambiguous operators need parentheses (C++) (see page 362)	(Command-line option to display warning: -wamb) This warning is displayed whenever two shift, relational, or bitwise-Boolean operators are used together without parentheses. Also, an addition or subtraction operator that appears without parentheses with a shift operator will produce this warning.
W8060: Possibly incorrect assignment (C++) (see page 362)	(Command-line option to suppress warning: -w-pia) This warning is generated when the compiler encounters an assignment operator as the main operator of a conditional expression (part of an if, while, or do-while statement). This is usually a typographical error for the equality operator. If you want to suppress this warning, enclose the assignment in parentheses and compare the whole thing to zero explicitly. For example, this code
W8002: Restarting compile using assembly (C++) (see page 362)	(Command-line option to suppress warning: -w-asc) The compiler encountered an asm with no accompanying or `#pragma` inline statement. The compile restarts using assembly language capabilities. Default = On
W8003: Unknown assembler instruction (C++) (see page 362)	(Command-line option to suppress warning: -w-asm) The compiler encountered an inline assembly statement with a disallowed opcode or an unknown token. Check the spelling of the opcode or token. `Note:` You will get a separate error message from the assembler if you entered illegal assembler source code. This warning is off by default.
W8052: Base initialization without a class name is now obsolete (C++) (see page 362)	(Command-line option to suppress warning: -w-obi) Early versions of C++ provided for initialization of a base class by following the constructor header with just the base class constructor parameter list. It is now recommended to include the base class name. This makes the code much clearer, and is required when you have multiple base classes. *Old way*
E2117: Bit fields must be signed or unsigned int (C++) (see page 363)	(Command-line option to display warning: -wbbf) In ANSI C, bit fields may not be of type signed char or unsigned char. When you're not compiling in strict ANSI mode, the compiler allows these constructs, but flags them with this warning.
W8064: Call to function with no prototype (C++) (see page 363)	(Command-line option to suppress warning: -w-pro) This message is given if the "Prototypes required" warning is enabled and you call a function without first giving a prototype for that function.
W8065: Call to function 'function' with no prototype (C++) (see page 363)	This message is given if the "Prototypes required" warning is enabled and you call function 'function' without first giving a prototype for that function.
W8009: Constant is long (C++) (see page 363)	(Command-line option to display warning: -wcln) The compiler encountered one of the following: • a decimal constant greater than 32,767 or • an octal, hexadecimal, or decimal constant greater than 65,535 without a letter l or L following it The constant is treated as a long.
W8008: Condition is always true OR W8008 Condition is always false (C++) (see page 363)	(Command-line option to suppress warning: -w-ccc) Whenever the compiler encounters a constant comparison that (due to the nature of the value being compared) is always true or false, it issues this warning and evaluates the condition at compile time. For example:
W8012: Comparing signed and unsigned values (C++) (see page 364)	(Command-line option to suppress warning: -w-csu) Since the ranges of signed and unsigned types are different the result of an ordered comparison of an unsigned and a signed value might have an unexpected result.

W8010: Continuation character \ found in // comment (C++) (see page 364)	(Command-line option to suppress warning: -w-com) This warning message is issued when a C++ // comment is continued onto the next line with backslash line continuation. The intention is to warn about cases where lines containing source code unintentionally become part of a comment because that comment happened to end in a backslash. If you get this warning, check carefully whether you intend the line after the // comment to be part of the comment. If you don't, either remove the backslash or put some other character after it. If you do, it's probably better coding style to start the... more (see page 364)
W8080: 'identifier' is declared but never used (C++) (see page 364)	(Command-line option to display warning: -wuse) The specified identifier was never used. This message can occur in the case of either local or static variables. It occurs when the source file declares the named local or static variable as part of the block just ending, but the variable was never used. In the case of local variables, this warning occurs when the compiler encounters the closing brace of the compound statement or function. In the case of static variables, this warning occurs when the compiler encounters the end of the source file. For example:
W8014: Declaration ignored (C++) (see page 365)	(Command-line option to suppress warning: -w-dig) An error has occurred while using the command-line utility H2ASH. See the online file "tsm_util.txt" for further information about this utility. Default = On
W8068: Constant out of range in comparison (C++) (see page 365)	(Command-line option to suppress warning: -w-rng) Your source file includes a comparison involving a constant sub-expression that was outside the range allowed by the other sub-expression's type. For example, comparing an unsigned quantity to -1 makes no sense. To get an unsigned constant greater than 32,767 (in decimal), you should either • cast the constant to unsigned--for example, (unsigned) 65535, or • append a letter u or U to the constant--for example, 65535u. Whenever this message is issued, the compiler still generates code to do the comparison. If this code ends up always giving the same result (such as comparing a char... more (see page 365)
W8016: Array size for 'delete' ignored (C++) (see page 365)	(Command-line option to suppress warning: -w-dsz) The C++ IDE issues this warning when you've specified the array size when deleting an array. With the new C++ specification, you don't need to make this specification. The compiler ignores this construct. This warning lets older code compile.
W8082: Division by zero (C++) (see page 365)	(Command-line option to suppress warning: -w-zdi) A divide or remainder expression had a literal zero as a divisor.
W8018: Assigning 'type' to 'enumeration' (C++) (see page 365)	(Command-line option to suppress warning: -w-eas) Assigning an integer value to an enum type. This is an error in C++, but is reduced to a warning to give existing programs a chance to work.
W8006: Initializing 'identifier' with 'identifier' (C++) (see page 366)	(Command-line option to suppress warning: `-w-bei`) You're trying to initialize an `enum` variable to a different type. For example, the following initialization will result in this warning, because 2 is of type int, not type enum count:
W8001: Superfluous & with function (C++) (see page 366)	(Command-line option to display warning: -wamp) An address-of operator (&) is not needed with function name; any such operators are discarded.
W8020: 'identifier' is declared as both external and static (C++) (see page 366)	(Command-line option to suppress warning: -w-ext) This identifier appeared in a declaration that implicitly or explicitly marked it as global or external, and also in a static declaration. The identifier is taken as static. You should review all declarations for this identifier.

W8007: Hexadecimal value contains more than three digits (C++) (see page 366)	(Command-line option to suppress warning = -w-big) Under older versions of C, a hexadecimal escape sequence could contain no more than three digits. The ANSI standard allows any number of digits to appear as long as the value fits in a byte. This warning results when you have a long hexadecimal escape sequence with many leading zero digits (such as \x00045). Older versions of C would interpret such a string differently.
W8024: Base class 'class1' is also a base class of 'class2' (C++) (see page 366)	(Command-line option to suppress warning: -w-ibc) A class inherits from the same base class both directly and indirectly. It is best to avoid this non-portable construct in your program code.
W8022: 'function1' hides virtual function 'function2' (C++) (see page 367)	(Command-line option to suppress warning: -w-hid) A virtual function in a base class is usually overridden by a declaration in a derived class. In this case, a declaration with the same name but different argument types makes the virtual functions inaccessible to further derived classes.
W8023: Array variable 'identifier' is near (C++) (see page 367)	(Command-line option to suppress warning: -w-ias) When you use set the Far Data Threshold option, the compiler automatically makes any global variables that are larger than the threshold size be far. When the variable is an initialized array with an unspecified size, its total size is not known when the compiler must decide whether to make it near or far, so the compiler makes it near. The compiler issues this warning if the number of initializers given for the array causes the total variable size to exceed the data size threshold. If the fact that the compiler made the variable... more (see page 367)
W8061: Initialization is only partially bracketed (C++) (see page 367)	(Command-line option to display warning: `-wpin`) When structures are initialized, braces can be used to mark the initialization of each member of the structure. If a member itself is an array or structure, nested pairs of braces can be used. This ensures that the compiler's idea and your idea of what value goes with which member are the same. When some of the optional braces are omitted, the compiler issues this warning.
W8038: constant member 'identifier' is not initialized (C++) (see page 367)	(Command-line option to suppress warning: -w-nci) This C++ class contains a constant member 'member' that doesn't have an initialization. Note that constant members can be initialized only; they can't be assigned to.
W8071: Conversion may lose significant digits (C++) (see page 367)	(Command-line option to display warning: -wsig) For an assignment operator or some other circumstance, your source file requires a conversion from a larger integral data type to a smaller integral data type where the conversion exists. Because the integral data type variables don't have the same size, this kind of conversion might alter the behavior of a program.
W8043: Macro definition ignored (C++) (see page 368)	(Command-line option to suppress warning: -w-nma) An error has occurred while using the command-line utility H2ASH. See the online file "tsm_util.txt" for further information about this utility.
W8017: Redefinition of 'x' is not identical (C++) (see page 368)	(Command-line option to suppress warning: -w-dup) Your source file redefined the macro 'ident' using text that was not exactly the same as the first definition of the macro. The new text replaces the old.
W8079: Mixing pointers to different 'char' types (C++) (see page 368)	(Command-line option to display warning: -wucp) You converted a signed char pointer to an unsigned char pointer, or vice versa, without using an explicit cast. (Strictly speaking, this is incorrect, but it is often harmless.)
W8067: Both return and return with a value used (C++) (see page 368)	(Command-line option to suppress warning: -w-ret) The current function has return statements with and without values. This is legal C, but almost always generates an error. Possibly a return statement was omitted from the end of the function.
W8048: Use qualified name to access member type 'identifier' (C++) (see page 368)	(Command-line option to suppress warning: -w-nst) In previous versions of the C++ specification, `typedef` and tag names declared inside classes were directly visible in the global scope. In the latest specification of C++, these names must be prefixed with class`::`qualifier if they are to be used outside of their class scope. The compiler issues this warning whenever a name is uniquely defined in a single class. The compiler permits this usage without class`::`. This allows older versions of code to compile.

W8039: Constructor initializer list ignored (C++) (see page 368)	(Command-line option to suppress warning: -w-ncl) An error has occurred while using the command-line utility H2ASH. See the online file "tsm_util.txt" for further information about this utility.
W8040: Function body ignored (C++) (see page 369)	(Command-line option to suppress warning: -w-nfd) An error has occurred while using the command-line utility H2ASH. See the online file "tsm_util.txt" for further information about this utility.
W8042: Initializer for object 'x' ignored (C++) (see page 369)	(Command-line option to suppress warning: -w-nin) An error has occurred while using the command-line utility H2ASH. See the online file "tsm_util.txt" for further information about this utility.
W8044: #undef directive ignored (C++) (see page 369)	(Command-line option to suppress warning: -w-nmu) An error has occurred while using the command-line utility H2ASH. See the online file "tsm_util.txt" for further information about this utility.
W8037: Non-const function 'function' called for const object (C++) (see page 369)	(Command-line option to suppress warning = -w-ncf) A non-const member function was called for a const object. (This is an error, but was reduced to a warning to give existing programs a chance to work.)
W8051: Non-volatile function 'function' called for volatile object (C++) (see page 369)	(Command-line option to suppress warning: -w-nvf) In C++, a class member function was called for a volatile object of the class type, but the function was not declared with volatile following the function header. Only a volatile member function can be called for a volatile object. For example, if you have
W8019: Code has no effect (C++) (see page 370)	(Command-line option to suppress warning: -w-eff) This warning is issued when the compiler encounters a statement with some operators that have no effect. For example, the statement
W8057: Parameter 'parameter' is never used (C++) (see page 370)	(Command-line option to suppress warning: -w-par) The named parameter, declared in the function, was never used in the body of the function. This might or might not be an error and is often caused by misspelling the parameter. This warning can also occur if the identifier is redeclared as an automatic (local) variable in the body of the function. The parameter is masked by the automatic variable and remains unused.
W8070: Function should return a value (C++) (see page 370)	(Command-line option to suppress warning: `-w-rvl`) This function was declared (maybe implicitly) to return a value. The compiler found a return statement without a return value, or it reached the end of the function without finding a return statement. Either return a value or change the function declaration to return void.
W8047: Declaration of static function function ignored (C++) (see page 370)	(Command-line option to suppress warning: -w-nsf) An error has occurred while using the command-line utility H2ASH. See the online file "tsm_util.txt" for further information about this utility.
W8041: Negating unsigned value (C++) (see page 370)	(Command-line option to suppress warning: -w-ngu) Basically, it makes no sense to negate an unsigned value because the result will still be unsigned.
W8054: Style of function definition is now obsolete (C++) (see page 371)	(Command-line option to suppress warning = -w-ofp) In C++, this old C style of function definition is illegal:
W8025: Ill-formed pragma (C++) (see page 371)	(Command-line option to suppress warning: -w-ill) A pragma does not match one of the pragmas expected by the compiler.
W8063: Overloaded prefix operator 'operator' used as a postfix operator (C++) (see page 371)	(Command-line option to suppress warning: -w-pre) The C++ specification allows you to overload both the prefix and postfix versions of the ++ and -- operators. Whenever the prefix operator is overloaded, but is used in a postfix context, the compiler uses the prefix operator and issues this warning. This allows older code to compile.
W8015: Declare 'type' prior to use in prototype (C++) (see page 371)	(Command-line option to suppress warning: -w-dpu) When a function prototype refers to a structure type that has not previously been declared, the declaration inside the prototype is not the same as a declaration outside the prototype. For example,
W8069: Nonportable pointer conversion (C++) (see page 372)	(Command-line option to suppress warning: `-w-rpt`) A nonzero integral value is used in a context where a pointer is needed or where an integral value is needed; the sizes of the integral type and pointer are the same. Use an explicit cast if this is what you really meant to do.

W8066: Unreachable code (C++) (see page 372)	(Command-line option to suppress warning: -w-rch) A break, continue, goto, or return statement was not followed by a label or the end of a loop or function. The compiler checks while, do, and for loops with a constant test condition, and attempts to recognize loops that can't fall through.
W8029: Temporary used for parameter '???' (C++) (see page 372)	(Command-line option to suppress warning: -w-lvc) In C++, a variable or parameter of reference type must be assigned a reference to an object of the same type. If the types do not match, the actual value is assigned to a temporary of the correct type, and the address of the temporary is assigned to the reference variable or parameter. The warning means that the reference variable or parameter does not refer to what you expect, but to a temporary variable, otherwise unused. In the following example, function f requires a reference to an int, and c is a char:
W8031: Temporary used for parameter 'parameter' OR W8029 Temporary used for parameter 'number' OR W8030 Temporary used for parameter 'parameter' in call to 'function' OR W8032 Temporary used for parameter 'number' in call to 'function' (C++) (see page 372)	(Command-line option to suppress warning: -w-lvc) In C++, a variable or parameter of reference type must be assigned a reference to an object of the same type. If the types do not match, the actual value is assigned to a temporary of the correct type, and the address of the temporary is assigned to the reference variable or parameter. The warning means that the reference variable or parameter does not refer to what you expect, but to a temporary variable, otherwise unused.
W8032: Temporary used for parameter 2 in call to '???' (C++) (see page 373)	(Command-line option to suppress warning: -w-lvc) In C++, a variable or parameter of reference type must be assigned a reference to an object of the same type. If the types do not match, the actual value is assigned to a temporary of the correct type, and the address of the temporary is assigned to the reference variable or parameter. The warning means that the reference variable or parameter does not refer to what you expect, but to a temporary variable, otherwise unused. In the following example, function f requires a reference to an int, and c is a char:
W8028: Temporary used to initialize 'identifier' (C++) (see page 373)	(Command-line option to suppress warning: -w-lin) In C++, a variable or parameter of reference type must be assigned a reference to an object of the same type. If the types do not match, the actual value is assigned to a temporary of the correct type, and the address of the temporary is assigned to the reference variable or parameter. The warning means that the reference variable or parameter does not refer to what you expect, but to a temporary variable, otherwise unused. *Example* In this example, function f requires a reference to an int, and c is a char:
W8074: Structure passed by value (C++) (see page 373)	(Command-line option to display warning: -wstv) This warning is generated any time a structure is passed by value as an argument. It is a frequent programming mistake to leave an address-of operator (&) off a structure when passing it as an argument. Because structures can be passed by value, this omission is acceptable. This warning provides a way for the compiler to warn you of this mistake.
W8011: Nonportable pointer comparison (C++) (see page 374)	(Command-line option to suppress warning: -w-cpt) Your source file compared a pointer to a non-pointer other than the constant 0. You should use a cast to suppress this warning if the comparison is proper.
W8075: Suspicious pointer conversion (C++) (see page 374)	(Command-line option to suppress warning: -w-sus) The compiler encountered some conversion of a pointer that caused the pointer to point to a different type. You should use a cast to suppress this warning if the conversion is proper. A common cause of this warning is when the C compiler converts a function pointer of one type to another (the C++ compiler generates an error when asked to do that). It can be suppressed by doing a typecast. Here is a common occurrence of it for Windows programmers:
W8059: Structure packing size has changed (C++) (see page 374)	(Command-line option to suppress warning: -w-pck) This warning message is issued when the structure alignment is different after including a file than it was before including that file. The intention is to warn you about cases where an include file changes structure packing, but by mistake doesn't restore the original setting at the end. If this is intentional, you can give a #pragma nopackwarning directive at the end of an include file to disable the warning for this file. The warning can be disabled altogether by #pragma warn -pck.

W8045: No declaration for function 'function' (C++) (see page 374)	(Command-line option to display warning: -wnod) This message is given if you call a function without first declaring that function. In C, you can declare a function without presenting a prototype, as in
W8073: Undefined structure 'structure' (C++) (see page 375)	(Command-line option to display warning = `-wstu`) Your source file used the named structure on some line before where the error is indicated (probably on a pointer to a structure) but had no definition for the structure. This is probably caused by a misspelled structure name or a missing declaration.
W8013: Possible use of 'identifier' before definition (C++) (see page 375)	(Command-line option to display warning: -wdef) Your source file used the variable 'identifier' in an expression before it was assigned a value. The compiler uses a simple scan of the program to determine this condition. If the use of a variable occurs physically before any assignment, this warning will be generated. Of course, the actual flow of the program can assign the value before the program uses it.
W8004: 'identifier' is assigned a value that is never used (C++) (see page 375)	(Command-line option to suppress warning: -w-aus) The variable appears in an assignment, but is never used anywhere else in the function just ending. The warning is indicated only when the compiler encounters the closing brace. The `#pragma warn -aus` switch has function-level granularity. You cannot turn off this warning for individual variables within a function; it is either off or on for the whole function.
W8081: Void functions may not return a value (C++) (see page 375)	(Command-line option to suppress warning: -w-voi) Your source file declared the current function as returning void, but the compiler encountered a return statement with a value. The value of the return statement will be ignored.
W8078: Throw expression violates exception specification (C++) (see page 376)	(Command-line option to suppress warning: -w-thr) This warning happens when you add an exception specification to a function definition and you throw a type in your function body that is not mentioned in your exception specification. The following program would generate this warning:
W8021: Handler for 'type1' hidden by previous handler for 'type2' (C++) (see page 376)	(Command-line option to suppress warning: -w-hch) This warning is issued when a handler for a type 'D' that is derived from type 'B' is specified after a handler for B', since the handler for 'D' will never be invoked.
W8056: Integer arithmetic overflow (C++) (see page 376)	The compiler detected an overflow condition in an integer math expression. For example:
W8035: User-defined message (C++) (see page 376)	The error message for which you have requested Help is a user-defined warning. In C++ code, user-defined messages are introduced by using the `#pragma` message compiler syntax. `Note:` In addition to messages that you introduce with the `#pragma` message compiler syntax, user-defined warnings can be introduced by third party libraries. Should you require Help about a third party warning, please contact the vendor of the header file that issued the warning.
W8049: Use '> >' for nested templates Instead of '>>' (C++) (see page 376)	(Command-line option to suppress warning: -w-ntd) Whitespace is required to separate the closing ">" in a nested template name, but since it is an extremely common mistake to leave out the space, the compiler accepts a ">>" with this warning.
W8026: Functions with exception specifications are not expanded inline (C++) (see page 377)	*Also:Functions taking class by value arguments are not expanded inline* (Command-line option to suppress warning: -w-inl) Exception specifications are not expanded inline: Check your inline code for lines containing exception specification. Functions taking class-by-value argument(s) are not expanded inline: When exception handling is enabled, functions that take class arguments by value cannot be expanded inline. `Note:` Functions taking class parameters by reference are not subject to this restriction.

W8058: Cannot create pre-compiled header: 'reason' (C++) (see page 377)	(Command-line option to suppress warning: -w-pch) This warning is issued when pre-compiled headers are enabled but the compiler could not generate one, for one of the following reasons: *ReasonExplanation* write failedThe compiler could not write to the pre-compiled header file. This occurs if you specified an invalid location to cache precompiled headers or if the disk is full. code in headerOne of the headers contained a non-inline function body. initialized data in headerOne of the headers contained a global variable definition (in C, a global variable with an initializer; in C++ any variable not declared as 'extern'). header incompleteThe... more (see page 377)
W8046: Pragma option pop with no matching option push (C++) (see page 377)	The compiler encountered a #pragma option pop before a previous #pragma option push, or in the case of nesting, there are more occurrences of #pragma option pop than of #pragma option push.
W8050: No type OBJ file present; disabling external types option. (C++) (see page 377)	(Command-line option to suppress warning: -w-nto) A precompiled header file references a type object file, but the type object file cannot be found. This is not a fatal problem but will make your object files larger than necessary.
W8027: Functions containing 'statement' are not expanded inline (C++) (see page 378)	(Command-line option to suppress warning: -w-inl) *Where:* 'statement' can be any of the following: • Static variables • Aggregate initializers • Some return statements • Local destructors • Some if statements • Local classes • Missing return statements • Disallowed reserved words listed under "Reserved words" below. *Reserved words* Functions containing any of these reserved words can't be expanded inline, even when specified as inline:
W8036: Non-ANSI keyword used: 'keyword' (C++) (see page 378)	(Command-line option to display warning: -wnak) A non-ANSI keyword (such as '__fastcall') was used when strict ANSI conformance was requested via the -A option.
W8053: 'ident' is obsolete (C++) (see page 379)	(Command-line option to suppress warning: -w-obs) Issues a warning upon usage for any "C" linkage function that has been specified. This will warn about functions that are "obsolete". Here's an example of it's usage:
W8103: Path 'path' and filename 'filename' exceed maximum size of 'n' (C++) (see page 379)	(Command-line option to display warning: -wstv) In looking up include files, the C++ compiler has encountered a file whose path and filename contain more characters than are allowed in the Windows maximum. Rename the paths and filenames that you can, and shorten their names wherever possible.
W8062: Previous options and warnings not restored (C++) (see page 379)	The compiler didn't encounter a #pragma option pop after a previous #pragma option push, or in the case of nesting, there are more occurrences of #pragma option push than of #pragma option pop.
W8055: Possible overflow in shift operation (C++) (see page 379)	The compiler detects cases where the number of bits shifted over is larger than the number of bits in the affected variable; for example:
W8072: Suspicious pointer arithmetic (C++) (see page 379)	This message indicates an unintended side effect to the pointer arithmetic (or array indexing) found in an expression.

W8033: Conversion to 'type' will fail for members of virtual base 'class' (C++) (see page 380)	(Command-line option to suppress warning: -w-mpc) This warning is issued only if the `-Vv` option is in use. The warning may be issued when a member pointer to one type is cast to a member pointer of another type and the class of the converted member pointer has virtual bases. Encountering this warning means that at runtime, if the member pointer conversion cannot be completed, the result of the cast will be a NULL member pointer.
W8034: Maximum precision used for member pointer type 'type' (C++) (see page 380)	(Command-line option to suppress warning: -w-mpd) When a member pointer type is declared, its class has not been fully defined, and the `-Vmd` option has been used, the compiler has to use the most general (and the least efficient) representation for that member pointer type. This can cause less efficient code to be generated (and make the member pointer type unnecessarily large), and can also cause problems with separate compilation; see the `-Vm` compiler switch for details.
E2537: Cannot create instance of abstract class (C++) (see page 380)	This class is an abstract class, which you cannot instantiate.
E2018: Cannot catch 'identifier' -- ambiguous base class 'identifier' (C++) (see page 380)	It is not legal to catch a class that contains more than one copy of a (non-virtual) base class. However, you can catch the exception as a more derived type. For example:
E2550: No arguments can follow a variadic template in an argument list (C++) (see page 381)	In an argument list, the variadic template must not be followed by arguments.
E2538: Static assert failed: '%s' (C++) (see page 381)	See Static Assertions (see page 498) for details about how to use static_assert., which is one of the C++0x features.
E2548: ... was unexpected; expression is not a variadic template pattern (C++) (see page 381)	This message pertains to the expected syntax of variadic templates.
E2543: Combination of options 'options' is not permitted (C++) (see page 381)	Eliminate the combination of options. For example, you cannot combine the C++ compiler options -b- and -bi because -b- turns off all -b options, including -bi.
E2549: Operand is not a parameter pack (C++) (see page 381)	A parameter pack is required in the indicated location. This message pertains to variadic templates.
E2544: Function exception specifications do not match (C++) (see page 381)	The throw specifications on two function declaration/definitions which refer to the same function do not agree. Rewrite the function exception specifications to match.
E2536: Incomplete type cannot be part of a exception declaration (C++) (see page 381)	This error occurs when an incomplete type is used in exception declaration. From C++ ISO 14882:1998 15.3.1: "The exception-declaration shall not denote an incomplete type. The exception-declaration shall not denote a pointer or reference to an incomplete type, other than void*, const void*, volatile void*, or const volatile void*. Types shall not be defined in an exception-declaration.
E2535: Incomplete type cannot be part of a throw specification (C++) (see page 382)	This error occurs when an incomplete type is used in a throw specification. From C++ ISO 14882:1998 15.1.3: "The type of the throw-expression shall not be an incomplete type, or a pointer or reference to an incomplete type, other than void*, const void*, volatile void*, or const volatile void*." This includes exception specifications (15.4.1).
E2532: Constant in new expression requires an initializer (C++) (see page 382)	If the type is const then either an initializer must be present or the non-POD class must have a user-declared constructor. Error in ANSI mode, warning if ANSI mode is not set.
E2541: Attribute '%s' cannot be set (C++) (see page 382)	This error occurs if the specified attribute cannot be applied to this entity.
E2545: Enum underlying type must be an integral (C++) (see page 382)	Ensure that the underlying type of the enumeration is an integral type. The underlying type of a scoped enum is fixed to int unless explicitly provided by the user. The underlying type of a 'classic' enum remains unspecified unless fixed by the user. For more information, see Strongly Typed Enums (see page 498).
E2546: Redeclaration of enum is not identical (C++) (see page 382)	This error occurs if: • a re-declaration of an enum has a different underlying type • a scoped enum is re-declared as an unscoped enum • an unscoped enum is re-declared as a scoped enum For more information, see Strongly Typed Enums (see page 498).
E2533: Parameter mismatch (wanted typename) (C++) (see page 382)	This error occurs when a parameter passed to a type trait function is not the correct type.

E2534: Integral constant expression expected (C++) (see page 382)	Integral constant expressions are described in section 5.19 of the C++ standard, and are sometimes referred to as "compile time constants". A working draft for the C++ standard can be found at http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2008/n2588.pdf.
E2531: Parameter is an incomplete type (C++) (see page 383)	This error occurs when an incomplete type is passed into a type trait function that does not accept incomplete type parameters. For example:
E2539: Constant expression expected (C++) (see page 383)	You need to supply a constant expression in the indicated location. For details about using a constant expression in a static assertion, see Static Assertions (see page 498).
E2547: ... expected (C++) (see page 383)	An ellipsis (...) is expected in the location indicated.
E2540: String literal expected (C++) (see page 383)	You need to specify a string literal in the position indicated in the error message. A string literal is the second argument in a static assertion. For details about using a static assertion, see Static Assertions (see page 498).
E2552: This feature is not (yet) supported (C++) (see page 383)	Support might be added in a coming release.
E2542: '%s' is marked 'final' and cannot be overriden (C++) (see page 383)	The attribute 'final' applies to class definitions and to virtual member functions being declared in a class definition. If the attribute is specified for a class definition, it is equivalent to being specified for each virtual member function of that class, including inherited member functions. If a virtual member function f in some class B is marked 'final' and in a class D derived from B, a function D::f overrides B::f, the program is ill-formed.
E2553: %s mismatch in redeclaration of '%s' (C++) (see page 383)	Attributes specified on a declaration have to be a subset of attributes specified on a definition.
E2551: Return statement not allowed in __finally block (C++) (see page 384)	Rewrite the `__finally` block so that it does not contain a return statement. For more information, see Writing a finally Block in C++ (see page 2023) and finally keyword (see page 550).
W8104: Local Static with constructor dangerous for multi-threaded apps (C++) (see page 384)	(Command-line option to suppress warning: -w-mls) This warning is generated for local static objects with constructors for multithreaded programs. This situation can cause problems if two threads enter the containing function at the same time and no critical sections are present, allowing the constructor to potentially be called more than once.
W8106: %s are deprecated (C++) (see page 384)	You have used an old style syntax or language use that is deprecated -- that is, no longer recommended and might be phased out in the future.
W8110: Duplicate '%s' attribute directive ignored (C++) (see page 384)	(Command-line option to suppress warning: -w-dat) This warning is generated if the same attribute was specified more than once for the same entity.
W8108: Constant in new expression requires an initializer (C++) (see page 384)	(Command-line option to suppress warning: -w-nci) If the type is const then either an initializer must be present or the non-POD class must have a user-declared constructor. Error in ANSI mode, warning if ANSI mode is not set.
W8113: Inline function was declared with 'extern template' (C++) (see page 384)	(Command-line option to suppress warning: -w-iex) 'extern template' has no normative effect on inline functions. Implementations are encouraged to suppress out-of-line copies of inline functions that were declared with 'extern template'.
W8109: Parameter '%s' is a dependent type (C++) (see page 385)	(Command-line option to enable warning: -wpad) This warning is generated if a parameter of an intrinsic function is a dependent type and the dependency cannot be resolved.
W8105: Reference/Constant member 'identifier' in class without constructors (C++) (see page 385)	(Command-line option to suppress warning: -w-mnc) This warning is generated for a reference or constant member in a class without constructors if ANSI mode is not set. In ANSI mode this is an error.
W8107: Type name expected (C++) (see page 385)	(Command-line option to enable warning: -wntn) This warning is generated if the type of a class/union member is omitted in its declaration and ANSI mode is not set. Always an error in ANSI mode.
W8112: Unresolved dependencies in expression (C++) (see page 385)	(Command-line option to suppress warning: -w-dex) This warning is generated if dependencies in the expression cannot be resolved.

3.1.2.1 E2066: Invalid MOM inheritance (C++)

The compiler issues this error if the currently compiled class doesn't have the same MOM (Microsoft Object Model) related flags set as its direct parent.

This compiler error message is deprecated.

3.1.2.2 E2525: You must define _PCH_STATIC_CONST before including xstring to use this feature (C++)

You attempted to use a feature defined in xstring, part of the Dinkumware standard C++ library. The C++ compiler could not generate a precompiled header because there is a constant (defined in xstring) in the header. If you want to include xstring, you should first set the define _PCH_STATIC_CONST.

3.1.2.3 E2526: Property 'name' uses another property as getter/setter; Not allowed (C++)

Properties typically have both a getter and a setter, but a property cannot serve as either the getter or setter of another property.

3.1.2.4 E2008: Published property access functions must use __fastcall calling convention (C++)

The calling convention for access functions of a property (read, write, and stored) declared in a __published section must be __fastcall. This also applies to hoisted properties.

Example

```
struct__declspec(delphiclass) clxclass{int__fastcall Getter1(void); int__cdecl
Getter2(void); __published:int __property ip1 = {read = Getter1};    // OKint __property ip2 =
{read = Getter2};    // Error};
```

3.1.2.5 E2122: Function call terminated by unhandled exception 'value' at address 'addr' (C++)

This message is emitted when an expression you are evaluating while debugging includes a function call that terminates with an unhandled exception. For example, if in the debugger's evaluate dialog, you request an evaluation of the expression foo()+1 and the execution of the function foo() causes a GP fault, this evaluation produces the above error message.

You may also see this message in the watches window because it also displays the results of evaluating an expression.

3.1.2.6 E2506: Explicit specialization of 'specifier' is ambiguous: must specify template arguments (C++)

In the following code, explicit template arguments are necessary:

```
template<class T> void foo(T);
template<class T> void foo(T *);
template<> void foo(int *); // error, must say 'foo<int>' or 'foo<int *>'
```

3.1.2.7 E2483: Array dimension 'specifier' could not be determined (C++)

If, during instantiation of a type, an array dimension cannot be computed—usually this is due to some other error which would be reported—then this error will result.

For example, if an array dimension is dependent upon a template parameter but an error occurs while it is being parsed and the template argument being substituted does not yield a legal constant expression, this error is displayed.

3.1.2.8 E2509: Value out of range (C++)

The inline assembler has detected a numeric overflow in one of your expressions. Make sure all of your numbers can fit in 32 bits.

3.1.2.9 E2510: Operand size mismatch (C++)

Help is not available for this item.

3.1.2.10 E2050: __declspec(delphireturn) class 'class' must have exactly one data member (C++)

This is an internal compiler error. A class marked as a delphireturn class has more than one non-static data member.

3.1.2.11 E2530: Unrecognized option, or no help available (C++)

You have entered a command element that the C++ compiler cannot parse, or the option you entered has no associated help. Try again.

3.1.2.12 E2527: Option 'name' cannot be set via 'name' (C++)

An attempt was made in a source file to set an option that cannot be set after either parsing or compiling of the file starts. Instead, set this option on the command line or in a `.cfg` file.

For example, if a source file contains a `#pragma option push –v`, you need to remove the push or set /unset this option either on the command line or in a `.cfg` file.

3.1.2.13 E2528: Option 'name' must be set before compilation begins (C++)

An attempt was made in a source file to set an option that must be set before compiling starts. Instead, set this option on the command line, in a `.cfg` file, or at the top of the source file before the line `int foo();` .

3.1.2.14 E2074: Value after -g or -j should be between 0 and 255 inclusive (C++)

Both the -g and the -j command line options can be followed by an optional number. The compiler expects this number to be between 0 and 255 inclusive.

3.1.2.15 E2492: Properties may only be assigned using a simple statement, e.g. \"prop = value;\" (C++)

Assignments to properties should be made in simple assignment statements. If property assignments could become Lvalues, which happens when property assignments are embedded in larger statements, the getter is called to create the Lvalue, with all the side effects that getter causes. The compiler allows only one call to either the getter or the setter in a statement.

For example:

```
class myClass
{
  int X;
  public:
  int __property x = { read=getx, write=putx };
  int getx() { return X; }
  void putx(int val) { X = val; }
} OneClass;
int value(int);
int main()
{
  return value(OneClass.x = 4);  // This causes an error
}
```

3.1.2.16 E2505: Explicit instantiation requires an elaborated type specifier (i.e.,"class foo<int>") (C++)

The following code is illegal:

```
template<class T> class foo;
template foo<int>;            // missing `class' keyword
```

See Also

Implicit And Explicit Template Functions (see page 434)

3.1.2.17 E2100: Invalid template declarator list (C++)

It is illegal for a declarator list to follow a template class declaration. For example:

```
template<class T>
class foo {
} object_name;  // This causes an error
```

3.1.2.18 E2102: Cannot use template 'template' without specifying specialization parameters (C++)

The generic form of a template must be referenced using specialization parameters. For example, for a template class named foo, taking two template parameters, then a legal reference might have the form

```
foo<int, char>
```

Referring to the template as just foo is legal in only two circumstances:

- When passing the template name as a template template argument
- While declaring the members of that class template, to refer to the enclosing template type

For example:

```
template<class T>
class foo
{
public:
    foo();       // legal use of bare template name
    foo& operator=(const foo&);
};
foo<foo> x;   // error: not a template template argument
foo y;    // error: needs specialization parameters
```

3.1.2.19 E2107: Invalid use of template 'template' (C++)

This error results when attempting to use a template template parameter in any way other than to reference a template specialization, or to pass that parameter in turn as a template template argument to another template. For example:

```
template<template<class T> class U>
class foo;
template<template<class T> class U>
class bar
{
U x;// error: not a specialization
U<U> y;// ok: used as a specialization, and as a
// template template argument
U<bar> z;// ok: used to reference a specialization
};
```

3.1.2.20 E2105: 'template' qualifier must specify a member template name (C++)

When parsing code that depends in some way upon a template parameter, it is sometimes impossible to know whether a member name will resolve to a template function name, or a regular parameter. In the following code, a 'template' qualifier is required in order to know if the '<' (less-then) operator should be parsed as the beginning character of a template argument list, or as a regular less-than operator:

```
template<class T>
void foo(T a)
{
a.member<10>();
}
```

Although it may be apparent to the reader what is meant, the compiler does not know that "member" refers to a member template function, and it will parse the line of code as follows:

```
a.member < (10>());
```

In order to tell the compiler that the less-than character begins a template argument list, the 'template' qualifier is needed:

```
a.template member<10>();   // "member" must be a member template
```

If the 'template' qualifier is used in a situation where "member" does not resolve to a member template, the above error will result.

3.1.2.21 E2066: Information not available (C++)

Help is not available for this item.

3.1.2.22 E2471: pragma checkoption failed: options are not as expected (C++)

You can use #pragma checkoption to check that certain switches are in the state that you expect. If #pragma checkoption detects that a switch is not in the expected state, the compiler displays this error.

You can use the following syntax:

```
#pragma checkoption <options>
```

For example:

```
#pragma checkoption -O2
```

OR

```
#pragma checkoption -C -O2
```

The compiler will check if the option(s) are turned on. If all are turned on, nothing happens. If at least one is not turned on, this error is displayed.

3.1.2.23 E2504: 'dynamic' can only be used with non-template member functions (C++)

You tried to use dynamic with a template member function. Dynamic functions are allowed for classes derived from TObject. Dynamic functions occupy a slot in every object that defines them, not in any descendants. That is, dynamic functions are virtual functions stored in sparse virtual tables. If you call a dynamic function, and that function is not defined in your object, the virtual tables of its ancestors are searched until the function is found.

3.1.2.24 E2191: '__far16' may only be used with '__pascal' or '__cdecl' (C++)

This is an internal compiler error. The compiler emits this message if the keyword __far16 is mixed with one of the keywords __pascal or __cdecl, all in the same declaration.

3.1.2.25 E2199: Template friend function 'function' must be previously declared (C++)

Not used

3.1.2.26 E2502: Error resolving #import: problem (C++)

Where `problem` can be any of the following relating to problems with the various attributes of #include (see page 692):

unexpected import directive value attribute 'attribute'A value was supplied for the indicated attribute. None was expected.

missing ')' in import directive attribute 'attribute'The value for the indicated attribute was incorrectly specified : a closing parenthesis is missing.

unrecognized import directive attribute 'attribute'The indicated token is not a legitimate attribute for the #import directive.

invalid values for raw_property_prefixes attributeThe values for the raw_property_prefixes attribute were incorrectly specified.

unexpected duplicate property 'property'The indicated #import attribute was specified more than once -- this is an error.

unexpected duplicate get method for property 'property'The get method for the indicated property was specified more than once.

unexpected duplicate put method for property 'property'The put method for the indicated property was specified more than once.

unexpected duplicate put-reference method for property 'property'The put-reference method for the indicated property was specified more than once.

no return value specified for property get method 'method'The indicated property get method does not supply the correct return type.

no return value specified for property put method 'method'The indicated property put method does not supply the correct return type.

could not load type library in 'filename'The indicated type library could not be opened.

could not obtain type library nameThe compiler could not obtain obtain a library name for the current type library

See Also

#include (see page 692)

3.1.2.27 E2501: Unable to open import file 'filename' (C++)

This error occurs when you use:

```
#import "somefile.h"
```

and the file you are trying to import doesn't exist or can't be found by the compiler.

3.1.2.28 E2494: Unrecognized __declspec modifier (C++)

A _declspec modifier was given that is not valid.

3.1.2.29 E2493: Invalid GUID string (C++)

The GUID string does not have the form of a Globally Unique Identifier.

3.1.2.30 E2499: Invalid __declspec(uuid(GuidString)) format (C++)

This error happens when you used the wrong format to define your GuidString. GUIDs are defined for structs in the following way:

```
class __declspec(uuid("19a76fe0-7494-11d0-8816-00a0c903b83c")) foo{};
```

You would get the above mentioned error for instance from:

```
class __declspec(uuid(19a76fe0-7494-11d0-8816-00a0c903b83c)) foo{}; //Missing quotes
```

or

```
class __declspec(uuid"7494-11d0-8816-00a0c903b83c")) foo{}; // Missing left parentheses
```

3.1.2.31 E2496: Invalid call to uuidof(struct type|variable) (C++)

The uuidof operator was given an incorrect argument.

3.1.2.32 E2511: Unterminated macro argument (C++)

A macro argument that was started on the line listed has not been properly terminated

3.1.2.33 E2489: Maximum option context replay depth exceeded; check for recursion (C++)

If this error is triggered, it means that recursive template instantiation has gone too deep. Check for compile-time recursion in your program, and limit it to no more than 256 levels.

3.1.2.34 E2488: Maximum token reply depth exceeded; check for recursion (C++)

If this error is triggered, it means that recursive template instantiation has gone too deep. Check for compile-time recursion in your program, and limit it to no more than 256 levels.

3.1.2.35 E2491: Maximum VIRDEF count exceeded; check for recursion (C++)

Too many VIRDEF symbols were allocated. The compiler imposes a limit to the number of VIRDEFs allowed per translation unit. Currently this limit is in the order of 16384 VIRDEFs.

One way this could happen is if a program has more than 16384 functions.

3.1.2.36 E2230: In-line data member initialization requires an integral constant expression (C++)

Static const class members, which are initialized in the body of the class, have to be initialized with a constant expression of integral type.

3.1.2.37 E2241: VCL style classes need virtual destructors (C++)

Destructors defined in VCL style classes have to be virtual.

Example

```
struct __declspec(delphiclass) vclclass1
{
~vclclass1() {}           // Error
};
struct __declspec(delphiclass) vclclass2
{
virtual ~vclclass2() {}   // OK
};
```

3.1.2.38 E2524: Anonymous structs/unions not allowed to have anonymous members in C++ (C++)

The C++ compiler requires that the members of an anonymous struct or union be named.

3.1.2.39 E2246: x is not abstract public single inheritance class hierarchy with no data (C++)

Internal compiler error. In some cases, the compiler will enforce restrictions on a class hierarchy. In this case, the restrictions would be that all classes are abstract classes, and all classes only have one parent.

3.1.2.40 E2249: = expected (C++)

The compiler expected an equal sign in the position where the error was reported but there was none. This is usually a syntax error or typo.

3.1.2.41 E2267: First base must be VCL class (C++)

Internal compiler error. In some cases, the compiler will enforce restrictions on a class hierarchy. In this case, the restrictions would be that the first parent of a class is a Delphi style class.

3.1.2.42 E2472: Cannot declare a member function via instantiation (C++)

If a declaration within a template class acquires a function type through a type dependent on a template-parameter and this results in a declaration that does not use the syntactic form of a function declarator to have function type, the program is ill-formed. For example:

```
template<class T>
struct A {
static T t;
};
typedef int function();
A<function> a;// error: would declare A<function>::t
// as a static member function
```

Another example:

In the example below, the template member 'a' has type 'T'. If the template is instantiated with T as a function type, it implies that 'a' is therefore a member function. This is not allowed and the error message is displayed.

```
template<T& x> class foo { T a; }
int func(int);
template class foo<func>;
```

3.1.2.43 E2515: Cannot explicitly specialize a member of a generic template class (C++)

You are trying to make a generic template into a specialized member. For example, the following code is illegal:

```
    template<typename T>
class foo {
template<typename U>
      class bar {
      };
    };
template<typename T>
template<>
class foo<T>::bar<char> {
};
```

The second declaration in the example is an error, because it tries to explicitly specialize bar<char> within foo<T>.

3.1.2.44 E2474: 'function' cannot be declared as static or inline (C++)

You attempted to declare a symbol as static or inline and this type of symbol cannot be defined as static or inline. Certain functions, like 'main' and 'WinMain' cannot be declared static or inline. 'main' is the entrypoint of console applications, and 'WinMain' is the entry point of Windows applications.

For example, this error is displayed in the following cases:

```
static int main()  // This causes an error
{}
```

or

```
inline int main() { return 0; }
```

3.1.2.45 E2498: Need previously defined struct GUID (C++)

This happens when you use the __uuidof operator without including a header that defines the GUID struct. So the following program code would display this error:

```
class __declspec(uuid("19a76fe0-7494-11d0-8816-00a0c903b83c")) foo{};
int main()
{
    __uuidof(foo);
    return 0;
}
```

And you would fix it as follows:

```
#include <windows.h>    // Will pull in struct GUID
class __declspec(uuid("19a76fe0-7494-11d0-8816-00a0c903b83c")) foo{};
int main()
{
    __uuidof(foo);
    return 0;
}
```

3.1.2.46 E2295: Too many candidate template specializations from 'specifier' (C++)

When reference a class template specialization, it is possible that more than one possible candidate might result from a single reference. This can only really happen among class partial specializations, when more than one partial specialization is contending for a possible match:

```
template<class T, class U>
class foo;
template<class T>
class foo<T, T *>;
template<class T>
class foo<T *, T>;
foo<int *, int *> x;  // error: which partial specialization to use?
```

In this example, both partial specializations are equally valid, and neither is more specialized than the other, so an error would result.

3.1.2.47 E2475: 'function' cannot be a template function (C++)

Certain functions, like 'main' and 'WinMain' cannot be declared as a template function. 'main' is the entrypoint of console applications, and 'WinMain' is the entry point of Windows applications.

For example:

```
template <class T> int main()  // This causes an error
{}
```

See Also

Function Templates (see page 433)

3.1.2.48 E2299: Cannot generate template specialization from 'specifier' (C++)

This error will result if an attempt is made to reference a template class or function in a manner which yields no possible candidate specializations. For example:

```
template<class T>
class foo;
foo<10> x;       // error: arguments aren't valid for 'foo'
```

3.1.2.49 E2300: Could not generate a specialization matching type for 'specifier' (C++)

This error is no longer generated by the compiler.

3.1.2.50 E2497: No GUID associated with type:'type' (C++)

A variable or type was used in a context requiring a GUID, but the type does not have a GUID associated with it. GUIDs are associated with types using _declspec (uuid(GUID)).

3.1.2.51 E2522: Non-const function 'function' called for const object (C++)

Data type mismatch resulting in an erroneous function call. The object of the call (a non-const function) should be a const object.

3.1.2.52 E2523: Non-volatile function 'name' called for volatile object (C++)

Data type mismatch. The error is the result of an erroneous function call. The object of the call (a non-volatile function) should be a volatile object.

3.1.2.53 E2513: Cannot emit RTTI for 'parameter' in 'function' (C++)

The compiler issues this error if it cannot generate RTTI information for the return type of a parameter. See Runtime type information for more information.

3.1.2.54 E2512: Cannot emit RTTI for return type of 'function' (C++)

The compiler issues this error if the it cannot generate RTTI information for the return type of a function. See Runtime type information for more information.

3.1.2.55 E2507: 'class' is not a direct base class of 'class' (C++)

The first type is not a direct base class of the second type. A direct base class refers to the immediate derivations of that class, and not the derivations of its subclasses.

3.1.2.56 E2529: Path 'path' exceeds maximum size of 'n' (C++)

In looking up include files, the C++ compiler has encountered a file whose path name contains more characters than are allowed in the Windows maximum. Rename the path to a shorter name.

3.1.2.57 E2495: Redefinition of uuid is not identical (C++)

GUID's attached to structs have to be the same across multiple declarations and definitions of the same struct. So the following example would cause this error:

```
class __declspec(uuid("19a76fe0-7494-11d0-8816-00a0c903b83c")) foo;
class __declspec(uuid("00000000-7494-11d0-8816-00a0c903b83c")) foo{}
```

3.1.2.58 E2500: __declspec(selectany) is only for initialized and externally visible variables (C++)

You cannot use __declspec(selectany) with static variables, unitialized variables, etc.

3.1.2.59 E2482: String constant expected (C++)

The compiler expected a string constant at this location but did not receive one.

This error is no longer generated by the compiler.

3.1.2.60 E2481: Unexpected string constant (C++)

There are times when the compiler does not expect a string constant to appear in the source input. For example:

```
class foo { "Hello"; };
```

3.1.2.61 E2386: Cannot involve parameter 'parameter' in a complex partial specialization expression (C++)

When declaring or defining a template class partial specialization, it is illegal to involve any of the non-type template parameters in complex expressions. They may only be referenced by name. For example:

```
template<class T, int U>
class foo;
template<int U>
class foo<char, U * 3>;// error: "U * 3" is a complex expression
template<int U>
class foo<char, U>;// OK: "U" is a simple, by-name expression
```

3.1.2.62 E2387: Partial specializations may not specialize dependent non-type parameters ('parameter') (C++)

A partial specialization may not use a template parameter in its specialization argument list which is dependent on another type parameter. For example:

```
template<class T, int U>
class foo;
template<class T, T U>
class foo<T *, U>;      // error: 'U' is type-dependent
```

3.1.2.63 E2388: Argument list of specialization cannot be identical to the parameter list of primary template (C++)

When declaring a partial specialization, its specialization argument list must differ in some way from its basic parameter list. For example:

template<class T>

```
class foo;
template<class T>
class foo<T *>;     // OK: is more specialized than primary template
template<class T>
class foo<T>;       // error: identical to primary template
```

3.1.2.64 E2389: Mismatch in kind of substitution argument and template parameter 'parameter' (C++)

When referencing a template specialization, all type parameters must be satisfied using type arguments, all non-type parameters require non-type arguments, and all template template parameters require either a template name, or another template template argument. Mismatching these requirements in any way will trigger the above error. For example:

```
template<class T, int U, template<class V> class W>
class foo;
foo<char, 10, foo> x;    // OK: all parameter kinds match
foo<10, char, int> y;    // error: no parameter kinds match at all!
```

3.1.2.65 E2480: Cannot involve template parameters in complex partial specialization arguments (C++)

A partial specialization cannot reference other template parameters in a nonvalue argument expression, unless it is simply a direct reference to the template parameter. For example:

```
template<int A, int B, int C> class foo;
template<int A> class foo<A+5, A, A+10>;
```

The partial specialization has two illegal arguments. 'A+5' is a complex expression because it uses 'A' in a manner other than as merely a direct argument. The reference to plain 'A' in the second argument is fine, but the third argument is also illegal because it references 'A' in a complex manner as well.

3.1.2.66 E2392: Template instance 'template' is already instantiated (C++)

There are two ways to trigger this error. If –A is enabled (ANSI compliant mode), then attempting to explicitly instantiate a template specialization which has already been instantiated (either implicitly or explicitly) will cause this error. Regardless of –A, attempting to explicitly specialize a template specialization which has already been either implicit or explicitly instantiated will always trigger this error. For example:

```
template<class T>
class foo;
foo<char> x;     // causes implicit instantiation of "foo<char>"
template<>
class foo<char> { };   // error: "foo<char>" already instantiated
template class foo<char>;   // error in –A mode, otherwise a warning
```

3.1.2.67 E2393: Cannot take the address of non-type, non-reference template parameter 'parameter' (C++)

A template parameter has no address, and is not associated with any real "object". Therefore, to take its address, or attempt to assign to it, has no meaning. For example:

```
template<int U>
void foo()
{
int *x = &U;// error: cannot take address of parameter
}
```

3.1.2.68 E2399: Cannot reference template argument 'arg' in template class 'class' this way (C++)

The compiler no longer generates this error.

3.1.2.69 E2397: Template argument cannot have static or local linkage (C++)

Only integral constant expressions, and the address of global variables with external linkage, may be used as template arguments. For example:

```
template<char *x>
class foo;
const char *p = "Hello";
extern char *q;
foo<p> x;// OK: "p" is visible to the outside
foo<q> y;// OK: "q" is also globally visible
foo<"Hello"> z;// error: string literal has static linkage
```

3.1.2.70 E2485: Cannot use address of array element as non-type template argument (C++)

Non-type template arguments may only be of integral type, or the address of a global variable. They cannot be the address of an array element. For example:

```
int x[100];
template<int T>
class foo;
foo<&x[0]> y;// error: not an integral or global address
```

3.1.2.71 E2402: Illegal base class type: formal type 'type' resolves to 'type' (C++)

When instantiating a template class definition, if it is found that a declared base class does not resolve to an accessible class type, this error will result. For example:

```
template<class T>
class foo : public T { };
foo<int> x;// error: "int" is not a valid base class
foo<bar> y;// error: "bar" is an unknown type
```

3.1.2.72 E2403: Dependent call specifier yields non-function 'name' (C++)

The compiler no longer generates this error.

3.1.2.73 E2404: Dependent type qualifier 'qualifier' has no member type named 'name' (C++)

If a template declaration references a member of a dependent type, it is only possible to alert the user to the non-existence of this member during type instantiation for a given set of template arguments. For example:

```
template<class T>
class foo
{
typename T::A x;     // we expect that "A" is a member type
};
struct bar { };
foo<bar> y;// error: "bar" has no member type named "A"
```

3.1.2.74 E2405: Dependent template reference 'identifier' yields non-template symbol (C++)

If a template specialization reference within a template declaration yields a reference to a non-template during type instantiation, the above error will result. For example:

```
template<class T>
class foo
{
```

```
typename T::template A<int> x;  // "A" must be a member template
};
struct bar {
struct A { };
};
foo<bar> y;// error: bar::A is a non-template class!
```

3.1.2.75 E2406: Dependent type qualifier 'qualifier' is not a class or struct type (C++)

If a dependent name reference within a template declaration results in a non-struct member qualification at instantiation time, the above error will result. For example:

```
template<class T>
class foo
{
typename T::A x;     // we expect that "A" is a member type
};
foo<int> y;// error: "int" cannot be qualified; not a class
```

3.1.2.76 E2407: Dependent type qualifier 'qualifier' has no member symbol named 'name' (C++)

If a template declaration references a member of a dependent type, it is only possible to alert the user to the non-existence of this member during type instantiation for a given set of template arguments. For example:

```
template<class T>
class foo
{
foo(int *a = T::A);     // we expect that "A" is a data member
};
struct bar { };
foo<bar> y;// error: "bar" has no member named "A"
```

3.1.2.77 E2408: Default values may be specified only in primary class template declarations (C++)

Template functions, and class partial specializations, may not use default expressions in their template parameter lists. Only primary template declarations may do this. For example:

```
template<class T = int>
class foo;// OK: primary class template
template<class T = int>
void bar();// error: template function
template<class T = int>
class foo<T *>;// error: partial specialization
```

3.1.2.78 E2409: Cannot find a valid specialization for 'specifier' (C++)

This error is no longer generated by the compiler.

3.1.2.79 E2410: Missing template parameters for friend template 'template' (C++)

If a friend template is declared, but no template parameters are specified, this error will result. For example:

```
template<class T>
class foo;
class bar {
friend class foo;// error: forgot template parameters!
};
```

3.1.2.80 E2486: Cannot use address of class member as non-type template argument (C++)

Non-type template arguments may only be of integral type, or the address of a global variable. They cannot be the address of a class member. For example:

```
struct bar {
int x;
} y;
template<int T>
class foo;
foo<&y.x> z;// error: not an integral or global address
```

3.1.2.81 E2411: Declaration of member function default parameters after a specialization has already been expanded (C++)

If a member function of a class template is declared, and then a specialization of that class implicitly instantiated, and later that member function defined with default parameters specified, the above error will result. For example:

```
template<int i>
class foo {
void method(int a, int b = i);
};
foo<10> x;
template<int i>
void foo<i>::method(int a = i, int b);  // error!
```

3.1.2.82 E2412: Attempting to bind a member reference to a dependent type (C++)

The compiler no longer generates this error.

3.1.2.83 E2414: Destructors cannot be declared as template functions (C++)

Destructors cannot be templates. For example:

```
class foo {
template<class T>
virtual ~foo();// error: don't try this at home!
```

```
};
```

3.1.2.84 E2473: Invalid explicit specialization of 'specifier' (C++)

Attempting to explicitly specialize a static data member or any non-template will cause this error.

3.1.2.85 E2490: Specialization within template classes not yet implemented (C++)

Explicit and partial specialization of member template classes and functions within template classes and nested template classes, is not supported.

3.1.2.86 E2416: Invalid template function declaration (C++)

The compiler no longer generates this error.

3.1.2.87 E2417: Cannot specify template parameters in explicit specialization of 'specifier' (C++)

The compiler no longer generates this error.

3.1.2.88 E2418: Maximum instantiation depth exceeded; check for recursion (C++)

The compiler only supports 256 levels of instantiation before it will trigger this error. The main problem is in controlling stack depth, because the parser uses recursive functions to manage type instantiation. Here is an example that would produce such an error:

```
template<int T>
class foo {
public:
static const int x = foo<T – 1>::x;
};
template<int T>
class foo<1> {
public:
static const int x = 1;
};
int main() {
int y = foo<100000>::x;// error: instantiation depth exceeded
}
```

3.1.2.89 E2420: Explicit instantiation can only be used at global scope (C++)

Explicit instantiation cannot be specified at any level other than namespace or global scope. For example:

```
template<class T>
```

```
class foo { };
template class foo<char>;// OK: at global scope
int main() {
template class foo<int>:// error: local scope
}
```

3.1.2.90 E2422: Argument kind mismatch in redeclaration of template parameter 'parameter' (C++)

If a template is declared at one point in the translation unit, and then redeclared with template parameters of a different kind at another location, this error will result. For example:

```
template<class T>
class foo;
// ? time passes ?
template<int T>
class foo;// error: type vs. non-type parameter
```

3.1.2.91 E2423: Explicit specialization or instantiation of non-existing template 'template' (C++)

Attempting to explicit specialize or instantiate a template which does not exist is clearly illegal. For example:

```
template<class T>
class foo;
template class bar<char>;// error: what is "bar"??
template<>
class bar<int> { };// error: there's that "bar" again?
```

3.1.2.92 E2479: Cannot have both a template class and function named 'name' (C++)

No other function or type may have the same name as a template class. For example:

```
void foo();// error: there is a template class named "foo"
template<class T>
class foo;
```

3.1.2.93 E2484: The name of template class 'class' cannot be overloaded (C++)

Attempting to declare a function that overrides the name of a template class will cause this error. For example:

```
template<class T>
class foo;
void foo();// error: there is a template class named "foo"
```

3.1.2.94 E2426: Explicit specialization of 'specifier' requires 'template<>' declaration (C++)

According to the standard, explicit specialization of any template now always require the "template<>" declarator syntax. For example:

```
template<class T>
class foo;
template<>
class foo<char>;// OK: "template<>" was provided
class foo<int>;// error: "template<>" required
```

3.1.2.95 E2487: Cannot specify default function arguments for explicit specializations (C++)

An explicit specialization of a function may not declare default function arguments. For example:

```
template<class T>
void foo(T a);
template<>
void foo<int>(int a = 10);// error: default value not allowed
```

3.1.2.96 E2427: 'main' cannot be a template function (C++)

'main' cannot be declared as a template function. 'main' is the entry point of a console application, and it should be declared as a regular __cdecl function.

This error message should not occur because it has been replaced with another one (E2475).

3.1.2.97 E2429: Not a valid partial specialization of 'specifier' (C++)

Internal compiler error.

3.1.2.98 E2430: Number of template parameters does not match in redeclaration of 'specifier' (C++)

If a template is redeclared with a different number of template parameters, this error will result. For example:

```
template<class T>
class foo;
template<class T, int U>
class foo;// error: parameter count mismatch!
```

3.1.2.99 E2477: Too few template parameters were declared for template 'template' (C++)

If a member declaration or definition occurs outside of a template class, and that outer declaration uses a different number of template parameters than the parent class, this error will result. For example:

```
template<class T, class U>
class foo {
void method();
};
template<class T>
void foo<T>::method() { }// error: too few template parameters!
```

3.1.2.100 E2478: Too many template parameters were declared for template 'template' (C++)

If a member declaration or definition occurs outside of a template class, and that outer declaration uses a different number of template parameters than the parent class, this error will result. For example:

```
template<class T, class U>
class foo {
void method();
};
template<class T, class U, class V>
void foo<T, U, V>::method() { }// error: too many parameters!
```

3.1.2.101 E2431: Non-type template parameters cannot be of floating point, class, or void type (C++)

Non-type template parameters are restricted as to what type they may be. Floating point, class and void types are illegal. For example:

```
template<float U>
class foo;// error: "U" cannot be of "float" type
```

3.1.2.102 E2434: Template declaration missing template parameters ('template<...>') (C++)

In a context where at least one template parameter is clearly required, if none are found this error will result. For example:

```
template<class T, template<> class U>
class foo;// error: template template parameters require
// at least one actual parameter to be declared
```

3.1.2.103 E2435: Too many template parameter sets were specified (C++)

If a member template is being defined outside of its parent class, and too many template parameter sets are declared, this error will result. For example:

```
template<class T>
class foo
{
template<class U>
void method(U a);
};
template<class T> template<class U> template<class V>
void foo<T>::method(U a);// error: too many parameter sets!
```

3.1.2.104 E2436: Default type for template template argument 'arg' does not name a primary template class (C++)

If a template template parameter is to have a default type, that type must either be a generic template class name, or another template template parameter.

```
template<class T>
class foo;
template<template<class T> class U = foo>
class bar;// OK: "foo" is a qualifying primary template
template<template<class T> class U = int>
class baz;// error: "int" is not a template class
```

3.1.2.105 E2437: 'typename' should be followed by a qualified, dependent type name (C++)

Whenever the "typename" keyword is used in a template declaration or definition, it should always name a dependent type. For example:

```
struct bar { };
template<class T>
class foo {
typename T::A *x;// OK: names a qualified type
typename T y;// error: not a qualified type
typename bar z;// error: not a dependent type
};
```

3.1.2.106 E2438: Template template arguments must name a class (C++)

A template template parameter must always declare a new class name. For example:

```
template<template<class T> int U>
class foo;// error: "U" is not a class tag name
template<template<class T> class V>
class bar;// OK: "V" is a class tag name
```

3.1.2.107 E2439: 'typename' is only allowed in template declarations (C++)

The "typename" keyword must only be used within template declarations and definitions.

3.1.2.108 E2440: Cannot generate specialization from 'specifier' because that type is not yet defined (C++)

The compiler no longer generates this error.

3.1.2.109 E2441: Instantiating 'specifier' (C++)

Whenever a compiler error occurs while instantiating a template type, the context of what was being instantiated at that point in time will be reported to the user, in order to aid in detection of the problem.

3.1.2.110 E2503: Missing or incorrect version of TypeLibImport.dll (C++)

This error occurs when the compiler is trying to access TypeLibImport.dll but it either can't find it, it was corrupted, or you have the wrong version of it installed on your computer. You can reinstall it from the product CD.

3.1.2.111 E2470: Need to include header <typeinfo> to use typeid (C++)

When you use the 'typeid' function, you have to include the <typeinfo> header, otherwise you will get syntax errors.

For example, consider a test case with the following code:

```
int func()
{
  char * name = typeid(int).name();  // This causes an error
}
```

3.1.2.112 E2514: Cannot (yet) use member overload resolution during template instantiation (C++)

You are trying to overload a member during template instantiation. You cannot have calls to overloaded constant functions within array bounds initializers, for example.

3.1.2.113 E2508: 'using' cannot refer to a template specialization (C++)

The `using` keyword cannot refer to a template specialization.

3.1.2.114 E2462: 'virtual' can only be used with non-template member functions (C++)

The 'virtual' keyword can only be applied to regular member functions, not to member template functions.

Consider a test case with the following code:

```
template <class T>
class myTemplateClass
{
  virtual int func1();                    // This is fine
  template <class T> virtual int func2(); // This causes an error
};
class myClass
{
  virtual int func1();                    // This is fine
  template <class T> virtual int func2(); // This causes an error
};
```

3.1.2.115 W8086: Incorrect use of #pragma alias "aliasName"="substituteName" (C++)

The directive #pragma alias is used to tell the linker that two identifier names are equivalent. You must put the two names in quotes.

You will receive this warning if you don't use pragma alias correctly. For example, the following two lines both generate this warning:

```
#pragma alias foo=bar
#pragma alias "foo" = bar
```

See the “#pragma alias” reference below for information on this pragma's usage.

See Also

#pragma (see page 696)

3.1.2.116 W8099: Static main is not treated as an entry point (C++)

The main function has been created as static, and as such cannot be used as a valid entry point.

Consider:

```
static void main(int argc, char**argv)
{
}
```

The above is valid C syntax, but cannot actually be called as the startup routine since it has been declared static.

3.1.2.117 W8093: Incorrect use of #pragma codeseg [seg_name] ["seg_class"] [group] (C++)

The #pragma codeseg directive can be used to set or reset the name, class, and group of a segment. You have to follow the exact syntax mentioned in the warning message, and all names are optional.

So these are all legal:

```
#pragma codeseg
#pragma codeseg foo
#pragma codeseg foo "bar"
#pragma codeseg foo "bar" foobar
```

But these are not:

```
#pragma codeseg ###
#pragma codeseg "foo" "bar"
#pragma codeseg foo "bar" foobar morefoobar
```

3.1.2.118 W8094: Incorrect use of #pragma comment(<type> [,"string"]) (C++)

The directive #pragma comment can be used to emit linker comment records.

In this message, <type> can be any of the following:

- user
- lib
- exestr
- linker

The type should be there but the string is optional.

3.1.2.119 W8085: Function 'function' redefined as non-inline (C++)

This warning is used to indicate when a certain function, which has been declared inline in one location, is redefined in another location to be non-inline.

3.1.2.120 W8105: %s member '%s' in class without constructors (C++)

A class that contains constant or reference members (or both) must have at least one user-defined constructor.

Otherwise, there would be no way to ever initialize such members.

3.1.2.121 W8095: Incorrect use of #pragma message("string") (C++)

You can use pragma message to emit a message to the command line or to the message window. You would get this warning if you use the incorrect syntax, so

```
#pragma message( "hi there" )
```

is correct, but the following code would generate the warning:

```
#pragma message( badly formed )
```

3.1.2.122 W8098: Multi-character character constant (C++)

This warning is issued when the compiler detects a multi-character integer constant, such as:

```
int foo = 'abcd';
```

The problem with this construct is that the byte order of the characters is implementation dependent.

3.1.2.123 W8096: Incorrect use of #pragma code_seg(["seg_name"[,"seg_class"]]) (C++)

Pragma code_seg is similar to pragma codeseg, but with this one you can only modify the name and the class of a code segment. If you use the wrong syntax, you get this warning.

The following examples show the correct usage:

```
#pragma code_seg()
#pragma code_seg("foo")
#pragma code_seg("foo", "bar")
```

However, the following incorrect examples will all produce the warning:

```
#pragma code_seg(foo)
#pragma code_seg(foo, bar)
```

3.1.2.124 W8083: Pragma pack pop with no matching pack push (C++)

Each #pragma pack(pop) should have a matching preceding #pragma pack(push) in the same translation unit. Pairs of 'push' and 'pop' can be nested.

For example:

```
#pragma pack( push )
#pragma pack( push )
#pragma pack( pop )
#pragma pack( pop )
#pragma pack( pop )   // This causes an error
```

3.1.2.125 W8097: Not all options can be restored at this time (C++)

Your program has a #pragma pop at a place where it can't restore options.

For example:

```
#pragma option push -v
int main()
{
  int i;
  i = 1;
#pragma option pop
  return i;
}
```

For this example, compile with -v-. The message happens because the first #pragma causes debug info to change state (turns it on). Then, in the middle of the function where it is useless to toggle the debug info state, the #pragma pop attempts to return to the former state.

3.1.2.126 W8084: Suggest parentheses to clarify precedence (C++)

This warning indicates that several operators used in one expression might cause confusion about the applicable operator precedence rules. The warning helps create code that is more easy to understand and potentially less ambiguous.

For example, compile the following code using the `-w` command line option:

```
int j, k, l;
int main()
{
  return j < k & l;  // This causes an error
}
//
```

3.1.2.127 W8092: 'type' argument 'specifier' passed to 'function' is not an iterator: 'type' iterator required (C++)

An argument that is not an iterator is being used with an STL algorithm that requires an iterator.

3.1.2.128 W8087: 'operator::operator==' must be publicly visible to be contained by a 'type' (C++)

A type that is being used with an STL container has a private 'operator==='.

3.1.2.129 W8090: 'type::operator<' must be publicly visible to be used with 'type' (C++)

A type that is being used with an STL container has a private 'operator<'. The type you're trying to use must be made public.

3.1.2.130 W8089: 'type::operator<' must be publicly visible to be contained by a 'type' (C++)

The type that is being used for an STL container has a private 'operator<'. The type that is being contained (type::operator) must be a public type.

For example, if you were trying to instantiate a class type "vector<blah>", the error would be:

```
'blah::operator<' must be publicly visible to be contained by a 'vector'
```

3.1.2.131 W8091: 'type' argument 'specifier' passed to 'function' is a 'iterator category' iterator: 'iterator category' iterator required (C++)

An incorrect iterator category is being used with an STL algorithm.

3.1.2.132 W8076: Template instance 'specifier' is already instantiated (C++)

You are trying to explicitly instantiate a template that was already implicitly instantiated.

If –A is not enabled and an attempt is made to explicitly instantiate a specialization which has already been either implicitly or explicitly instantiated, this error will result.

3.1.2.133 W8077: Explicitly specializing an explicitly specialized class member makes no sense (C++)

Internal error. This warning is no longer generated by the compiler.

The following code is illegal:

```
template<class T> class foo { int x; }
template<> class foo<int> { int y; }
template<> int foo<int>::y;   // error: cannot explicitly specialize of 'foo<int>::x'
```

3.1.2.134 Informational messages (C++)

The compiler displays status information while compiling if you have checked "Show general messages" on the Compiler page of the Project Options dialog box. Most of the messages are self-explanatory and state information about compiling and linking; for example:

```
[C++] Compiling: D:\Program Files\Borland\CBuilder\Bin\Unit1.cpp
```

You may also see a message such as

```
[C++] Including clx.h instead of clx.h due to -Hr switch
```

This message indicates that the IDE-managed precompiled header file was replaced due to additional CLX classes being included in the project. It does not indicate a failure condition. Sometimes the header file name being included may be the same if it is being included with a different #define statement.

3.1.2.135 E2196: Cannot take address of member function 'function' (C++)

An expression takes the address of a class member function, but this member function was not found in the program being debugged. The evaluator issues this message.

3.1.2.136 F1002: Unable to create output file 'filename' (C++)

This error occurs if the work disk is full or write protected.

This error also occurs if the output directory does not exist.

Solutions

If the disk is full, try deleting unneeded files and restarting the compilation.

If the disk is write-protected, move the source files to a writeable disk and restart the compilation.

3.1.2.137 F1003: Error directive: 'message' (C++)

This message is issued when an `#error` directive is processed in the source file.

'message' is the text of the `#error` directive.

3.1.2.138 F1004: Internal compiler error (C++)

An error occurred in the internal logic of the compiler. This error shouldn't occur in practice, but is generated in the event that a more specific error message is not available.

3.1.2.139 F1006: Bad call of intrinsic function (C++)

You have used an intrinsic function without supplying a prototype. You may have supplied a prototype for an intrinsic function that was not what the compiler expected.

3.1.2.140 F1007: Irreducible expression tree (C++)

An expression on the indicated line of the source file caused the code generator to be unable to generate code. Avoid using the expression. Notify CodeGear if an expression consistently reproduces this error.

3.1.2.141 F1009: Unable to open input file 'filename' (C++)

This error occurs if the source file can't be found.

Check the spelling of the name. Make sure the file is on the specified disk or directory.

Verify that the proper directory paths are listed. If multiple paths are required, use a semicolon to separate them.

3.1.2.142 F1011: Register allocation failure (C++)

Possible Causes

An expression on the indicated line of the source file was so complicated that the code generator could not generate code for it.

Solutions

Simplify the expression. If this does not solve the problem, avoid the expression.

Notify CodeGear if an expression can consistently reproduce this error.

3.1.2.143 F1012: Compiler stack overflow (C++)

The compiler's stack has overflowed. This can be caused by a number of things, among them deeply nested statements in a function body (for example, if/else) or expressions with a large number of operands. You must simplify your code if this message occurs. Adding more memory to your system will not help.

3.1.2.144 F1013: Error writing output file (C++)

A DOS error that prevents the C++ IDE from writing an .OBJ, .EXE, or temporary file.

Solutions

Make sure that the Output directory in the Directories dialog box is a valid directory.

Check that there is enough free disk space.

3.1.2.145 F1000: Compiler table limit exceeded (C++)

One of the compiler's internal tables overflowed.

This usually means that the module being compiled contains too many function bodies.

This limitation will not be solved by making more memory available to the compiler. You need to simplify the file being compiled.

3.1.2.146 F1005: Include files nested too deep (C++)

This message flags (directly or indirectly) recursive `#include` directives.

3.1.2.147 F1008: Out of memory (C++)

The total working storage is exhausted.

This error can occur in the following circumstances:

- Not enough virtual memory is available for compiling a particular file. In this case, shut down any other concurrent applications. You may also try to reconfigure your machine for more available virtual memory, or break up the source file being compiled into smaller separate components. You can also compile the file on a system with more available RAM.
- The compiler has encountered an exceedingly complex or long expression at the line indicated and has insufficient reserves to parse it. Break the expression down into separate statements.

3.1.2.148 F1010: Unable to open 'filename' (C++)

This error occurs if the specified file can't be opened.

Make sure the file is on the specified disk or directory. Verify the proper paths are listed. If multiple paths are required, use a semicolon to separate them.

3.1.2.149 E2000: 286/287 instructions not enabled (C++)

Use the -2 command-line compiler option to enable 286/287 opcodes. Be aware that the resulting code cannot be run on 8086- and 8088-based machines.

3.1.2.150 Abnormal program termination (C++)

The program called abort because there wasn't enough memory to execute.

This message can be caused by memory overwrites.

3.1.2.151 E2009: Attempt to grant or reduce access to 'identifier' (C++)

A C++ derived class can modify the access rights of a base class member, but only by restoring it to the rights in the base class.

It can't add or reduce access rights.

3.1.2.152 E2011: Illegal to take address of bit field (C++)

It is not legal to take the address of a bit field, although you can take the address of other kinds of fields.

3.1.2.153 E2010: Cannot add or subtract relocatable symbols (C++)

The only arithmetic operation that can be performed on a relocatable symbol in an assembler operand is addition or subtraction of a constant.

Variables, procedures, functions, and labels are relocatable symbols.

3.1.2.154 E2013: 'function1' cannot be distinguished from 'function2' (C++)

The parameter type lists in the declarations of these two functions do not differ enough to tell them apart.

Try changing the order of parameters or the type of a parameter in one declaration.

3.1.2.155 E2014: Member is ambiguous: 'member1' and 'member2' (C++)

You must qualify the member reference with the appropriate base class name.

In C++ class 'class', member 'member' can be found in more than one base class, and it was not qualified to indicate which one you meant.

This applies only in multiple inheritance, where the member name in each base class is not hidden by the same member name in a derived class on the same path.

The C++ language rules require that this test for ambiguity be made before checking for access rights (private, protected, public).

It is possible to get this message even though only one (or none) of the members can be accessed.

3.1.2.156 E2015: Ambiguity between 'function1' and 'function2' (C++)

Both of the named overloaded functions could be used with the supplied parameters.

This ambiguity is not allowed.

3.1.2.157 E2017: Ambiguous member name 'name' (C++)

Whenever a structure member name is used in inline assembly, such a name must be unique. (If it is defined in more than one structure, all of the definitions must agree as to its type and offset within the structures). In this case, an ambiguous member name has been used.

For example:

```
struct A
{
   int a;
   int b;
};
...
asm ax,.a;
```

3.1.2.158 E2019: 'identifier' cannot be declared in an anonymous union (C++)

The compiler found a declaration for a member function or static member in an anonymous union.

Such unions can only contain data members.

3.1.2.159 E2020: Global anonymous union not static (C++)

In C++, a global anonymous union at the file level must be static.

3.1.2.160 E2022: Array size too large (C++)

The declared array is larger than 64K and the 'huge' keyword was not used.

If you need an array of this size, either use the 'huge' modifier, like this:

```
int huge array[70000L];  /* Allocate 140000 bytes */
```

or dynamically allocate it with farmalloc( ) or farcalloc( ), like this:

```
int huge *array = (int huge *) farmalloc (sizeof (int) * 70000); ?? Allocate 140,000 bytes
```

3.1.2.161 E2024: Cannot modify a const object (C++)

This indicates an illegal operation on an object declared to be const, such as an assignment to the object.

3.1.2.162 E2025: Assignment to 'this' not allowed, use X::operator new instead (C++)

In early versions of C++, the only way to control allocation of class of objects was by assigning to the 'this' parameter inside a constructor.

This practice is no longer allowed, because a better, safer, and more general technique is to define a member function operator new instead.

For example:

```
this = malloc(n);
```

3.1.2.163 E2026: Assembler statement too long (C++)

Inline assembly statements can't be longer than 480 bytes.

3.1.2.164 E2001: Constructors and destructors not allowed in __automated section (C++)

Only member function declarations are allowed in __automated sections.

Example

```
struct__declspec(delphiclass) clxclass
{
__automated:
int__fastcall fooInt(int);// OK
clxclass()  {}// Error
};
```

3.1.2.165 E2002: Only __fastcall functions allowed in __automated section (C++)

The calling convention for functions declared in an __automated section must be __fastcall.

Example

```
struct__declspec(delphiclass) clxclass
{
__automated:
int__fastcall fooInt(int);// OK
int__cdecl    barInt(int);// Error
};
```

3.1.2.166 E2003: Data member definition not allowed in __automated section (C++)

Only member function declarations are allowed in __automated sections.

Example

```
struct__declspec(delphiclass) clxclass
{
__automated:
int__fastcall fooInt(int);// OK
intmemInt;// Error
};
```

3.1.2.167 E2004: Only read or write clause allowed in property declaration in __automated section (C++)

Storage specifiers stored, default, and nodefault are not allowed in property declarations in __automated sections.

Example

```
struct__declspec(delphiclass) clxclass
{
int __fastcall Get(void);
__automated:
int __property ip1 = { read = Get };      // OK
int __property ip2 = { read = Get, default = 42 }; // Error
};
```

3.1.2.168 E2005: Redeclaration of property not allowed in __automated section (C++)

If you declare a property in an __automated section it has be a new declaration. Property hoisting is not allowed.

Example

```
struct__declspec(delphiclass) clxbaseclass
{
int __fastcall Get(void);
void __fastcall Set(int);
int __property ip1 = { read = Get, write = Set };
};
structclxderivedclass : clxbaseclass
{
int __fastcall NewGetter(void);
__automated:
__property ip1;// Error
int __property ip2 = { read = Get, write = Set }; // OK
};
```

3.1.2.169 E2027: Must take address of a memory location (C++)

Your source file used the address-of operator (&) with an expression that can't be used that way; for example, a register variable.

3.1.2.170 E2028: operator -> must return a pointer or a class (C++)

The C++ operator -> function must be declared to either return a class or a pointer to a class (or struct or union).

In either case, it must be something to which the -> operator can be applied.

3.1.2.171 E2029: 'identifier' must be a previously defined class or struct (C++)

You are attempting to declare 'identifier' to be a base class, but either it is not a class or it has not yet been fully defined.

Correct the name or rearrange the declarations.

3.1.2.172 E2030: Misplaced break (C++)

The compiler encountered a break statement outside a switch or looping construct.

You can only use break statements inside of switch statements or loops.

3.1.2.173 E2031: Cannot cast from 'type1' to 'type2' (C++)

A cast from type 'ident1' to type 'ident2' is not allowed.

In C++, you cannot cast a member function pointer to a normal function pointer.

For example:

```
class A {
public:
   int myex();
};
typedef int (*fp)();
test()
{
   fp myfp = (fp) &A::myex; //error
   return myfp();
}
```

The reason being that a class member function takes a hidden parameter, the this pointer, thus it behaves very differently than a normal function pointer.

A static member function behaves as normal function pointer and can be cast.

For example:

```
class A {
public:
   static int myex();
};
typedef int (*fp)();
test()
{
   fp myfp = (fp) &A::myex; //ok
   return myfp();
}
```

However, static member functions can only access static data members of the class.

In C

- A pointer can be cast to an integral type or to another pointer.
- An integral type can be cast to any integral, floating, or pointer type.
- A floating type can be cast to an integral or floating type.

Structures and arrays can't be cast to or from.

You usually can't cast from a void type.

In C++

User-defined conversions and constructors are checked for. If one can't be found, the preceding rules apply (except for pointers to class members).

Among integral types, only a constant zero can be cast to a member pointer.

A member pointer can be cast to an integral type or to a similar member pointer.

A similar member pointer points to a data member (or to a function) if the original does. The qualifying class of the type being cast to must be the same as (or a base class of) the original.

3.1.2.174 E2033: Misplaced continue (C++)

The compiler encountered a continue statement outside a looping construct.

3.1.2.175 E2034: Cannot convert 'type1' to 'type2' (C++)

An assignment, initialization, or expression requires the specified type conversion to be performed, but the conversion is not

legal.

In C++, the compiler will convert one function pointer to another only if the signature for the functions are the same. Signature refers to the arguments and return type of the function. For example:

```
myex( int );
typedef int ( *ffp )( float );
test()
{
   ffp fp = myex; //error
}
```

Seeing that myex takes an int for its argument, and fp is a pointer to a function which takes a float as argument, the compiler will not convert it for you.

In cases where this is what is intended, performing a typecast is necessary:

```
myex( int );
typedef int ( *ffp )( float );
test()
{
   ffp fp = (ffp)myex;  //ok
}
```

3.1.2.176 E2036: Conversion operator cannot have a return type specification (C++)

This C++ type conversion member function specifies a return type different from the type itself.

A declaration for conversion function operator can't specify any return type.

3.1.2.177 E2037: The constructor 'constructor' is not allowed (C++)

Constructors of the form

```
  X(X);  //{ Error
};
```

are not allowed.

This is the correct way to write a copy constructor:

```
class X {
  X(const X&);// Copy constructor
};
```

3.1.2.178 E2039: Misplaced decimal point (C++)

The compiler encountered a decimal point in a floating-point constant as part of the exponent.

3.1.2.179 E2041: Incorrect use of default (C++)

The compiler found no colon after the default keyword.

3.1.2.180 E2042: Declare operator delete (void*) or (void*, size_t) (C++)

E2043 Declare operator delete[] (void) or (void*, size_t)*Compiler error

Declare the operator delete with one of the following:

1.A single void* parameter, or

2.A second parameter of type size_t

If you use the second version, it will be used in preference to the first version.

The global operator delete can only be declared using the single-parameter form.

3.1.2.181 E2044: operator delete must return void (C++)

*E2044 operator delete[] must return void*Compiler error

This C++ overloaded operator delete was declared in some other way.

Declare the operator delete with one of the following:

1.A single void* parameter, or

2.A second parameter of type size_t

If you use the second version, it will be used in preference to the first version.

The global operator delete can only be declared using the single-parameter form.

3.1.2.182 E2045: Destructor name must match the class name (C++)

In a C++ class, the tilde (~) introduces a declaration for the class destructor.

The name of the destructor must be same as the class name.

In your source file, the ~ preceded some other name.

3.1.2.183 E2048: Unknown preprocessor directive: 'identifier' (C++)

The compiler encountered a # character at the beginning of a line. The directive name that followed the # was not one of the following:

- define (see page 690)
- else (see page 688)
- endif
- if
- ifdef (see page 688)
- ifndef (see page 688)
- include (see page 692)

- line (see page 693)
- pragma
- undef (see page 692)

3.1.2.184 E2046: Bad file name format in include directive OR Bad file name format in line directive (C++)

Include and line directive file names must be surrounded by quotes ("filename.h") or angle brackets (<filename.h>).

The file name was missing the opening quote or angle bracket.

If a macro was used, the resulting expansion text is not surrounded by quote marks.

3.1.2.185 E2051: Invalid use of dot (C++)

An identifier must immediately follow a period operator (.). This is a rare message that can only occur in some specialized inline assembly statements.

Example

```
struct foo {
  int x;
  int y;
}p = {0,0};
int y;
int main (void)
{
  asm mov eax.(foo)x, 1;
  asm mov eax.(foo)4, 1;       /* Error: Invalid use of dot */
  return 0;
}
```

3.1.2.186 E2053: Misplaced elif directive (C++)

The compiler encountered an `#elif` directive without any matching `#if`, `#ifdef`, or `#ifndef` directive.

3.1.2.187 E2054: Misplaced else (C++)

The compiler encountered an `else` statement without a matching if statement.

Possible Causes

- An extra "else" statement
- An extra semicolon
- Missing braces
- Some syntax error in a previous "if" statement

3.1.2.188 E2055: Misplaced else directive (C++)

The compiler encountered an `#else` directive without any matching `#if`, `#ifdef`, or `#ifndef` directive.

3.1.2.189 E2056: Misplaced endif directive (C++)

The compiler encountered an `#endif` directive without any matching `#if`, `#ifdef`, or `#ifndef` directive.

3.1.2.190 E2059: Unknown language, must be C or C++ (C++)

In the C++ construction

```
extern "name" type func( /*...*/ );
```

the given "name" must be "C" or "C++" (use the quotes); other language names are not recognized.

You can declare an external Pascal function without the compiler's renaming like this:

```
extern "C" int pascal func( /*...*/ );
```

To declare a (possibly overloaded) C++ function as Pascal and allow the usual compiler renaming (to allow overloading), you can do this:

```
extern int pascal func( /*...*/ );
```

3.1.2.191 E2060: Illegal use of floating point (C++)

Floating-point operands are not allowed in these operators

- shift (SHL, SHR)
- bitwise Boolean (AND, OR, XOR, NOT)
- conditional (? :)
- indirection (*)
- certain others

The compiler found a floating-point operand with one of these prohibited operators.

3.1.2.192 E2061: Friends must be functions or classes (C++)

A friend of a C++ class must be a function or another class.

3.1.2.193 E2062: Invalid indirection (C++)

The indirection operator (*) requires a pointer as the operand.

Example

```
int main (void)
{
  int p;
  *p = 10;     /* ERROR: Invalid Indirection */
  return 0;
}
```

3.1.2.194 E2063: Illegal initialization (C++)

Initializations must be one of the following:

- constant expressions
- the address of a global extern or static variable plus or minus a constant

3.1.2.195 E2064: Cannot initialize 'type1' with 'type2' (C++)

You are attempting to initialize an object of type 'type1' with a value of type 'type2' which is not allowed.

The rules for initialization are essentially the same as for assignment.

3.1.2.196 E2068: 'identifier' is not a non-static data member and can't be initialized here (C++)

Only data members can be initialized in the initializers of a constructor.

This message means that the list includes a static member or function member.

Static members must be initialized outside of the class, for example:

```
class A { static int i; };
int A::i = -1;
```

3.1.2.197 E2069: Illegal use of member pointer (C++)

Pointers to class members can only be passed as arguments to functions, or used with the following operators:

- assignment operators
- comparison operators
- `.*`
- `–>*`
- `?:` conditional (ternary) operator
- && logical AND (see page 531) operator
- || logical OR (see page 559) operator

The compiler has encountered a member pointer being used with a different operator.

In order to call a member function pointer, one must supply an instance of the class for it to call upon.

For example:

```
class A {
public:
   myex();
};
typedef int (A::*Amfptr)();
myex()
{
   Amfptr mmyex = &A::myex;
   return (*mmyex)();  //error
}
```

This will compile:

```
class A {
public:
   myex();
};
typedef int (A::*Amfptr)();
foo()
{
   A a;
   Amfptr mmyex = &A::myex;
   return (a.*mmyex)();
}
```

3.1.2.198 E2071: operator new must have an initial parameter of type size_t (C++)

*E2071 Operator new[] must have an initial parameter of type size_t*Compiler error

Operator new can be declared with an arbitrary number of parameters.

It must always have at least one, the amount of space to allocate.

3.1.2.199 E2072: Operator new[] must return an object of type void (C++)

This C++ overloaded operator new was declared in some other way.

3.1.2.200 E2075: Incorrect 'type' option: option (C++)

An error has occurred in either the configuration file or a command-line option. The compiler may not have recognized the configuration file parameter as legal; check for a preceding hyphen (-), or the compiler may not have recognized the command-line parameter as legal.

This error can also occur if you use a `#pragma` option in your code with an invalid option.

3.1.2.201 E2076: Overloadable operator expected (C++)

Almost all C++ operators can be overloaded.

These are the only ones that can't be overloaded:

- the field-selection dot (`.`)
- dot-star (`.*`)
- double colon (`::`)
- conditional expression (`?:`)

The preprocessor operators (# and ##) are not C or C++ language operators and thus can't be overloaded.

Other non-operator punctuation, such as semicolon (;), can't be overloaded.

3.1.2.202 E2080: 'function' must be declared with one parameter (C++)

This C++ operator function was incorrectly declared with more than one parameter.

3.1.2.203 E2077: 'operator' must be declared with one or no parameters (C++)

When operator ++ or operator -- is declared as a member function, it must be declared to take either:

- No parameters (for the prefix version of the operator), or
- One parameter of type int (for the postfix version)

3.1.2.204 E2079: 'function' must be declared with no parameters (C++)

This C++ operator function was incorrectly declared with parameters.

3.1.2.205 E2078: 'operator' must be declared with one or two parameters (C++)

When operator ++ or operator -- is declared as a non-member function, it must be declared to take either:

- one parameter (for the prefix version of the operator), or
- two parameters (for the postfix version)

3.1.2.206 E2081: 'function' must be declared with two parameters (C++)

This C++ operator function was incorrectly declared with other than two parameters.

3.1.2.207 E2082: 'identifier' must be a member function or have a parameter of class type (C++)

Most C++ operator functions must have an implicit or explicit parameter of class type.

This operator function was declared outside a class and does not have an explicit parameter of class type.

3.1.2.208 E2083: Last parameter of 'operator' must have type 'int' (C++)

When a postfix operator ++ or operator -- is overloaded, the last parameter must be declared with the type int.

3.1.2.209 E2084: Parameter names are used only with a function body (C++)

When declaring a function (not defining it with a function body), you must use either empty parentheses or a function prototype.

A list of parameter names only is not allowed.

Example declarations

```
int func();             /* declaration without prototype -- OK */
int func(int, int);     /* declaration with prototype -- OK */
int func(int i, int j); /* parameter names in prototype -- OK */
int func(i, j);         /* parameter names only -- ILLEGAL */
```

3.1.2.210 E2085: Invalid pointer addition (C++)

Your source file attempted to add two pointers together.

3.1.2.211 E2086: Illegal pointer subtraction (C++)

This is caused by attempting to subtract a pointer from a non-pointer.

3.1.2.212 E2087: Illegal use of pointer (C++)

Pointers can only be used with these operators:

- addition(+)
- subtraction(-)
- assignment(=)
- comparison(==)
- indirection(*)
- arrow(->)

Your source file used a pointer with some other operator.

Example

```
int main (void)
{
  char *p;
  p /= 7;     /* ERROR: Illegal Use of Pointer */
  return 0;
}
```

3.1.2.213 E2088: Bad syntax for pure function definition (C++)

Pure virtual functions are specified by appending "= 0" to the declaration, like this:

```
class A { virtual void f () = 0;}
class B : public A { void f () {}; }
```

You wrote something similar, but it was not correct.

3.1.2.214 E2089: Identifier 'identifier' cannot have a type qualifier (C++)

A C++ qualifier class::identifier can't be applied here.

A qualifier is not allowed on the following:

- typedef names
- function declarations (except definitions at the file level)
- on local variables or parameters of functions
- on a class member--except to use its own class as a qualifier (redundant but legal).

3.1.2.215 E2090: Qualifier 'identifier' is not a class or namespace name (C++)

The C++ qualifier in the construction qual::identifier is not the name of a struct or class.

3.1.2.216 E2092: Storage class 'storage class' is not allowed here (C++)

The given storage class is not allowed here.

Probably two storage classes were specified, and only one can be given.

3.1.2.217 E2096: Illegal structure operation (C++)

Structures can only be used with dot (.), address-of (&) or assignment (=) operators, or be passed to or from a function as parameters.

The compiler encountered a structure being used with some other operator.

3.1.2.218 E2104: Invalid use of template keyword (C++)

You can only use a template class name without specifying its actual arguments inside a template definition.

Using a template class name without specifying its actual arguments outside a template definition is illegal.

3.1.2.219 E2108: Improper use of typedef 'identifier' (C++)

Your source file used a typedef symbol where a variable should appear in an expression.

Check for the declaration of the symbol and possible misspellings.

3.1.2.220 E2109: Not an allowed type (C++)

Your source file declared some sort of forbidden type; for example, a function returning a function or array.

3.1.2.221 E2110: Incompatible type conversion (C++)

The cast requested can't be done.

3.1.2.222 E2113: Virtual function 'function1' conflicts with base class 'base' (C++)

A virtual function has the same argument types as one in a base class, but differs in one or more of the following:

- Return type
- Calling convention
- Exception specification (throw list)

3.1.2.223 E2114: Multiple base classes require explicit class names (C++)

In a C++ class constructor, if there is more than one immediate base class, each base class constructor call in the constructor header must include the base class name.

3.1.2.224 E2115: Bit field too large (C++)

This error occurs when you supply a bit field with more than 16 bits.

3.1.2.225 E2116: Bit fields must contain at least one bit (C++)

You can't declare a named bit field to have 0 (or less than 0) bits.

You can declare an unnamed bit field to have 0 bits.

This is a convention used to force alignment of the following bit field to a byte boundary (or to a word boundary.

3.1.2.226 W8005: Bit fields must be signed or unsigned int (C++)

In ANSI C, bit fields may only be signed or unsigned int (not char or long, for example).

3.1.2.227 E2119: User break (C++)

You typed a Ctrl+Break while compiling in the IDE.

(This is not an error, just a confirmation.)

3.1.2.228 E2111: Type 'typename' may not be defined here (C++)

Class and enumeration types may not be defined in a function return type, a function argument type, a conversion operator type, or the type specified in a cast.

You must define the given type before using it in one of these contexts.

`Note:`This error message is often the result of a missing semicolon (`;`) for a class declaration. You might want to verify that all the class declarations preceding the line on which the error occurred end with a semicolon.

3.1.2.229 E2121: Function call missing) (C++)

The function call argument list had some sort of syntax error, such as a missing or mismatched right parenthesis.

3.1.2.230 E2123: Class 'class' may not contain pure functions (C++)

The class being declared cannot be abstract, and therefore it cannot contain any pure functions.

3.1.2.231 E2126: Case bypasses initialization of a local variable (C++)

In C++ it is illegal to bypass the initialization of a local variable.

This error indicates a case label that can transfer control past this local variable.

3.1.2.232 E2127: Case statement missing : (C++)

A case statement must have a constant expression followed by a colon.

The expression in the case statement either was missing a colon or had an extra symbol before the colon.

3.1.2.233 E2128: Case outside of switch (C++)

The compiler encountered a case statement outside a switch statement.

This is often caused by mismatched braces.

3.1.2.234 E2129: Character constant too long (or empty) (C++)

Character constants can only be one or two characters long.

3.1.2.235 E2133: Unable to execute command 'command' (C++)

The linker or assembler cannot be found, or possibly the disk is bad.

3.1.2.236 E2134: Compound statement missing closing brace (C++)

The compiler reached the end of the source file and found no closing brace.

This is most commonly caused by mismatched braces.

3.1.2.237 E2137: Destructor for 'class' required in conditional expression (C++)

If the compiler must create a temporary local variable in a conditional expression, it has no good place to call the destructor because the variable might or might not have been initialized.

The temporary can be explicitly created, as with classname(val, val), or implicitly created by some other code.

You should recast your code to eliminate this temporary value.

3.1.2.238 E2135: Constructor/Destructor cannot be declared 'const' or 'volatile' (C++)

A constructor or destructor has been declared as `const` or `volatile`.

This is not allowed.

3.1.2.239 E2138: Conflicting type modifiers (C++)

This occurs when a declaration is given that includes more than one addressing modifier on a pointer or more than one language modifier for a function.

Only one language modifier (for example, `__cdecl`, `__pascal`, or `__fastcall`) can be given for a function.

3.1.2.240 E2136: Constructor cannot have a return type specification (C++)

C++ constructors have an implicit return type used by the compiler, but you can't declare a return type or return a value.

3.1.2.241 E2038: Cannot declare or define 'identifier' here: wrong namespace (C++)

You tried to declare a template in an illegal place or a namespace member outside of its namespace.

3.1.2.242 E2154: Cannot define 'identifier' using a namespace alias (C++)

You cannot use a namespace alias to define a namespace member outside of its namespace.

3.1.2.243 E2421: Cannot use local type 'identifier' as template argument (C++)

A local type was used in an actual template type argument, which is illegal.

3.1.2.244 E2035: Conversions of class to itself or base class not allowed (C++)

You tried to define a conversion operator to the same class or a base class.

3.1.2.245 E2139: Declaration missing ; (C++)

Your source file contained a struct or union field declaration that was not followed by a semicolon.

Check previous lines for a missing semicolon.

3.1.2.246 E2140: Declaration is not allowed here (C++)

Declarations can't be used as the control statement for while, for, do, if, or switch statements.

3.1.2.247 E2141: Declaration syntax error (C++)

Your source file contained a declaration that was missing a symbol or had an extra symbol added to it.

Check for a missing semicolon or parenthesis on that line or on previous lines.

3.1.2.248 E2142: Base class 'class' contains dynamically dispatchable functions (C++)

This error occurs when a class containing a DDVT function attempts to inherit DDVT functions from multiple parent classes.

Currently, dynamically dispatched virtual tables do not support the use of multiple inheritance.

3.1.2.249 E2143: Matching base class function 'function' has different dispatch number (C++)

If a DDVT function is declared in a derived class, the matching base class function must have the same dispatch number as the derived function.

3.1.2.250 E2144: Matching base class function 'function' is not dynamic (C++)

If a DDVT function is declared in a derived class, the matching base class function must also be dynamic.

3.1.2.251 E2145: Functions 'function1' and 'function2' both use the same dispatch number (C++)

This error indicates a dynamically dispatched virtual table (DDVT) problem.

3.1.2.252 E2146: Need an identifier to declare (C++)

In this context, an identifier was expected to complete the declaration.

This might be a typedef with no name, or an extra semicolon at file level.

In C++, it might be a class name improperly used as another kind of identifier.

3.1.2.253 E2147: 'identifier' cannot start a parameter declaration (C++)

An undefined 'identifier' was found at the start of an argument in a function declarator.

Often the type name is misspelled or the type declaration is missing. This is usually caused by not including the appropriate header file.

3.1.2.254 E2150: Type mismatch in default argument value (C++)

The default parameter value given could not be converted to the type of the parameter.

The message "Type mismatch in default argument value" is used when the parameter was not given a name.

When compiling C++ programs, this message is always preceded by another message that explains the exact reason for the type mismatch.

That other message is most often "Cannot convert 'type1' to 'type2'" but the mismatch could be due to another reason.

3.1.2.255 E2152: Default expression may not use local variables (C++)

A default argument expression is not allowed to use any local variables or other parameters.

3.1.2.256 E2153: Define directive needs an identifier (C++)

The first non-whitespace character after a `#define` must be an identifier.

The compiler found some other character.

3.1.2.257 E2155: Too many default cases (C++)

The compiler encountered more than one default statement in a single switch.

3.1.2.258 E2156: Default outside of switch (C++)

The compiler encountered a default statement outside a switch statement.

This is most commonly caused by mismatched braces.

3.1.2.259 E2158: Operand of 'delete' must be non-const pointer (C++)

It is illegal to delete a variable that is not a pointer. It is also illegal to delete a pointer to a constant.

For example:

```
const int x=10;
   const int * a = &x;
   int * const b = new int;
   int &c = *b;
   delete a;   //illegal - deleting pointer to constant
   delete b;   //legal
   delete c;   //illegal - operand not of pointer type
               //should use 'delete&c' instead
```

3.1.2.260 E2159: Trying to derive a far class from the huge base 'base' (C++)

This error is no longer generated by the compiler.

3.1.2.261 E2160: Trying to derive a far class from the near base 'base' (C++)

If a class is declared (or defaults to) near, all derived classes must also be near.

3.1.2.262 E2161: Trying to derive a huge class from the far base 'base' (C++)

This error is no longer generated by the compiler.

3.1.2.263 E2162: Trying to derive a huge class from the near base 'base' (C++)

This error is no longer generated by the compiler.

3.1.2.264 E2163: Trying to derive a near class from the far base 'base' (C++)

If a class is declared (or defaults to) far, all derived classes must also be far.

3.1.2.265 E2164: Trying to derive a near class from the huge base 'base' (C++)

This error is no longer generated by the compiler.

3.1.2.266 E2165: Destructor cannot have a return type specification (C++)

C++ destructors never return a value, and you can't declare a return type or return a value.

3.1.2.267 E2166: Destructor for 'class' is not accessible (C++)

The destructor for this C++ class is protected or private, and can't be accessed here to destroy the class.

If a class destructor is private, the class can't be destroyed, and thus can never be used. This is probably an error.

A protected destructor can be accessed only from derived classes.

This is a useful way to ensure that no instance of a base class is ever created, but only classes derived from it.

3.1.2.268 E2167: 'function' was previously declared with the language 'language' (C++)

Only one language modifier (cdecl pascal) can be given for a function.

This function has been declared with different language modifiers in two locations.

3.1.2.269 E2168: Division by zero (C++)

Your source file contains a divide or remainder in a constant expression with a zero divisor.

3.1.2.270 E2169: 'identifier' specifies multiple or duplicate access (C++)

A base class can be declared public or private, but not both.

This access specifier can appear no more than once for a base class.

3.1.2.271 E2170: Base class 'class' is included more than once (C++)

A C++ class can be derived from any number of base classes, but can be directly derived from a given class only once.

3.1.2.272 E2171: Body has already been defined for function 'function' (C++)

A function with this name and type was previously supplied a function body.

A function body can only be supplied once.

One cause of this error is not declaring a default constructor which you implement. For example:

```
class A {
public:
   virtual myex();
};
A::A() {} // error
```

Having not seen you declare the default constructor in the class declaration, the compiler has had to generate one, thus giving the error message when it sees one. this is a correct example:

```
class A {
public:
   A();
   virtual myex();
};
A::A() {}
```

3.1.2.273 E2172: Duplicate case (C++)

Each case of a switch statement must have a unique constant expression value.

3.1.2.274 E2175: Too many storage classes in declaration (C++)

A declaration can never have more than one storage class, either Auto, Register, Static, or Extern.

3.1.2.275 E2176: Too many types in declaration (C++)

A declaration can never have more than one basic type. Examples of basic types are:

- char
- class
- int
- float
- double
- struct
- union
- enum
- typedef name

3.1.2.276 E2179: virtual specified more than once (C++)

The C++ reserved word "virtual" can appear only once in one member function declaration.

3.1.2.277 E2007: Dispid only allowed in __automated sections (C++)

The definition of dispids is only permitted in __automated sections.

Example

```
struct__declspec(delphiclass) clxclass
{
int __fastcall foo1(void) __dispid(42);// Error
__automated:
int __fastcall foo2(void) __dispid(43);// OK
};
```

3.1.2.278 Divide error (C++)

You tried to divide an integer by zero, which is illegal.

3.1.2.279 E2182: Illegal parameter to __emit__ (C++)

There are some restrictions on inserting literal values directly into your code with the __emit__ function.

For example, you cannot give a local variable as a parameter to __emit__.

3.1.2.280 E2183: File must contain at least one external declaration (C++)

This compilation unit was logically empty, containing no external declarations.

ANSI C and C++ require that something be declared in the compilation unit.

3.1.2.281 E2184: Enum syntax error (C++)

An `enum` declaration did not contain a properly formed list of identifiers.

3.1.2.282 E2185: The value for 'identifier' is not within the range of 'type-name' (C++)

You have attempted to assign a value that is out of the range of the specified type.

3.1.2.283 E2186: Unexpected end of file in comment started on line 'number' (C++)

The source file ended in the middle of a comment.

This is normally caused by a missing close of comment (*/).

3.1.2.284 E2187: Unexpected end of file in conditional started on line 'number' (C++)

The source file ended before the compiler (or MAKE) encountered `#endif`.

The `#endif` either was missing or misspelled.

Every `#if` statement needs a matching `#endif` statement.

3.1.2.285 E2188: Expression syntax (C++)

This is a catch-all error message when the compiler parses an expression and encounters a serious error.

Possible Causes

This is most commonly caused by one of the following:

- two consecutive operators
- mismatched or missing parentheses
- a missing semicolon on the previous statement.

Solutions

If the line where the error occurred looks syntactically correct, look at the line directly above for errors.

Try moving the line with the error to a different location in the file and recompiling.

If the error still occurs at the moved statement, the syntax error is occurring somewhere in that statement.

If the error occurred in another statement, the syntax error is probably in the surrounding code.

3.1.2.286 E2190: Unexpected closing brace (C++)

An extra right brace was encountered where none was expected. Check for a missing closing brace.

Useful Tip:

The IDE has a mechanism for finding a matching curly brace. If you put the cursor on the '{' or '}' character, hold down Ctrl, hit 'Q' and then '{' or '}', it will position the cursor on the matching brace.

3.1.2.287 E2189: extern variable cannot be initialized (C++)

The storage class extern applied to a variable means that the variable is being declared but not defined here--no storage is being allocated for it.

Therefore, you can't initialize the variable as part of the declaration.

3.1.2.288 E2344: Earlier declaration of 'identifier' (C++)

This error message only shows up after the messages "Multiple declaration for 'identifier'" and "Type mismatch in redeclaration of 'identifier'". It tells you where the previous definition of the identifier in question was found by the compiler, so you don't have to search for it.

3.1.2.289 E2192: Too few parameters in call (C++)

This error message occurs when a call to a function with a prototype (via a function pointer) had too few arguments. Prototypes require that all parameters be given. Make certain that your call to a function has the same parameters as the function prototype.

3.1.2.290 E2193: Too few parameters in call to 'function' (C++)

A call to the named function (declared using a prototype) has too few arguments.

Make certain that the parameters in the call to the function match the parameters of the function prototype.

3.1.2.291 E2194: Could not find file 'filename' (C++)

The compiler is unable to find the file supplied on the command line.

3.1.2.292 E2197: File name too long (C++)

The file name given in an `#include` directive was too long for the compiler to process.

File names in DOS must be no more than 79 characters long.

3.1.2.293 E2195: Cannot evaluate function call (C++)

The error message is issued if someone tries to explicitly construct an object or call a virtual function.

In integrated debugger expression evaluation, calls to certain functions (including implicit conversion functions, constructors, destructors, overloaded operators, and inline functions) are not supported.

3.1.2.294 E2198: Not a valid expression format type (C++)

Invalid format specifier following expression in the debug evaluate or watch window. A valid format specifier is an optional repeat value followed by a format character (c, d, f[n], h, x, m, p, r, or s).

3.1.2.295 E2200: Functions may not be part of a struct or union (C++)

This C struct or union field was declared to be of type function rather than pointer to function.

Functions as fields are allowed only in C++.

3.1.2.296 Floating point error: Divide by 0 OR Floating point error: Domain OR Floating point error: Overflow (C++)

These fatal errors result from a floating-point operation for which the result is not finite:

- Divide by 0 means the result is +INF or -INF exactly, such as 1.0/0.0.
- Domain means the result is NAN (not a number), like 0.0/0.0.
- Overflow means the result is +INF (infinity) or -INF with complete loss of precision, such as assigning 1e200*1e200 to a double.

3.1.2.297 Floating point error: Stack fault (C++)

The floating-point stack has been overrun. This error may be due to assembly code using too many registers or due to a misdeclaration of a floating-point function.

The program prints the error message and calls abort and _exit.

These floating-point errors can be avoided by masking the exception so that it doesn't occur, or by catching the exception with signal.

3.1.2.298 Floating point error: Partial loss of precision OR Floating point error: Underflow (C++)

These exceptions are masked by default, because underflows are converted to zero and losses of precision are ignored.

3.1.2.299 E2201: Too much global data defined in file (C++)

The sum of the global data declarations exceeds 64K bytes. This includes any data stored in the DGROUP (all global variables, literal strings, and static locals).

Solutions

Check the declarations for any array that might be too large. You can also remove variables from the DGROUP.

Here's how:

- Declare the variables as automatic. This uses stack space.
- Dynamically allocate memory from the heap using calloc, malloc, or farmalloc for the variables. This requires the use of pointers.

Literal strings are also put in the DGROUP. Get the file farstr.zip from our BBS to extract literal strings into their own segment.

3.1.2.300 E2203: Goto bypasses initialization of a local variable (C++)

In C++, it is illegal to bypass the initialization of a local variable.

This error indicates a goto statement that can transfer control past this local variable.

3.1.2.301 E2204: Group overflowed maximum size: 'name' (C++)

The total size of the segments in a group (for example, DGROUP) exceeded 64K.

3.1.2.302 E2206: Illegal character 'character' (0x'value') (C++)

The compiler encountered some invalid character in the input file.

The hexadecimal value of the offending character is printed.

This can also be caused by extra parameters passed to a function macro.

3.1.2.303 E2207: Implicit conversion of 'type1' to 'type2' not allowed (C++)

When a member function of a class is called using a pointer to a derived class, the pointer value must be implicitly converted to point to the appropriate base class.

In this case, such an implicit conversion is illegal.

3.1.2.304 E2208: Cannot access an inactive scope (C++)

You have tried to evaluate or inspect a variable local to a function that is currently not active. (This is an integrated debugger expression evaluation message.)

3.1.2.305 E2209: Unable to open include file 'filename' (C++)

The compiler could not find the named file.

Possible Causes

- The named file does not exist.
- An `#include` file included itself.
- You do not have FILES set in CONFIG.SYS on your root directory.

Solutions

- Verify that the named file exists.
- Set FILES = 20 in CONFIG.SYS.

3.1.2.306 E2210: Reference member 'member' is not initialized (C++)

References must always be initialized, in the constructor for the class.

A class member of reference type must have an initializer provided in all constructors for that class.

This means you can't depend on the compiler to generate constructors for such a class, because it has no way of knowing how to initialize the references.

3.1.2.307 E2212: Function defined inline after use as extern (C++)

Functions can't become inline after they have already been used.

Either move the inline definition forward in the file or delete it entirely.

The compiler encountered something like:

```
myex();
twoex() { myex(); }
inline myex() { return 2; } // error
```

and already used the function as an extern before it saw that it was specified as inline. This would be correct:

```
myex();
inline myex() { return 2; }
twoex() { myex(); }
```

or better:

```
inline myex();
inline myex() { return 2; }
twoex() { myex(); }
```

3.1.2.308 E2211: Inline assembly not allowed in inline and template functions (C++)

The compiler can't handle inline assembly statements in a C++ inline or template function.

You could eliminate the inline assembly code or, in the case of an inline function, make this a macro, and remove the inline storage class.

3.1.2.309 F1001: Internal code generator error (C++)

An error has occurred in the internal logic of the code generator. Contact CodeGear technical support.

3.1.2.310 E2413: Invalid template declaration (C++)

After the declarator of a template member, either a semicolon, an initialization, or a body was expected, but some other, illegal token was found. This message appears when a template member is declared outside of the template, but the syntax was wrong.

3.1.2.311 E2070: Invalid use of namespace 'identifier' (C++)

A namespace identifier was used in an illegal way, for example, in an expression.

3.1.2.312 E2214: Cannot have a 'non-inline function/static data' in a local class (C++)

All members of classes declared local to a function must be entirely defined in the class definition.

This means that local classes cannot contain any static data members, and all of their member functions must have bodies defined within the class definition.

3.1.2.313 E2215: Linkage specification not allowed (C++)

Linkage specifications such as extern "C" are only allowed at the file level.

Move this function declaration out to the file level.

3.1.2.314 E2216: Unable to create turboc.$ln (C++)

The compiler cannot create the temporary file TURBOC.$LN because it cannot access the disk or the disk is full.

3.1.2.315 E2218: Templates can only be declared at namespace or class scope (C++)

Templates cannot be declared inside classes or functions. They are only allowed in the global scope, or file level.

For example:

```
void func()
{
  template <class T> myClass {  // Error
    T i;
  };
}
```

3.1.2.316 E2217: Local data exceeds segment size limit (C++)

The local variables in the current function take up more than 64K.

3.1.2.317 E2219: Wrong number of arguments in call of macro 'macro' (C++)

Your source file called the named macro with an incorrect number of arguments.

3.1.2.318 E2220: Invalid macro argument separator (C++)

In a macro definition, arguments must be separated by commas.

The compiler encountered some other character after an argument name.

This is correct:

```
#define tri_add(a, b, c)  ((a) + (b) + (c))
```

This is incorrect:

```
#define tri_add(a  b. c)  ((a) + (b) + (c))
```

3.1.2.319 E2221: Macro argument syntax error (C++)

An argument in a macro definition must be an identifier.

The compiler encountered some non-identifier character where an argument was expected.

3.1.2.320 E2222: Macro expansion too long (C++)

A macro can't expand to more than 4,096 characters.

3.1.2.321 E2223: Too many decimal points (C++)

The compiler encountered a floating-point constant with more than one decimal point.

3.1.2.322 E2224: Too many exponents (C++)

The compiler encountered more than one exponent in a floating-point constant.

3.1.2.323 E2225: Too many initializers (C++)

The compiler encountered more initializers than were allowed by the declaration being initialized.

3.1.2.324 E2226: Extra parameter in call (C++)

A call to a function, via a pointer defined with a prototype, had too many arguments.

3.1.2.325 E2227: Extra parameter in call to function (C++)

A call to the named function (which was defined with a prototype) had too many arguments given in the call.

3.1.2.326 E2228: Too many error or warning messages (C++)

There were more errors or warnings than allowed.

3.1.2.327 E2233: Cannot initialize a class member here (C++)

Individual members of structs, unions, and C++ classes can't have initializers.

A struct or union can be initialized as a whole using initializers inside braces.

A C++ class can only be initialized by the use of a constructor.

3.1.2.328 E2232: Constant/Reference member 'member' in class without constructors (C++)

A class that contains constant or reference members (or both) must have at least one user-defined constructor.

Otherwise, there would be no way to ever initialize such members.

3.1.2.329 E2229: Member 'member' has the same name as its class (C++)

A static data member, enumerator, member of an anonymous union, or nested type cannot have the same name as its class.

Only a member function or a non-static member can have a name that is identical to its class.

3.1.2.330 E2234: Memory reference expected (C++)

The built-in assembler requires a memory reference.

You probably forgot to put square brackets around an index register operand.

3.1.2.331 E2231: Member 'member' cannot be used without an object (C++)

This means that you have written class::member where 'member' is an ordinary (non-static) member, and there is no class to associate with that member.

For example, it is legal to write this:

```
obj.class::member
```

but not to write this:

```
class::member
```

3.1.2.332 E2235: Member function must be called or its address taken (C++)

A reference to a member function must be called, or its address must be taken with & operator.

In this case, a member function has been used in an illegal context.

For example:

```
class A
{
   typedef int (A::* infptr)(void);
public:
   A();
   int myex(void);
   int three;
} a;
A::A()
{
   infptr one = myex;       //illegal - call myex or take address?
   infptr two = &A::myex;   //correct
   three = (a.*one)() + (a.*two)();
}
```

3.1.2.333 O2237: DPMI programs must use the large memory model (C++)

The compiler no longer issues this error.

3.1.2.334 E2238: Multiple declaration for 'identifier' (C++)

This identifier was improperly declared more than once.

This might be caused by conflicting declarations such as:

- int a; double a;
- a function declared two different ways, or
- a label repeated in the same function, or
- some declaration repeated other than an extern function or a simple variable

This can also happen by inadvertently including the same header file twice. For example, given:

```
//a.h
struct A { int a; };
//b.h
#include "a.h"
//myprog.cpp
#include "a.h"
#include "b.h"
```

myprog.cpp will get two declarations for the struct A. To protect against this, one would write the a.h header file as:

```
//a.h
#ifndef __A_H
#define __A_H
struct A { int a; };
#endif
```

This will allow one to safely include a.h several times in the same source code file.

3.1.2.335 E2239: 'identifier' must be a member function (C++)

Most C++ operator functions can be members of classes or ordinary non-member functions, but these are required to be members of classes:

- operator =
- operator ->
- operator ( )
- type conversions

This operator function is not a member function but should be.

3.1.2.336 E2240: Conversion of near pointer not allowed (C++)

A near pointer cannot be converted to a far pointer in the expression evaluation box when a program is not currently running. This is because the conversion needs the current value of DS in the user program, which doesn't exist.

3.1.2.337 E2243: Array allocated using 'new' may not have an initializer (C++)

When initializing a vector (array) of classes, you must use the constructor that has no arguments.

This is called the default constructor, which means that you can't supply constructor arguments when initializing such a vector.

3.1.2.338 E2244: 'new' and 'delete' not supported (C++)

The integrated debugger does not support the evaluation of the new and delete operators.

3.1.2.339 E2245: Cannot allocate a reference (C++)

You have attempted to create a reference using the new operator.

This is illegal, because references are not objects and can't be created through new.

3.1.2.340 E2309: Inline assembly not allowed (C++)

Your source file contains inline assembly language statements and you are compiling it from within the integrated environment.

You must use the BCC command to compile this source file from the DOS command line.

3.1.2.341 E2250: No base class to initialize (C++)

This C++ class constructor is trying to implicitly call a base class constructor, but this class was declared with no base classes.

Check your declarations.

3.1.2.342 E2254: : expected after private/protected/private (C++)

When used to begin a private, protected, or public section of a C++ class, the reserved words "private," "protected," and "public" must be followed by a colon.

3.1.2.343 E2255: Use :: to take the address of a member function (C++)

If f is a member function of class c, you take its address with the syntax

```
&c::f
```

Note the use of the class type name (not the name of an object) and the :: separating the class name from the function name.

(Member function pointers are not true pointer types, and do not refer to any particular instance of a class.)

3.1.2.344 E2256: No : following the ? (C++)

The question mark (?) and colon (:) operators do not match in this expression.

The colon might have been omitted, or parentheses might be improperly nested or missing.

3.1.2.345 E2257: , expected (C++)

A comma was expected in a list of declarations, initializations, or parameters.

This problem is often caused by a missing syntax element earlier in the file or one of its included headers.

3.1.2.346 E2258: Declaration was expected (C++)

A declaration was expected here but not found.

This is usually caused by a missing delimiter such as a comma, semicolon, right parenthesis, or right brace.

3.1.2.347 E2259: Default value missing (C++)

When a C++ function declares a parameter with a default value, all of the following parameters must also have default values.

In this declaration, a parameter with a default value was followed by a parameter without a default value.

3.1.2.348 E2260: Default value missing following parameter 'parameter' (C++)

All parameters following the first parameter with a default value must also have defaults specified.

3.1.2.349 E2263: Exception handling not enabled (C++)

A 'try' block was found with the exception handling disabled.

3.1.2.350 E2264: Expression expected (C++)

An expression was expected here, but the current symbol can't begin an expression.

This message might occur where the controlling expression of an if or while clause is expected or where a variable is being initialized.

This message is often due to a symbol that is missing or has been added.

3.1.2.351 E2266: No file names given (C++)

The command line contained no file names. You must specify a source file name.

3.1.2.352 E2265: No file name ending (C++)

The file name in an `#include` statement was missing the correct closing quote or angle bracket.

3.1.2.353 E2271: Goto statement missing label (C++)

The `goto` keyword must be followed by an identifier.

3.1.2.354 E2272: Identifier expected (C++)

An identifier was expected here, but not found.

In C, an identifier is expected in the following situations:

- in a list of parameters in an old-style function header
- after the reserved words struct or union when the braces are not present, and

- as the name of a member in a structure or union (except for bit fields of width 0).

In C++, an identifier is also expected in these situations:

- in a list of base classes from which another class is derived, following a double colon (::), and
- after the reserved word "operator" when no operator symbol is present.

3.1.2.355 E2275: Opening brace expected (C++)

A left brace was expected at the start of a block or initialization.

3.1.2.356 E2276: (expected (C++)

A left parenthesis was expected before a parameter list.

3.1.2.357 E2274: < expected (C++)

The keyword `template` was not followed by <.

Every template declaration must include the template formal parameters enclosed within < >, immediately following the template keyword.

3.1.2.358 E2277: Lvalue required (C++)

The left side of an assignment operator must be an addressable expression.

Addressable expressions include the following:

- numeric or pointer variables
- structure field references or indirection through a pointer
- a subscripted array element

3.1.2.359 E2278: Multiple base classes not supported for Delphi classes (C++)

Delphi style classes cannot have multiple base classes.

Example

```
struct__declspec(delphiclass) base1  {};
struct__declspec(delphiclass) base2  {};
structderived : base1, base2         {}; // Error
```

3.1.2.360 E2280: Member identifier expected (C++)

The name of a structure or C++ class member was expected here, but not found. The right side of a dot (.) or arrow (->) operator must be the name of a member in the structure or class on the left of the operator.

3.1.2.361 E2279: Cannot find default constructor to initialize member 'identifier' (C++)

When the following occurs

1.A C++ class 'class1' contains a member of class 'class2,'

and

2.You want to construct an object of type 'class1' (but not from another object of type 'class1'). There must be a constructor class2::class2() so that the member can be constructed.

This constructor without parameters is called the default constructor.

The compiler will supply a default constructor automatically unless you have defined any constructor for class 'class2'.

In that case, the compiler will not supply the default constructor automatically (you must supply one.

3.1.2.362 E2310: Only member functions may be 'const' or 'volatile' (C++)

Something other than a class member function has been declared `const` or `volatile`.

3.1.2.363 E2311: Non-virtual function 'function' declared pure (C++)

Only virtual functions can be declared pure, because derived classes must be able to override them.

3.1.2.364 E2283: Use . or -> to call 'function' (C++)

You attempted to call a member function without providing an object. This is required to call a member function.

```
class X {
   member func() {}
};
X x;
X*xp = new X;
X.memberfunc();
Xp-> memberfunc();
```

3.1.2.365 E2284: Use . or -> to call 'member', or & to take its address (C++)

A reference to a non-static class member without an object was encountered.

Such a member can't be used without an object, or its address must be taken with the & operator.

3.1.2.366 E2285: Could not find a match for 'argument(s)' (C++)

No C++ function could be found with parameters matching the supplied arguments. Check parameters passed to function or

overload function for parameters that are being passed.

3.1.2.367 E2286: Overloaded function resolution not supported (C++)

In integrated debugger expression evaluation, resolution of overloaded functions or operators is not supported, not even to take an address.

3.1.2.368 E2287: Parameter 'number' missing name (C++)

In a function definition header, this parameter consisted only of a type specifier 'number' with no parameter name.

This is not legal in C.

(It is allowed in C++, but there's no way to refer to the parameter in the function.)

3.1.2.369 E2288: Pointer to structure required on left side of -> or ->* (C++)

Nothing but a pointer is allowed on the left side of the arrow (->) in C or C++.

In C++ a -> operator is allowed.

3.1.2.370 E2290: 'code' missing] (C++)

This error is generated if any of the following occur:

- Your source file declared an array in which the array bounds were not terminated by a right bracket.
- The array specifier in an operator is missing a right bracket.
- The operator [ ] was declared as operator [.
- A right bracket is missing from a subscripting expression.

Add the bracket or fix the declaration.

Check for a missing or extra operator or mismatched parentheses.

3.1.2.371 E2291: brace expected (C++)

A right brace was expected at the end of a block or initialization.

3.1.2.372 E2292: Function should return a value (C++)

Your source file declared the current function to return some type other than `int` or `void`, but the compiler encountered a return with no value. This usually indicates some sort of error.

Functions declared as returning `int` are exempt because older versions of C did not support `void` function return types.

3.1.2.373 E2293:) expected (C++)

A right parenthesis was expected at the end of a parameter list.

3.1.2.374 E2294: Structure required on left side of . or .* (C++)

The left side of a dot (.) operator (or C++ dot-star operator, .*) must evaluate to a structure type. In this case it did not.

This error can occur when you create an instance of a class using empty parentheses, and then try to access a member of that 'object'.

3.1.2.375 E2312: 'constructor' is not an unambiguous base class of 'class' (C++)

A C++ class constructor is trying to call a base class constructor 'constructor.'

This error can also occur if you try to change the access rights of 'class::constructor.'

Check your declarations.

3.1.2.376 E2313: Constant expression required (C++)

Arrays must be declared with constant size.

This error is commonly caused by misspelling a `#define` constant.

3.1.2.377 E2296: Templates not supported (C++)

An error has occurred while using the command-line utility H2ASH. See the online file "tsm_util.txt" for further information about this utility.

3.1.2.378 E2314: Call of nonfunction (C++)

The name being called is not declared as a function.

This is commonly caused by incorrectly declaring the function or misspelling the function name.

3.1.2.379 E2321: Declaration does not specify a tag or an identifier (C++)

This declaration doesn't declare anything.

This may be a struct or union without a tag or a variable in the declaration. C++ requires that something be declared.

For example:

```
struct
{
int a
};
//no tag or identifier
```

3.1.2.380 E2297: 'this' can only be used within a member function (C++)

In C++, "this" is a reserved word that can be used only within class member functions.

3.1.2.381 E2316: 'identifier' is not a member of 'struct' (C++)

You are trying to reference 'identifier' as a member of 'struct', but it is not a member.

Check your declarations.

3.1.2.382 E2317: 'identifier' is not a parameter (C++)

In the parameter declaration section of an old-style function definition, 'identifier' is declared but not listed as a parameter. Either remove the declaration or add 'identifier' as a parameter.

3.1.2.383 E2319: 'identifier' is not a public base class of 'classtype' (C++)

The right operand of a .*, ->*, or ::operator was not a pointer to a member of a class that is either identical to (or an unambiguous accessible base class of) the left operand's class type.

3.1.2.384 E2320: Expression of scalar type expected (C++)

The !, ++, and -- operators require an expression of scalar type.

Only these types are allowed:

- char
- short
- int
- long
- enum
- float
- double
- long double
- pointer

3.1.2.385 E2302: No type information (C++)

The integrated debugger has no type information for this variable. Ensure that you've compiled the module with debug information. If it has, the module may have been compiled by another compiler or assembler.

3.1.2.386 E2303: Type name expected (C++)

One of these errors has occurred:

- In declaring a file-level variable or a struct field, neither a type name nor a storage class was given.
- In declaring a typedef, no type for the name was supplied.
- In declaring a destructor for a C++ class, the destructor name was not a type name (it must be the same name as its class).
- In supplying a C++ base class name, the name was not the name of a class.

3.1.2.387 E2304: 'Constant/Reference' variable 'variable' must be initialized (C++)

This C++ object is declared constant or as a reference, but is not initialized.

It must be initialized at the point of declaration.

3.1.2.388 E2305: Cannot find 'class::class' ('class'&) to copy a vector OR Cannot find 'class'::operator=('class'&) to copy a vector (C++)

When a C++ class 'class1' contains a vector (array) of class 'class2', and you want to construct an object of type 'class1' from another object of type 'class 1', you must use this constructor:

```
class2::class2(class2&)
```

so that the elements of the vector can be constructed.

The constructor, called a copy constructor, takes just one parameter (which is a reference to its class).

Usually, the compiler supplies a copy constructor automatically.

However, if you have defined a constructor for class 'class2' that has a parameter of type 'class2&' and has additional parameters with default values, the copy constructor can't exist and can't be created by the compiler.

This is because these two can't be distinguished:

```
class2::class2(class2&)
class2::class2(class2&, int = 1)
```

You must redefine this constructor so that not all parameters have default values.

You can then define a reference constructor or let the compiler create one.

Cannot find class::operator= ...

When a C++ class 'class1' contains a vector (array) of class 'class2', and you want to copy a class of type 'class1', you must use this assignment operator:

```
class2::class2(class2&)
```

so that the elements of the vector can be copied.

Usually, the compiler automatically supplies this operator.

However, if you have defined an operator= for class 'class2' that does not take a parameter of type 'class2&,' the compiler will not supply it automatically--you must supply one.

3.1.2.389 E2306: Virtual base classes not supported for Delphi classes (C++)

Delphi style classes cannot be derived virtually, not even from other Delphi style classes.

Example

```
struct __declspec(delphiclass) base  {};
struct derived : virtual base        {};    // Error
```

3.1.2.390 E2308: do statement must have while (C++)

Your source file contained a do statement that was missing the closing while keyword.

3.1.2.391 E2322: Incorrect number format (C++)

The compiler encountered a decimal point in a hexadecimal number.

3.1.2.392 E2324: Numeric constant too large (C++)

String and character escape sequences larger than hexadecimal or octal 77 can't be generated.

Two-byte character constants can be specified by using a second backslash. For example,

```
\\
```

represents a two-byte constant.

A numeric literal following an escape sequence should be broken up like this:

```
printf("\x0A" "12345");
```

This prints a carriage return followed by 12345.

3.1.2.393 E2282: Namespace name expected (C++)

The name of a namespace symbol was expected.

3.1.2.394 E2334: Namespace member 'identifier' declared outside its namespace (C++)

Namespace members must be declared inside their namespace. You can only use explicit qualification to define a namespace

member (for example, to give a body for a function declared in a namespace). The declaration itself must be inside the namespace.

3.1.2.395 E2325: Illegal octal digit (C++)

The compiler found an octal constant containing a non-octal digit (8 or 9).

3.1.2.396 E2329: Invalid combination of opcode and operands (C++)

The built-in assembler does not accept this combination of operands.

Possible causes

- There are too many or too few operands for this assembler opcode.
- The number of operands is correct, but their types or order do not match the opcode.

3.1.2.397 E2327: Operators may not have default argument values (C++)

It is illegal for overloaded operators to have default argument values.

3.1.2.398 E2330: Operator must be declared as function (C++)

An overloaded operator was declared with something other than function type.

For example:

```
class A
{
   A& operator +;   ..note missing parenthesis
};
```

In the example, the function operator '()' is missing, so the operator does not have function type and generates this error.

3.1.2.399 E2333: Class member 'member' declared outside its class (C++)

C++ class member functions can be declared only inside the class declaration.

Unlike nonmember functions, they can't be declared multiple times or at other locations.

3.1.2.400 E2335: Overloaded 'function name' ambiguous in this context (C++)

The only time an overloaded function name can be used or assigned without actually calling the function is when a variable or parameter of the correct function pointer type is initialized or assigned the address of the overload function.

In this case, an overloaded function name has been used in some other context, for example, the following code will generate this error:

```
class A{
   A(){myex;}           //calling the function
   void myex(int) {}    //or taking its address?
   void myex(float){}
};
```

3.1.2.401 E2339: Cannot overload 'main' (C++)

You cannot overload main.

3.1.2.402 E2336: Pointer to overloaded function 'function' doesn't match 'type' (C++)

A variable or parameter is assigned (or initialized with) the address of an overloaded function.

However, the type of the variable or parameter doesn't match any of the overloaded functions with the specified name.

3.1.2.403 E2337: Only one of a set of overloaded functions can be "C" (C++)

C++ functions are by default overloaded, and the compiler assigns a new name to each function.

If you wish to override the compiler's assigning a new name by declaring the function `extern` "C", you can do this for only one of a set of functions with the same name.

(Otherwise the linker would find more than one global function with the same name.)

3.1.2.404 E2338: Overlays only supported in medium, large, and huge memory models (C++)

The compiler no longer issues this error.

3.1.2.405 E2340: Type mismatch in parameter 'number' (C++)

The function called, via a function pointer, was declared with a prototype.

However, the given parameter number (counting left to right from 1) could not be converted to the declared parameter type.

When compiling C++ programs, this message is always preceded by another message that explains the exact reason for the type mismatch.

That other message is usually "Cannot convert 'type1' to 'type2'" but the mismatch might be due to many other reasons.

3.1.2.406 E2341: Type mismatch in parameter 'number' in call to 'function' (C++)

Your source file declared the named function with a prototype, and the given parameter number (counting left to right from 1) could not be converted to the declared parameter type.

When compiling C++ programs, this message is always preceded by another message that explains the exact reason for the type mismatch.

That other message is usually "Cannot convert 'type1' to 'type2'", but the mismatch might be due to many other reasons.

3.1.2.407 E2342: Type mismatch in parameter 'parameter' (C++)

Your source file declared the function called via a function pointer with a prototype.

However, the named parameter could not be converted to the declared parameter type.

When compiling C++ programs, this message is always preceded by another message that explains the exact reason for the type mismatch.

That other message is usually "Cannot convert 'type1' to 'type2'" but the mismatch might be due to many other reasons.

3.1.2.408 E2343: Type mismatch in parameter 'parameter' in call to 'function' (C++)

Your source file declared the named function with a prototype, and the named parameter could not be converted to the declared parameter type.

When compiling C++ programs, this message is always preceded by another message that explains the exact reason for the type mismatch.

That other message is usually "Cannot convert 'type1' to 'type2'" but the mismatch might be due to many other reasons.

3.1.2.409 E2345: Access can only be changed to public or protected (C++)

A C++ derived class can modify the access rights of a base class member, but only to public or protected.

A base class member can't be made private.

3.1.2.410 E2349: Nonportable pointer conversion (C++)

An implicit conversion between a pointer and an integral type is required, but the types are not the same size. You must use an explicit cast.

This conversion might not make any sense, so be sure this is what you want to do.

3.1.2.411 E2350: Cannot define a pointer or reference to a reference (C++)

It is illegal to have a pointer to a reference or a reference to a reference.

3.1.2.412 E2352: Cannot create instance of abstract class 'class' (C++)

Abstract classes (those with pure virtual functions) can't be used directly, only derived from.

When you derive an abstract base class, with the intention to instantiate instances of this derived class, you must override each of the pure virtual functions of the base class exactly as they are declared.

For example:

```
class A {
public:
   virtual myex( int ) = 0;
   virtual twoex( const int ) const = 0;
};
class B : public A {
public:
   myex( int );
   twoex( const int );
};
B b;   // error
```

The error occurs because we have not overridden the virtual function in which twoex can act on const objects of the class. We have created a new one which acts on non-const objects. This would compile:

```
class A {
public:
   virtual myex( int ) = 0;
   virtual twoex( const int ) const = 0;
};
class B : public A {
public:
   myex( int );
   twoex( const int ) const;
};
B b;   // ok
```

3.1.2.413 E2354: Two operands must evaluate to the same type (C++)

The types of the expressions on both sides of the colon in the conditional expression operator (?:) must be the same, except for the usual conversions.

These are some examples of usual conversions

- `char` to `int`
- `float` to `double`
- void* to a particular pointer

In this expression, the two sides evaluate to different types that are not automatically converted.

This might be an error or you might merely need to cast one side to the type of the other.

When compiling C++ programs, this message is always preceded by another message that explains the exact reason for the type mismatch.

That other message is usually "Cannot convert 'type1' to 'type2'" but the mismatch might be due to many other reasons.

3.1.2.414 E2355: Recursive template function: 'x' instantiated 'y' (C++)

The compiler has detected a recursive template function instance. For example:

```
template<class T> void f(T x)
{
   f((T*)0);   // recursive template function!
}
void main()
{
   f(0);
}
```

The compiler issue one message for each nesting of the recursive instantiation, so it is usually obvious where the recursion has occurred. To fix a recursive template, either change the dependencies or provide a specialized version that will stop the recursion. For example, adding the following function definition to the above program will remove the endless recursion:

```
void f(int **)
{
}
```

3.1.2.415 E2356: Type mismatch in redeclaration of 'identifier' (C++)

Your source file redeclared a variable with a different type than was originally declared for the variable.

Possible Causes

This can occur if a function is called and subsequently declared to return something other than an integer.

Solutions

If this has happened, you must declare the function before the first call to it.

3.1.2.416 E2357: Reference initialized with 'type1', needs lvalue of type 'type2' (C++)

A reference variable that is not declared constant must be initialized with an lvalue of the appropriate type.

In this case, the initializer either wasn't an lvalue, or its type didn't match the reference being initialized.

3.1.2.417 E2358: Reference member 'member' needs a temporary for initialization (C++)

You provided an initial value for a reference type that was not an lvalue of the referenced type.

This requires the compiler to create a temporary for the initialization.

Because there is no obvious place to store this temporary, the initialization is illegal.

3.1.2.418 E2360: Invalid register combination (e.g. [BP+BX]) (C++)

The built-in assembler detected an illegal combination of registers in an instruction.

These are valid index register combinations:

- [BX]
- [BP]
- [SI]
- [DI]
- [BX+SI]
- [BX+DI]
- [BP+SI]
- [BP+DI]

Other index register combinations are not allowed.

3.1.2.419 E2361: 'specifier' has already been included (C++)

This type specifier occurs more than once in this declaration.

Delete or change one of the occurrences.

3.1.2.420 E2362: Repeat count needs an lvalue (C++)

The expression before the comma (,) in the Watch or Evaluate window must be an accessible region of storage. For example, expressions like this one are not valid:

```
i++,10d
x = y, 10m
```

3.1.2.421 E2363: Attempting to return a reference to local variable 'identifier' (C++)

This C++ function returns a reference type, and you are trying to return a reference to a local (auto) variable.

This is illegal, because the variable referred to disappears when the function exits.

You can return a reference to any static or global variable, or you can change the function to return a value instead.

3.1.2.422 E2364: Attempting to return a reference to a local object (C++)

You attempted to return a reference to a temporary object in a function that returns a reference type. This may be the result of a constructor or a function call.

This object will disappear when the function returns, making the reference illegal.

3.1.2.423 E2365: Member pointer required on right side of .* or ->* (C++)

The right side of a C++ dot-star (.*) or an arrow star (->*) operator must be declared as a pointer to a member of the class specified by the left side of the operator.

In this case, the right side is not a member pointer.

3.1.2.424 E2366: Can't inherit non-RTTI class from RTTI base OR E2367 Can't inherit RTTI class from non-RTTI base (C++)

When virtual functions are present, the RTTI attribute of all base classes must match that of the derived class.

3.1.2.425 E2368: RTTI not available for expression evaluation (C++)

Expressions requiring RTTI are not supported by the expression evaluator in the integrated debugger. This error message is only issued by the expression evaluator (if you try to Inspect, Watch, or Evaluate), not by the compiler.

3.1.2.426 E2371: sizeof may not be applied to a bit field (C++)

sizeof returns the size of a data object in bytes, which does not apply to a bit field.

3.1.2.427 E2372: sizeof may not be applied to a function (C++)

sizeof can be applied only to data objects, not functions.

You can request the size of a pointer to a function.

3.1.2.428 E2373: Bit field cannot be static (C++)

Only ordinary C++ class data members can be declared static, not bit fields.

3.1.2.429 E2374: Function 'function' cannot be static (C++)

Only ordinary member functions and the operators new and delete can be declared static.

Constructors, destructors and other operators must not be static.

3.1.2.430 Stack overflow (C++)

This error is reported when you compile a function with the Test Stack Overflow option on, but there is not enough stack space to

allocate the function's local variables.

This error can also be caused by the following:

- infinite recursion, or
- an assembly language procedure that does not maintain the stack project
- a large array in a function

3.1.2.431 E2376: statement missing (C++)

In a do, for, if, switch, or while statement, the compiler found no left parenthesis after the while keyword or test expression.

3.1.2.432 E2377: statement missing) (C++)

In a do, for, if, switch, or while statement, the compiler found no right parenthesis after the while keyword or test expression.

3.1.2.433 E2378: do-while or for statement missing ; (C++)

In a do or for statement, the compiler found no semicolon after the right parenthesis.

3.1.2.434 E2379: Statement missing ; (C++)

The compiler encountered an expression statement without a semicolon following it.

3.1.2.435 E2380: Unterminated string or character constant (C++)

The compiler found no terminating quote after the beginning of a string or character constant.

3.1.2.436 E2381: Structure size too large (C++)

Your source file declared a structure larger than 64K.

3.1.2.437 E2382: Side effects are not allowed (C++)

Side effects such as assignments, ++, or -- are not allowed in the debugger watch window. A common error is to use x = y (not allowed) instead of x == y to test the equality of x and y.

3.1.2.438 E2383: Switch selection expression must be of integral type (C++)

The selection expression in parentheses in a `switch` statement must evaluate to an integral type (`char, short, int, long, enum`).

You might be able to use an explicit cast to satisfy this requirement.

3.1.2.439 E2433: Specialization after first use of template (C++)

An ANSI C++ rule requires that a specialization for a function template be declared before its first use. This error message is only issued when the ANSI conformance option (-A) is active.

3.1.2.440 E2384: Cannot call near class member function with a pointer of type 'type' (C++)

Also E2385 Cannot call near class member function 'function' with a pointer of type 'type'

Member functions of near classes can't be called via a member pointer.

This also applies to calls using pointers to members.

(Remember, classes are near by default in the tiny, small, and medium memory models.)

Either change the pointer to be near, or declare the class as far.

3.1.2.441 E2390: Type mismatch in parameter 'number' in template class name 'template' (C++)

The actual template argument value supplied for the given parameter did not exactly match the formal template parameter type.

When compiling C++ programs, this message is always preceded by another message that explains the exact reason for the type mismatch.

That other message is usually "Cannot convert 'type1' to 'type2'" but the mismatch might be due to many other reasons.

3.1.2.442 E2391: Type mismatch in parameter 'parameter' in template class name 'template' (C++)

The actual template argument value supplied for the given parameter did not exactly match the formal template parameter type.

When compiling C++ programs, this message is always preceded by another message that explains the exact reason for the type mismatch.

That other message is usually "Cannot convert 'type1' to 'type2'" but the mismatch might be due to many other reasons.

3.1.2.443 E2394: Too few arguments passed to template 'template' (C++)

A template class name was missing actual values for some of its formal parameters.

3.1.2.444 E2395: Too many arguments passed to template 'template' (C++)

A template class name specified too many actual values for its formal parameters.

3.1.2.445 E2396: Template argument must be a constant expression (C++)

A non-type template class argument must be a constant expression of the appropriate type.

This includes constant integral expressions and addresses of objects or functions with external linkage or members.

3.1.2.446 E2401: Invalid template argument list (C++)

This error indicates that an illegal template argument list was found.

In a template declaration, the keyword `template` must be followed by a list of formal arguments enclosed within < and > delimiters.

3.1.2.447 E2400: Nontype template argument must be of scalar type (C++)

A nontype formal template argument must have scalar type; it can have an integral, enumeration, or pointer type.

3.1.2.448 E2415: Template functions may only have 'type-arguments' (C++)

A function template was declared with a non-type argument.

This is not allowed with a template function, as there is no way to specify the value when calling it.

3.1.2.449 E2425: 'member' is not a valid template type member (C++)

A member of a template with some actual arguments that depend on the formal arguments of an enclosing template was found not to be a member of the specified template in a particular instance.

3.1.2.450 E2428: Templates must be classes or functions (C++)

The declaration in a template declaration must specify either a class type or a function.

3.1.2.451 E2432: 'template' qualifier must name a template class or function instance' (C++)

When defining a template class member, the actual arguments in the template class name used as the left operand for the :: operator must match the formal arguments of the template class.

3.1.2.452 E2442: Two consecutive dots (C++)

Because an ellipsis contains three dots (...), and a decimal point or member selection operator uses one dot (.), two consecutive dots cannot legally occur in a C program.

3.1.2.453 E2443: Base class 'class' is initialized more than once (C++)

In a C++ class constructor, the list of initializations following the constructor header includes base class 'class' more than once.

3.1.2.454 E2444: Member 'member' is initialized more than once (C++)

In a C++ class constructor, the list of initializations following the constructor header includes the same member name more than once.

3.1.2.455 E2445: Variable 'identifier' is initialized more than once (C++)

This variable has more than one initialization. It is legal to declare a file level variable more than once, but it can have only one initialization (even if two are the same).

3.1.2.456 E2446: Function definition cannot be a typedef'ed declaration (C++)

In ANSI C, a function body cannot be defined using a typedef with a function Type.

Redefine the function body.

3.1.2.457 E2132: Templates and overloaded operators cannot have C linkage (C++)

You tried to use a linkage specification with a template or overloaded operator. The most common cause for this error message is having the declaration wrapped in an extern "C" linkage specification.

3.1.2.458 E2447: 'identifier' must be a previously defined enumeration tag (C++)

This declaration is attempting to reference 'ident' as the tag of an enum type, but it has not been so declared.

Correct the name, or rearrange the declarations.

3.1.2.459 E2448: Undefined label 'identifier' (C++)

The named label has a `goto` in the function, but no label definition.

3.1.2.460 E2449: Size of 'identifier' is unknown or zero (C++)

This identifier was used in a context where its size was needed.

A struct tag might only be declared (the struct not defined yet), or an extern array might be declared without a size.

It's illegal then to have some references to such an item (like sizeof) or to dereference a pointer to this type.

Rearrange your declaration so that the size of 'identifier' is available.

3.1.2.461 E2450: Undefined structure 'structure' (C++)

The named structure was used in the source file, probably on a pointer to a structure, but had no definition in the source file.

This is probably caused by a misspelled structure name or a missing declaration.

3.1.2.462 E2451: Undefined symbol 'identifier' (C++)

The named identifier has no declaration.

Possible Causes

- Actual declaration of identifier has been commented out.
- Misspelling, either at this point or at the declaration.
- An error in the declaration of the identifier.
- The header file in which the identifier is declared was not included using `#include`

Tools to help track down the problem:

GREP (see page 170)

3.1.2.463 E2453: Size of the type 'identifier' is unknown or zero (C++)

This type was used in a context where its size was needed.

For example, a struct tag might only be declared (the struct not defined yet).

It's illegal then to have some references to such an item (like sizeof) or to dereference a pointer to this type.

Rearrange your declarations so that the size of this type is available.

3.1.2.464 E2452: Size of the type is unknown or zero (C++)

This error message indicates that an array of unspecified dimension nested within another structure is initialized and the `-A` (ANSI) switch is on. For example:

```
struct
{
char a[]; //Size of 'a' is unknown or zero
}
b = { "hello" }; //Size of the type is
//unknown or zero
```

3.1.2.465 E2454: union cannot be a base type (C++)

A union can't be used as a base type for another class type.

3.1.2.466 E2455: union cannot have a base type (C++)

In general, a C++ class can be of union type, but such a class can't be derived from any other class.

3.1.2.467 E2456: Union member 'member' is of type class with 'constructor' (or destructor, or operator =) (C++)

A union can't contain members that are of type class with user-defined constructors, destructors, or operator =.

3.1.2.468 E2461: '%s' requires run-time initialization/finalization (C++)

This message is issued when a global variable that is declared as __thread (a Win32-only feature) or a static data member of a template class is initialized with a non-constant initial value.

This message is also issued when a global variable that is declared as __thread (a Win32-only feature) or a static data member of a template class has the type class with constructor or destructor.

3.1.2.469 E2464: 'virtual' can only be used with member functions (C++)

A data member has been declared with the `virtual` specifier.

Only member functions can be declared virtual.

For example:

```
class myclass
{
public:
```

```
    virtual int a;    //error
};
```

3.1.2.470 E2465: unions cannot have virtual member functions (C++)

A union can't have virtual functions as its members.

3.1.2.471 E2466: void & is not a valid type (C++)

A reference always refers to an object, but an object cannot have the type void.

Thus, the type void is not allowed.

3.1.2.472 E2467: 'Void function' cannot return a value (C++)

A function with a return type void contains a return statement that returns a value; for example, an int.

Default = displayed

3.1.2.473 E2468: Value of type void is not allowed (C++)

A value of type `void` is really not a value at all, so it can't appear in any context where an actual value is required.

Such contexts include the following:

- the right side of an assignment
- an argument of a function
- the controlling expression of an if, for, or while statement.

3.1.2.474 E2469: Cannot use tiny or huge memory model with Windows (C++)

The compiler no longer issues this error.

3.1.2.475 E2006: CodeGuarded programs must use the large memory model and be targeted for Windows (C++)

The compiler no longer issues this error.

3.1.2.476 E2269: The function 'function' is not available (C++)

You tried to call a function that is known to the evaluator, but which was not present in the program being debugged, for example, an inline function.

3.1.2.477 E2124: Invalid function call (C++)

A requested function call failed because the function is not available in the program, a parameter cannot be evaluated, and so on. The evaluator issues this message.

3.1.2.478 E2213: Invalid 'expression' in scope override (C++)

The evaluator issues this message when there is an error in a scope override in an expression you are watching or inspecting. You can specify a symbol table, a compilation unit, a source file name, etc. as the scope of the expression, and the message will appear whenever the compiler cannot access the symbol table, compilation unit, or whatever.

3.1.2.479 E2236: Missing 'identifier' in scope override (C++)

The syntax of a scope override is somehow incomplete. The evaluator issues this message.

3.1.2.480 Pure virtual function called (C++)

This is a runtime error. It is generated if the body of a pure virtual function was never generated and somehow the compiler tried to call it.

3.1.2.481 E2095: String literal not allowed in this context (C++)

This error message is issued by the evaluator when a string literal appears in a context other than a function call.

3.1.2.482 Unexpected termination during compilation [Module Seg#:offset] OR Unexpected termination during linking [Module Seg#:offset] (C++)

If either of these errors occur, it indicates a catastrophic failure of the CodeGear tools. You should contact CodeGear to report the problem and to find a potential work around for your specific case. By isolating the test case as well as possible, you will increase the chance for either CodeGear or yourself to find a work around for the problem.

Commonly, compiler failures can be worked around by moving the source code that is currently being compiled. Simple cases might be switching the order of variable declarations, or functions within the source module. Moving the scope and storage of variables also helps in many cases.

For linker failures, you can reduce the amount of debugging information that the linker has to work with. Try compiling only one or two modules with debug information instead of an entire project.

Similarly, switching the order in which object modules are handed to the linker can work around the problem. The IDE hands objects to the linker in the order that they are listed in the project tree. Try moving a source up or down in the list.

3.1.2.483 E2012: Cannot take address of 'main' (C++)

In C++, it is illegal to take the address of the main function.

3.1.2.484 E2016: Ambiguous override of virtual base member 'base_function': 'derived_function' (C++)

A virtual function in a virtual base class was overridden with two or more different functions along different paths in the inheritance hierarchy. For example,

```
struct VB
{
virtual f();
};
struct A:virtual VB
{
virtual f();
};
//{
struct B:virtual VB
virtual f();
}
```

3.1.2.485 E2021: Array must have at least one element (C++)

ANSI C and C++ require that an array be defined to have at least one element (objects of zero size are not allowed).

An old programming trick declares an array element of a structure to have zero size, then allocates the space actually needed with malloc.

You can still use this trick, but you must declare the array element to have (at least) one element if you are compiling in strict ANSI mode.

Declarations (as opposed to definitions) of arrays of unknown size are still allowed.

Example

```
char ray[];         /* definition of unknown size -- ILLEGAL */
char ray[0];        /* definition of 0 size -- ILLEGAL */
extern char ray[];  /* declaration of unknown size -- OK */
```

3.1.2.486 E2023: Array of references is not allowed (C++)

It is illegal to have an array of references, because pointers to references are not allowed and array names are coerced into pointers.

3.1.2.487 E2032: Illegal use of closure pointer (C++)

A closure pointer variable is used incorrectly. Closure variables have limited usage. For instance, you can assign a function to a closure variable, and execute that function through the closure variable, but you cannot use a closure variable like a pointer variable.

3.1.2.488 E2040: Declaration terminated incorrectly (C++)

A declaration has an extra or incorrect termination symbol, such as a semicolon placed after a function body.

A C++ member function declared in a class with a semicolon between the header and the opening left brace also generates this error.

3.1.2.489 E2047: Bad 'directive' directive syntax (C++)

A macro definition starts or ends with the ## operator, or contains the # operator that is not followed by a macro argument name.

An example of this might be:

```
Bad ifdef directive syntax
```

Note that an `#ifdef` directive must contain a single identifier (and nothing else) as the body of the directive.

Another example is:

```
Bad undef directive syntax
```

An `#undef` directive must also contain only one identifier as the body of the directive.

3.1.2.490 E2049: Class type 'type' cannot be marked as __declspec(delphireturn) (C++)

Classes marked as delphireturn are special classes that the compiler needs to recognize by name. These classes are predefined in the headers.

Some of the delphireturn classes are Variant, AnsiString, and Currency.

You cannot mark user-defined classes as delphireturn.

3.1.2.491 E2052: Dynamic function 'function' conflicts with base class 'class' (C++)

Some of the modifiers of this dynamic function conflict with the definition of the same function in the base class. The two functions should have the same modifiers. The following modifiers (among others) can cause conflicts:

- __export
- __import
- declspec(naked)
- declspec(package)
- __fastcall

3.1.2.492 E2057: Exception specification not allowed here (C++)

Function pointer type declarations are not allowed to contain exception specifications.

3.1.2.493 E2058: Exception handling variable may not be used here (C++)

An attempt has been made to use one of the exception handling values that are restricted to particular exception handling constructs, such as GetExceptionCode().

3.1.2.494 E2065: Using namespace symbol 'symbol' conflicts with intrinsic of the same name (C++)

If you define a function in a namespace, which has a name that might be replaced by a call to an intrinsic when -Oi is on, it is not permitted to have a "using" declaration which refers to that member.

For example, calls to "strcmp" are replaced by the intrinsic "__strcmp__" when -Oi is on. This means that the declaration "using N::strcmp;" would become "using N::__strcmp__", since the token replacement happens before the compiler's parser ever sees the tokens.

An error displays in this case, because the compiler doesn't know how to process "N::__strcmp__".

3.1.2.495 E2067: 'main' must have a return type of int (C++)

In C++, function main has special requirements, one of which is that it cannot be declared with any return type other than int.

3.1.2.496 E2073: Nothing allowed after pragma option pop (C++)

The #pragma option pop can only be followed by comments, blanks, or end of line.

3.1.2.497 E2091: Functions cannot return arrays or functions (C++)

A function was defined to return an array or a function. Check to see if either the intended return was a pointer to an array or function (and perhaps the * is missing) or if the function definition contained a request for an incorrect datatype.

3.1.2.498 E2093: Operator 'operator' not implemented in type 'type' for arguments of the same type (C++)

The operator you are calling is not defined in this class. When you have an expression: x + x, where x is of type class X, the operator + has to be defined in class X and be accessible.

3.1.2.499 E2094: Operator 'operator' not implemented in type 'type' for arguments of type 'type' (C++)

The operator you are calling is not defined in this class. When you have an expression: x + x, where x is of type class X, the operator + has to be defined in class X and be accessible.

3.1.2.500 E2097: Explicit instantiation only allowed at file or namespace scope (C++)

The explicit instantiation operator "template" can only be used within global or namespace scope. It cannot be used to qualify a local class or a class member, for example.

3.1.2.501 E2098: Explicit specialization declarator "template<>" now required (C++)

When specializing a function, such as providing the definition for "foo<int>", so that foo behaves specially which called for the "int" argument, now requires that the declaration begin with an explicit specialization operator.

3.1.2.502 E2099: Explicit specialization only allowed at file or namespace scope (C++)

The explicit specialization operator template<> can only be used within global or namespace scope. It cannot be used to qualify a local class or a class member, for example.

3.1.2.503 E2101: 'export' keyword must precede a template declaration (C++)

The 'export' keyword can only occur before the keyword "template" ina template declaration. It cannot be used anywhere else.

3.1.2.504 E2103: Explicit instantiation must be used with a template class or function (C++)

The explicit instantiation operator "template" can only be used to refer to templates. It cannot be used with non-templates.

3.1.2.505 E2106: Explicit specialization must be used with a template class or function (C++)

The explicit specialization operator template<> can only be used in front of a template class or function. Using it with a normal class means nothing, and hence generates an error.

3.1.2.506 E2112: Unknown unit directive: 'directive' (C++)

You cannot use this name as a unit directive. Instead use one of the following unit directives: weak, smart_init, or deny.

3.1.2.507 E2118: Bit fields must have integral type (C++)

In C++, bit fields must have an integral type. This includes enumerations.

3.1.2.508 E2120: Cannot call 'main' from within the program (C++)

C++ does not allow recursive calls of main( ).

3.1.2.509 E2125: Compiler could not generate copy constructor for class 'class' OR Compiler could not generate default constructor for class 'class' OR Compiler could not generate operator = for class 'class' (C++)

Sometimes the compiler is required to generate a member function for the user.

Whenever such a member function can't be generated due to applicable language rules, the compiler issues one of these error messages.

3.1.2.510 E2130: Circular property definition (C++)

Indicates that a property definition relies directly or indirectly on itself.

Example

```
struct pbase
{
     int __property ip1 = {read = ip2, write = ip2};
     int __property ip2 = {read = ip1, write = ip1};
};
```

The above code sample will cause this error message on any usage of ip1 or ip2.

3.1.2.511 E2131: Objects of type 'type' cannot be initialized with { } (C++)

Ordinary C structures can be initialized with a set of values inside braces.

C++ classes can only be initialized with constructors if the class has constructors, private members, functions, or base classes that are virtual.

3.1.2.512 E2148: Default argument value redeclared for parameter 'parameter' (C++)

When a parameter of a C++ function is declared to have a default value, this value can't be changed, redeclared, or omitted in any other declaration for the same function.

3.1.2.513 E2149: Default argument value redeclared (C++)

When a parameter of a C++ function is declared to have a default value, this value can't be changed, redeclared, or omitted in any other declaration for the same function.

3.1.2.514 E2151: Type mismatch in default value for parameter 'parameter' (C++)

The default parameter value given could not be converted to the type of the parameter.

The message "Type mismatch in default argument value" is used when the parameter was not given a name.

When compiling C++ programs, this message is always preceded by another message that explains the exact reason for the type mismatch.

That other message is usually "Cannot convert 'type1' to 'type2'" but the mismatch might be due to many other reasons.

3.1.2.515 E2157: Deleting an object requires exactly one conversion to pointer operator (C++)

If a person uses the 'delete' operator on an object (note: not a pointer to an object, but an object itself), the standard requires that object to define exactly one "conversion to pointer operator" which will yield the pointer that gets freed. For example:

```
char *a = new char[10];
class foo {
public:
    operator char *() { return a; }
};

int main() {
    delete[] x;
}
```

Since 'x' is not a pointer, but an object, the compiler will delete 'a', because that is what the pointer conversion operator for the object yields. Having more than one conversion to pointer operator is illegal, because the compiler would not know which one to call.

3.1.2.516 E2173: Duplicate handler for 'type1', already had 'type2' (C++)

It is not legal to specify two handlers for the same type.

3.1.2.517 E2174: The name handler must be last (C++)

In a list of catch handlers, if the specified handler is present, it must be the last handler in the list (that is, it cannot be followed by any more catch handlers).

3.1.2.518 E2177: Redeclaration of #pragma package with different arguments (C++)

You can have multiple #pragma package statements in a source file as long as they have the same arguments. This error occurs if the compiler encounters more than one #pragma package with different arguments in each.

3.1.2.519 E2178: VIRDEF name conflict for 'function' (C++)

The compiler must truncate mangled names to a certain length because of a name length limit that is imposed by the linker. This truncation may (in very rare cases) cause two names to mangle to the same linker name. If these names happen to both be VIRDEF names, the compiler issues this error message. The simplest workaround for this problem is to change the name of 'function' so that the conflict is avoided.

3.1.2.520 E2180: Dispid number already used by identifier (C++)

Dispids must be unique and the compiler checks for this.

Example

```
struct__declspec(delphiclass) clxclass
{
__automated:
int __fastcall foo1(void) __dispid(42);// OK
int __fastcall foo2(void) __dispid(42);// Error
};
```

3.1.2.521 E2181: Cannot override a 'dynamic/virtual' with a 'dynamic/virtual' function (C++)

When you declare a function dynamic, you cannot override this function in a derived class with a virtual function of the same name and type. Similarly when the function is declared virtual, you cannot override it with a dynamic one in a derived class.

3.1.2.522 E2202: Goto into an exception handler is not allowed (C++)

It is not legal to jump into a try block, or an exception handler that is attached to a try block.

3.1.2.523 E2205: Illegal type type in __automated section (C++)

Only certain types are allowed in __automated sections.

Example

```
struct__declspec(delphiclass) clxclass
{
__automated:
int__fastcall fooInt(int);// OK
long__fastcall fooLong(long);// Error: long illegal
};
```

3.1.2.524 E2242: Specifier requires Delphi style class type (C++)

The stored, default, and nodefault storage specifiers are only allowed within property declarations of Delphi style class types.

Example

```
struct regclass
{
     int __property ip1 = { stored  = false }; // Error
     int __property ip2 = { default = 42    }; // Error
     int __property ip3 = { nodefault       }; // Error
};
struct __declspec(delphiclass) clxclass
{
     int __property ip1 = { stored  = false }; // OK
     int __property ip2 = { default = 42    }; // OK
     int __property ip3 = { nodefault       }; // OK
};
```

3.1.2.525 E2247: 'member' is not accessible (C++)

You are trying to reference C++ class member 'member,' but it is private or protected and can't be referenced from this function.

This sometimes happens when you attempt to call one accessible overloaded member function (or constructor), but the arguments match an inaccessible function.

The check for overload resolution is always made before checking for accessibility.

If this is the problem, try an explicit cast of one or more parameters to select the desired accessible function.

Virtual base class constructors must be accessible within the scope of the most derived class. This is because C++ always constructs virtual base classes first, no matter how far down the hierarchy they are. For example:

```
class A {
public:
   A();
};
class B : private virtual A {};
class C : private B {
public:
C();
};
C::C() {} // error, A::A() is not accessible
```

Since A is private to B, which is private to C, it makes A's constructor not accessible to C. However, the constructor for C must be able to call the constructors for its virtual base class, A. If B inherits A publicly, the above example would compile.

3.1.2.526 E2248: Cannot find default constructor to initialize array element of type 'class' (C++)

When declaring an array of a class that has constructors, you must either explicitly initialize every element of the array, or the class must have a default constructor.

The compiler will define a default constructor for a class unless you have defined any constructors for the class.

3.1.2.527 E2251: Cannot find default constructor to initialize base class 'class' (C++)

Whenever a C++ derived class 'class2' is constructed, each base class 'class1' must first be constructed.

If the constructor for 'class2' does not specify a constructor for 'class1' (as part of 'class2's' header), there must be a constructor class1::class1() for the base class.

This constructor without parameters is called the default constructor.

The compiler will supply a default constructor automatically unless you have defined any constructor for class 'class1'.

In that case, the compiler will not supply the default constructor automatically--you must supply one.

```
class Base {
public:
   Base(int) {}
};
class Derived = public Base {
   Derived():Base(1) {}
}
// must explicitly call the Base constructor, or provide a
// default constructor in Base.
```

Class members with constructors must be initialized in the class' initializer list, for example:

```
class A {
public
   A( int );
};
class B {
public:
   A a;
   B() : a( 3 ) {}; //ok
};
```

3.1.2.528 E2252: 'catch' expected (C++)

In a C++ program, a 'try' block must be followed by at least one 'catch' block.

3.1.2.529 E2253: Calling convention must be attributed to the function type, not the closure (C++)

The calling convention is in the wrong place in the closure declaration. For example,

```
int __fastcall (__closure * x)()
```

will compile, but

```
int (__fastcall __closure * x)()
```

will not.

3.1.2.530 E2261: Use of dispid with a property requires a getter or setter (C++)

This property needs either a getter or a setter.

3.1.2.531 E2262: '__except' or '__finally' expected following '__try' (C++)

In C, a '__try block' must be followed by a '__except' or '__finally' handler block.

3.1.2.532 E2270: > expected (C++)

A new-style cast (for example, dynamic_cast) was found with a missing closing ">".

3.1.2.533 E2273: 'main' cannot be declared as static or inline (C++)

You cannot make main static or inline. For example, you cannot use static int main() or inline int main().

3.1.2.534 E2281: Identifier1 requires definition of Identifier2 as a pointer type (C++)

To use Identifier1, there needs to be a definition for Identifier2, which is a type.

Example where __classid is the first identifier and TClass, which can be found in clx.h, is the second one:

```
// #include <clx/clx.h> missing
struct __declspec(delphiclass)bar
{
     virtual int barbara(void);
};
void *foo(void)
{
     return classid(bar);    // Error
}
```

3.1.2.535 E2289: __published or __automated sections only supported for Delphi classes (C++)

The compiler needs to generate a special kind of vtable for classes containing __published and __automated sections. Therefore, these sections are only supported for Delphi style classes.

Example

```
structregclass
{
int mem;
__published:// Error: no Delphi style class
int __property ip = { read = mem, write = mem };
```

```
};
struct__declspec(delphiclass) clxclass
{
int mem;
__published:// OK
int __property ip = { read = mem, write = mem };
};
```

3.1.2.536 E2298: Cannot generate 'function' from template function 'template' (C++)

A call to a template function was found, but a matching template function cannot be generated from the function template.

3.1.2.537 E2301: Cannot use templates in closure arguments -- use a typedef (C++)

When declaring a closure type, the arguments passed to that closure must be of a simple type. Templates are not accepted. To pass a reference to an object of template type to a closure, you must declare a typedef, which counts as a simple type name.

Example

```
typedef my_class<int> mci;
typedef void (__closure * func) (const mci& object);
```

3.1.2.538 E2307: Type 'type' is not a defined class with virtual functions (C++)

A dynamic_cast was used with a pointer to a class type that is either undefined, or doesn't have any virtual member functions.

3.1.2.539 E2315: 'Member' is not a member of 'class', because the type is not yet defined (C++)

The member is being referenced while the class has not been fully defined yet. This can happen if you forward declare class X, declare a pointer variable to X, and reference a member through that pointer; for example:

```
class X;
X * oneX;
int test() { return oneX->i; }
```

3.1.2.540 E2318: 'type' is not a polymorphic class type (C++)

This error is generated if the -RT compiler option (for runtime type information) is disabled and either

dynamic_cast was used with a pointer to a class

or

you tried to delete a pointer to an object of a class that has a virtual destructor

3.1.2.541 E2323: Illegal number suffix (C++)

A numeric literal is followed by a suffix that is not recognized by the compiler.

Example

```
int i = 1234i15;   // Error: no i15 suffix
int j = 1234i16;   // OK
```

3.1.2.542 E2326: Use __declspec(spec1[, spec2]) to combine multiple __declspecs (C++)

When you want to use several __declspec modifiers, the compiler will complain if you don't combine them into one __declspec. For example:

```
int __declspec(__import) __declspec(delphiclass) X
```

will give an error. Use the following instead:

```
int __declspec(__import, delphiclass) X
```

3.1.2.543 E2328: Classes with properties cannot be copied by value (C++)

This error occurs if you attempt to use the default assignment operator. For example, the following code generates this error given two labels on a form:

```
*Label1->Font = *Label2->Font;
```

3.1.2.544 E2331: Number of allowable option contexts exceeded (C++)

You have interspersed too many source-code option changes (using #pragma option) between template declarations. For example:

```
#pragma option -x
template<class T> class foo1 { };
#pragma option -a3
template<class T> class foo2 { };
#pragma option -b
template<class T> class foo3 { };
#pragma option -k-
```

You need to break your source code into smaller files.

3.1.2.545 E2332: Variable 'variable' has been optimized and is not available (C++)

You have tried to inspect, watch, or otherwise access a variable which the optimizer removed.

This variable is never assigned a value and has no stack location.

3.1.2.546 E2476: Cannot overload 'function' (C++)

You cannot overload the specified function. This error is displayed if you tried to declare a function with the same name as another function, but the redeclaration is not legal. For example, if both functions have the 'extern "C"' linkage type, only one 'extern "C"' function can have a given name.

3.1.2.547 E2346: 'x' access specifier of property 'property' must be a member function (C++)

Only member functions or data members are allowed in access specifications of properties.

Example

```
int GlobalGetter(void)
{
     return 0;
}
struct pbase
{
     intMemberGetter(void) {return 1;}
     int __property ip1 = { read = GlobalGetter }; // Error
     int __property ip2 = { read = MemberGetter }; // OK
};
```

3.1.2.548 E2347: Parameter mismatch in access specifier 'specifier' of property 'property' (C++)

The parameters of the member function used to access a property don't match the expected parameters.

Example

```
structpbase
{
       voidSetter1(void){}
       voidSetter2(int){}
     int __property ip1 = { write = Setter1 }; // Error
     int __property ip2 = { write = Setter2 }; // OK
};
```

3.1.2.549 E2348: Storage specifier not allowed for array properties (C++)

Array properties cannot have a storage specification.

Example

```
struct pbase
{
    int __property ap[char *] =
                           { stored = false }; // Error
};
```

3.1.2.550 E2351: Static data members not allowed in __published or __automated sections (C++)

Only nonstatic data members and member functions are allowed in __published or __automated sections.

Example

```
struct__declspec(delphiclass) clxclass
{
__published:
static intstaticDataMember;// Error
};
```

3.1.2.551 E2353: Class 'classname' is abstract because of 'member = 0' (C++)

This message is issued immediately after the "Cannot create instance of abstract class 'classname' error message and is intended to make it easier to figure out why a particular class is considered abstract by the compiler.

For example, consider the following example of an illegal attempt to instantiate an abstract class:

```
struct VB
{
virtualvoid  f() = 0;
virtualvoid  g() = 0;
virtualvoid  h() = 0;
};
struct D1 : virtual VB
{
void   f();
};
struct D2 : virtual VB
{
void   h();
};
struct DD : D1, D2
{
}
v;   // error 'DD' is an abstract class
```

The above code will cause the following two error messages:

```
Error TEST.CPP 21: Cannot create instance of abstract class 'DD'
Error TEST.CPP 21: Class 'DD' is abstract because of 'VB::g() = 0'
```

3.1.2.552 E2359: Reference member 'member' initialized with a non-reference parameter (C++)

An attempt has been made to bind a reference member to a constructor parameter. Since the parameter will cease to exist the moment the constructor returns to its caller, this will not work correctly.

3.1.2.553 E2369: Cannot use the result of a property assignment as an rvalue' (C++)

The result of a property assignment is an lvalue. This implies for instance that chained assignments of properties is not allowed; for example, x = y = 5, where both x and y are properties. Certain embedded assignments of properties can also produce errors; for example, x != (y = z), where y is a property.

3.1.2.554 E2370: Simple type name expected (C++)

To ensure interoperability between Delphi and C++, there are restrictions on the type names mentioned in the parameter lists of published closure types. The parameter types have to be simple type names with optional const modifier and pointer or reference notation.

So when declaring a closure type, the arguments passed to that closure must be of a simple type. For example, templates are not accepted. To pass a reference to an object of template type to a closure, you must declare a typedef, which counts as a simple type name.

Example

```
struct __declspec(delphiclass) foo
{
     typedef void __fastcall (__closure *foo1)(SomeTemplateType<int> *);
     typedef SomeTemplateType<int> SimpleTypeName;
     typedef void __fastcall (__closure *foo2)(SimpleTypeName *);
published:
     __property foo1 prop1;  // Error
     __property foo2 prop2;  // OK
};
```

3.1.2.555 E2398: Template function argument 'argument' not used in argument types (C++)

The given argument was not used in the argument list of the function.

The argument list of a template function must use all of the template formal arguments; otherwise, there is no way to generate a template function instance based on actual argument types.

3.1.2.556 E2419: Error while instantiating template 'template' (C++)

An error occurred during the instantiation of a particular template. This message always follows some other error message that indicates what actually went wrong. This message is displayed to help track down which template instantiation introduced the problem.

3.1.2.557 E2424: Template class nesting too deep: 'class' (C++)

The compiler imposes a certain limit on the level of template class nesting. This limit is usually only exceeded through a recursive template class dependency.

When this nesting limit is exceeded, the compiler issues this error message for all of the nested template classes. This usually

makes it easy to spot the recursion.

This error message is always followed by the fatal error "Out of memory".

3.1.2.558 E2457: Delphi style classes must be caught by reference (C++)

You can only catch a Delphi style object by pointer.

Example

```
void foo(TObject *p)
{
     try
     {
          throw(p);
     }
     catch    (TObject o)    // Error
     {
     }
     catch  (TObject *op)    // OK
     {
     }
}
```

3.1.2.559 E2458: Delphi classes have to be derived from Delphi classes (C++)

You cannot derive a Delphi style class from a non-Delphi style class.

Example

```
struct base// base not a Delphi style class
{
intbasemem;
};
struct __declspec(delphiclass) derived : base // or
{
intderivedmem;
};
```

3.1.2.560 E2459: Delphi style classes must be constructed using operator new (C++)

Delphi style classes cannot be statically defined. They have to be constructed on the heap.

Example

```
voidfoo(void)
{
     Tobject   o1;     // Error;
     Tobject  *o2 = new TObject();
}
```

3.1.2.561 E2460: Delphi style classes require exception handling to be enabled (C++)

If you are using Delphi style classes in your program, you cannot turn off exception handling (compiler option `-x-`) when compiling your source code.

3.1.2.562 E2463: 'base' is an indirect virtual base class of 'class' (C++)

You can't create a pointer to a C++ member of a virtual base class.

You have attempted to create such a pointer (either directly, or through a cast) and access an inaccessible member of one of your base classes.

3.1.2.563 Null pointer assignment (C++)

When a small or medium memory model program exits, a check is made to determine if the contents of the first few bytes within the program's data segment have changed. These bytes would never be altered by a working program. If they have been changed, this message is displayed to inform you that (most likely) a value was stored to an uninitialized pointer.

The program might appear to work properly in all other respects; however, this is a serious bug which should be attended to immediately. Failure to correct an uninitialized pointer can lead to unpredictable behavior (including locking the computer up in the large, compact, and huge memory models).

You can use the integrated debugger to track down null pointers.

3.1.2.564 E2268: Call to undefined function 'function' (C++)

Your source file declared the current function to return some type other than `void` in C++ (or `int` in C), but the compiler encountered a return with no value. All `int` functions are exempt in C because in old versions of C, there was no `void` type to indicate functions that return nothing.

3.1.2.565 E2375: Assembler stack overflow (C++)

The assembler ran out of memory during compilation. Review the portion of code flagged by the error message to ensure that it uses memory correctly.

3.1.2.566 Initializing enumeration with type (C++)

You're trying to initialize an enum variable to a different type. For example,

```
enum count { zero, one, two } x = 2;
```

will result in this warning, because 2 is of type int, not type enum count. It is better programming practice to use an enum identifier instead of a literal integer when assigning to or initializing enum types.

This is an error, but is reduced to a warning to give existing programs a chance to work.

3.1.2.567 <name> is not a valid identifier (C++)

The identifier name is invalid. Ensure that the first character is a letter or an underscore (_). The characters that follow must be letters, digits, or underscores, and there can not be any spaces in the identifier.

3.1.2.568 Example for "Temporary used ..." error messages (C++)

In this example, function f requires a reference to an int, and c is a char:

```
f(int&);
char c;
f(c);
```

Instead of calling f with the address of c, the compiler generates code equivalent to the C++ source code:

```
int X = c, f(X);
```

3.1.2.569 Application is running (C++)

The application you tried to run is already running.

For Windows, make sure the message loop of the program has properly terminated.

```
PostQuitMessage(0);
```

3.1.2.570 Printf/Scanf floating-point formats not linked (C++)

Floating-point formats contain formatting information that is used to manipulate floating-point numbers in certain runtime library functions, such as scanf() and atof(). Typically, you should avoid linking the floating-point formats (which take up about 1K) unless they are required by your application. However, you must explicitly link the floating-point formats for programs that manipulate fields in a limited and specific way.

Refer to the following list of potential causes (listed from most common to least common) to determine how to resolve this error:

- CAUSE: Floating point set to None. You set the floating-point option to None when it should be set to either Fast or Normal.
- FIX: Set Floating Point to Fast or Normal.
- CAUSE: Either the compiler is over-optimizing or the floating-point formats really do need to be linked. You need the floating-point formats if your program manipulates floats in a limited and specific way. Under certain conditions, the compiler will ignore floating-point usage in scanf(). For example, this may occur when trying to read data into a float variable that is part of an array contained in a structure.
- FIX: Add the following code to one source module:

```
extern _floatconvert;
#pragma extref _floatconvert
```

CAUSE: You forgot to put the address operator & on the scanf variable expression. For example:

```
float foo;
scanf("%f", foo);
```

FIX: Change the code so that the & operator is used where needed. For example, change the above code to the following:

```
float foo;
scanf("%f", &foo);
```

3.1.2.571 W8000: Ambiguous operators need parentheses (C++)

(Command-line option to display warning: -wamb)

This warning is displayed whenever two shift, relational, or bitwise-Boolean operators are used together without parentheses.

Also, an addition or subtraction operator that appears without parentheses with a shift operator will produce this warning.

3.1.2.572 W8060: Possibly incorrect assignment (C++)

(Command-line option to suppress warning: -w-pia)

This warning is generated when the compiler encounters an assignment operator as the main operator of a conditional expression (part of an if, while, or do-while statement).

This is usually a typographical error for the equality operator.

If you want to suppress this warning, enclose the assignment in parentheses and compare the whole thing to zero explicitly.

For example, this code

```
if (a = b) ...
```

should be rewritten as

```
if ((a = b) != 0) ...
```

3.1.2.573 W8002: Restarting compile using assembly (C++)

(Command-line option to suppress warning: -w-asc)

The compiler encountered an asm with no accompanying or `#pragma` inline statement.

The compile restarts using assembly language capabilities.

Default = On

3.1.2.574 W8003: Unknown assembler instruction (C++)

(Command-line option to suppress warning: -w-asm)

The compiler encountered an inline assembly statement with a disallowed opcode or an unknown token. Check the spelling of the opcode or token.

`Note:` You will get a separate error message from the assembler if you entered illegal assembler source code.

This warning is off by default.

3.1.2.575 W8052: Base initialization without a class name is now obsolete (C++)

(Command-line option to suppress warning: -w-obi)

Early versions of C++ provided for initialization of a base class by following the constructor header with just the base class

constructor parameter list.

It is now recommended to include the base class name.

This makes the code much clearer, and is required when you have multiple base classes.

Old way

```
derived::derived(int i) : (i, 10) { ... }
```

New way

```
derived::derived(int i) : base(i, 10) { ... }
```

3.1.2.576 E2117: Bit fields must be signed or unsigned int (C++)

(Command-line option to display warning: -wbbf)

In ANSI C, bit fields may not be of type signed char or unsigned char.

When you're not compiling in strict ANSI mode, the compiler allows these constructs, but flags them with this warning.

3.1.2.577 W8064: Call to function with no prototype (C++)

(Command-line option to suppress warning: -w-pro)

This message is given if the "Prototypes required" warning is enabled and you call a function without first giving a prototype for that function.

3.1.2.578 W8065: Call to function 'function' with no prototype (C++)

This message is given if the "Prototypes required" warning is enabled and you call function 'function' without first giving a prototype for that function.

3.1.2.579 W8009: Constant is long (C++)

(Command-line option to display warning: -wcln)

The compiler encountered one of the following:

- a decimal constant greater than 32,767 or
- an octal, hexadecimal, or decimal constant greater than 65,535 without a letter l or L following it

The constant is treated as a long.

3.1.2.580 W8008: Condition is always true OR W8008 Condition is always false (C++)

(Command-line option to suppress warning: -w-ccc)

Whenever the compiler encounters a constant comparison that (due to the nature of the value being compared) is always true or false, it issues this warning and evaluates the condition at compile time.

For example:

```
void proc(unsigned x){
  if (x >= 0)        /* always 'true' */
  {
     ...
  }
}
```

3.1.2.581 W8012: Comparing signed and unsigned values (C++)

(Command-line option to suppress warning: -w-csu)

Since the ranges of signed and unsigned types are different the result of an ordered comparison of an unsigned and a signed value might have an unexpected result.

Example

```
#pragma warn +csu
boolfoo(unsigned u, int i)
{
return u < i;
}
```

3.1.2.582 W8010: Continuation character \ found in // comment (C++)

(Command-line option to suppress warning: -w-com)

This warning message is issued when a C++ // comment is continued onto the next line with backslash line continuation.

The intention is to warn about cases where lines containing source code unintentionally become part of a comment because that comment happened to end in a backslash.

If you get this warning, check carefully whether you intend the line after the // comment to be part of the comment. If you don't, either remove the backslash or put some other character after it. If you do, it's probably better coding style to start the next comment line with // also.

The warning can be disabled altogether with #pragma warn -com.

3.1.2.583 W8080: 'identifier' is declared but never used (C++)

(Command-line option to display warning: -wuse)

The specified identifier was never used. This message can occur in the case of either local or static variables. It occurs when the source file declares the named local or static variable as part of the block just ending, but the variable was never used.

In the case of local variables, this warning occurs when the compiler encounters the closing brace of the compound statement or function. In the case of static variables, this warning occurs when the compiler encounters the end of the source file.

For example:

```
// Need to compile with -w to make this warning show up!
#pragma option -w
int foo()
{
        int x;
        return 0;
}
```

3.1.2.584 W8014: Declaration ignored (C++)

(Command-line option to suppress warning: -w-dig)

An error has occurred while using the command-line utility H2ASH. See the online file "tsm_util.txt" for further information about this utility.

Default = On

3.1.2.585 W8068: Constant out of range in comparison (C++)

(Command-line option to suppress warning: -w-rng)

Your source file includes a comparison involving a constant sub-expression that was outside the range allowed by the other sub-expression's type.

For example, comparing an unsigned quantity to -1 makes no sense.

To get an unsigned constant greater than 32,767 (in decimal), you should either

- cast the constant to unsigned--for example, (unsigned) 65535, or
- append a letter u or U to the constant--for example, 65535u.

Whenever this message is issued, the compiler still generates code to do the comparison.

If this code ends up always giving the same result (such as comparing a char expression to 4000), the code will still perform the test.

3.1.2.586 W8016: Array size for 'delete' ignored (C++)

(Command-line option to suppress warning: -w-dsz)

The C++ IDE issues this warning when you've specified the array size when deleting an array.

With the new C++ specification, you don't need to make this specification. The compiler ignores this construct.

This warning lets older code compile.

3.1.2.587 W8082: Division by zero (C++)

(Command-line option to suppress warning: -w-zdi)

A divide or remainder expression had a literal zero as a divisor.

3.1.2.588 W8018: Assigning 'type' to 'enumeration' (C++)

(Command-line option to suppress warning: -w-eas)

Assigning an integer value to an enum type.

This is an error in C++, but is reduced to a warning to give existing programs a chance to work.

3.1.2.589 W8006: Initializing 'identifier' with 'identifier' (C++)

(Command-line option to suppress warning: `-w-bei`)

You're trying to initialize an `enum` variable to a different type.

For example, the following initialization will result in this warning, because 2 is of type int, not type enum count:

```
enum count zero, one, two x = 2;
```

It is better programming practice to use an enum identifier instead of a literal integer when assigning to or initializing enum types.

This is an error, but is reduced to a warning to give existing programs a chance to work.

3.1.2.590 W8001: Superfluous & with function (C++)

(Command-line option to display warning: -wamp)

An address-of operator (&) is not needed with function name; any such operators are discarded.

3.1.2.591 W8020: 'identifier' is declared as both external and static (C++)

(Command-line option to suppress warning: -w-ext)

This identifier appeared in a declaration that implicitly or explicitly marked it as global or external, and also in a static declaration.

The identifier is taken as static.

You should review all declarations for this identifier.

3.1.2.592 W8007: Hexadecimal value contains more than three digits (C++)

(Command-line option to suppress warning = -w-big)

Under older versions of C, a hexadecimal escape sequence could contain no more than three digits.

The ANSI standard allows any number of digits to appear as long as the value fits in a byte.

This warning results when you have a long hexadecimal escape sequence with many leading zero digits (such as \x00045).

Older versions of C would interpret such a string differently.

3.1.2.593 W8024: Base class 'class1' is also a base class of 'class2' (C++)

(Command-line option to suppress warning: -w-ibc)

A class inherits from the same base class both directly and indirectly. It is best to avoid this non-portable construct in your program code.

3.1.2.594 W8022: 'function1' hides virtual function 'function2' (C++)

(Command-line option to suppress warning: -w-hid)

A virtual function in a base class is usually overridden by a declaration in a derived class.

In this case, a declaration with the same name but different argument types makes the virtual functions inaccessible to further derived classes.

3.1.2.595 W8023: Array variable 'identifier' is near (C++)

(Command-line option to suppress warning: -w-ias)

When you use set the Far Data Threshold option, the compiler automatically makes any global variables that are larger than the threshold size be far.

When the variable is an initialized array with an unspecified size, its total size is not known when the compiler must decide whether to make it near or far, so the compiler makes it near.

The compiler issues this warning if the number of initializers given for the array causes the total variable size to exceed the data size threshold.

If the fact that the compiler made the variable be near causes problems, make the offending variable explicitly far.

To do this, insert the keyword "far" immediately to the left of the variable name in its definition.

3.1.2.596 W8061: Initialization is only partially bracketed (C++)

(Command-line option to display warning: `-wpin`)

When structures are initialized, braces can be used to mark the initialization of each member of the structure. If a member itself is an array or structure, nested pairs of braces can be used. This ensures that the compiler's idea and your idea of what value goes with which member are the same. When some of the optional braces are omitted, the compiler issues this warning.

3.1.2.597 W8038: constant member 'identifier' is not initialized (C++)

(Command-line option to suppress warning: -w-nci)

This C++ class contains a constant member 'member' that doesn't have an initialization.

Note that constant members can be initialized only; they can't be assigned to.

3.1.2.598 W8071: Conversion may lose significant digits (C++)

(Command-line option to display warning: -wsig)

For an assignment operator or some other circumstance, your source file requires a conversion from a larger integral data type to a smaller integral data type where the conversion exists.

Because the integral data type variables don't have the same size, this kind of conversion might alter the behavior of a program.

3.1.2.599 W8043: Macro definition ignored (C++)

(Command-line option to suppress warning: -w-nma)

An error has occurred while using the command-line utility H2ASH. See the online file "tsm_util.txt" for further information about this utility.

3.1.2.600 W8017: Redefinition of 'x' is not identical (C++)

(Command-line option to suppress warning: -w-dup)

Your source file redefined the macro 'ident' using text that was not exactly the same as the first definition of the macro.

The new text replaces the old.

3.1.2.601 W8079: Mixing pointers to different 'char' types (C++)

(Command-line option to display warning: -wucp)

You converted a signed char pointer to an unsigned char pointer, or vice versa, without using an explicit cast. (Strictly speaking, this is incorrect, but it is often harmless.)

3.1.2.602 W8067: Both return and return with a value used (C++)

(Command-line option to suppress warning: -w-ret)

The current function has return statements with and without values.

This is legal C, but almost always generates an error.

Possibly a return statement was omitted from the end of the function.

3.1.2.603 W8048: Use qualified name to access member type 'identifier' (C++)

(Command-line option to suppress warning: -w-nst)

In previous versions of the C++ specification, `typedef` and tag names declared inside classes were directly visible in the global scope.

In the latest specification of C++, these names must be prefixed with class`::`qualifier if they are to be used outside of their class scope.

The compiler issues this warning whenever a name is uniquely defined in a single class. The compiler permits this usage without class`::`. This allows older versions of code to compile.

3.1.2.604 W8039: Constructor initializer list ignored (C++)

(Command-line option to suppress warning: -w-ncl)

An error has occurred while using the command-line utility H2ASH. See the online file "tsm_util.txt" for further information about this utility.

3.1.2.605 W8040: Function body ignored (C++)

(Command-line option to suppress warning: -w-nfd)

An error has occurred while using the command-line utility H2ASH. See the online file "tsm_util.txt" for further information about this utility.

3.1.2.606 W8042: Initializer for object 'x' ignored (C++)

(Command-line option to suppress warning: -w-nin)

An error has occurred while using the command-line utility H2ASH. See the online file "tsm_util.txt" for further information about this utility.

3.1.2.607 W8044: #undef directive ignored (C++)

(Command-line option to suppress warning: -w-nmu)

An error has occurred while using the command-line utility H2ASH. See the online file "tsm_util.txt" for further information about this utility.

3.1.2.608 W8037: Non-const function 'function' called for const object (C++)

(Command-line option to suppress warning = -w-ncf)

A non-const member function was called for a const object.

(This is an error, but was reduced to a warning to give existing programs a chance to work.)

3.1.2.609 W8051: Non-volatile function 'function' called for volatile object (C++)

(Command-line option to suppress warning: -w-nvf)

In C++, a class member function was called for a volatile object of the class type, but the function was not declared with volatile following the function header. Only a volatile member function can be called for a volatile object.

For example, if you have

```
class c
{
public:
  f() volatile;
  g();
};
volatile c vcvar;
```

it is legal to call vcvar.f(), but not to call vcvar.g().

3.1.2.610 W8019: Code has no effect (C++)

(Command-line option to suppress warning: -w-eff)

This warning is issued when the compiler encounters a statement with some operators that have no effect.

For example, the statement

```
a + b;
```

has no effect on either variable.

The operation is unnecessary and probably indicates a bug.

3.1.2.611 W8057: Parameter 'parameter' is never used (C++)

(Command-line option to suppress warning: -w-par)

The named parameter, declared in the function, was never used in the body of the function.

This might or might not be an error and is often caused by misspelling the parameter.

This warning can also occur if the identifier is redeclared as an automatic (local) variable in the body of the function.

The parameter is masked by the automatic variable and remains unused.

3.1.2.612 W8070: Function should return a value (C++)

(Command-line option to suppress warning: `-w-rvl`)

This function was declared (maybe implicitly) to return a value.

The compiler found a return statement without a return value, or it reached the end of the function without finding a return statement.

Either return a value or change the function declaration to return void.

3.1.2.613 W8047: Declaration of static function function ignored (C++)

(Command-line option to suppress warning: -w-nsf)

An error has occurred while using the command-line utility H2ASH. See the online file "tsm_util.txt" for further information about this utility.

3.1.2.614 W8041: Negating unsigned value (C++)

(Command-line option to suppress warning: -w-ngu)

Basically, it makes no sense to negate an unsigned value because the result will still be unsigned.

Example

```
#pragma warn +ngu
unsignedfoo(unsigned u)
{
return-u;
}
```

3.1.2.615 W8054: Style of function definition is now obsolete (C++)

(Command-line option to suppress warning = -w-ofp)

In C++, this old C style of function definition is illegal:

```
int func(p1, p2) int p1, p2; { /* ... */ }
```

This practice might not be allowed by other C++ compilers.

3.1.2.616 W8025: Ill-formed pragma (C++)

(Command-line option to suppress warning: -w-ill)

A pragma does not match one of the pragmas expected by the compiler.

3.1.2.617 W8063: Overloaded prefix operator 'operator' used as a postfix operator (C++)

(Command-line option to suppress warning: -w-pre)

The C++ specification allows you to overload both the prefix and postfix versions of the ++ and -- operators.

Whenever the prefix operator is overloaded, but is used in a postfix context, the compiler uses the prefix operator and issues this warning.

This allows older code to compile.

3.1.2.618 W8015: Declare 'type' prior to use in prototype (C++)

(Command-line option to suppress warning: -w-dpu)

When a function prototype refers to a structure type that has not previously been declared, the declaration inside the prototype is not the same as a declaration outside the prototype.

For example,

```
int func(struct s *ps);  struct s  /* ... */ ;
```

Because there is no "struct s" in scope at the prototype for func, the type of parameter ps is pointer to undefined struct s, and is not the same as the "struct s" that is later declared.

This will result in later warning and error messages about incompatible types, which would be very mysterious without this warning message.

To fix the problem, you can move the declaration for "struct s" ahead of any prototype that references it, or add the incomplete type declaration "struct s;" ahead of any prototype that references "structs".

If the function parameter is a struct, rather than a pointer to struct, the incomplete declaration is not sufficient.

You must then place the struct declaration ahead of the prototype.

3.1.2.619 W8069: Nonportable pointer conversion (C++)

(Command-line option to suppress warning: `-w-rpt`)

A nonzero integral value is used in a context where a pointer is needed or where an integral value is needed; the sizes of the integral type and pointer are the same.

Use an explicit cast if this is what you really meant to do.

3.1.2.620 W8066: Unreachable code (C++)

(Command-line option to suppress warning: -w-rch)

A break, continue, goto, or return statement was not followed by a label or the end of a loop or function.

The compiler checks while, do, and for loops with a constant test condition, and attempts to recognize loops that can't fall through.

3.1.2.621 W8029: Temporary used for parameter '???' (C++)

(Command-line option to suppress warning: -w-lvc)

In C++, a variable or parameter of reference type must be assigned a reference to an object of the same type. If the types do not match, the actual value is assigned to a temporary of the correct type, and the address of the temporary is assigned to the reference variable or parameter.

The warning means that the reference variable or parameter does not refer to what you expect, but to a temporary variable, otherwise unused.

In the following example, function f requires a reference to an int, and c is a char:

```
f(int &amp);
char c;
f(c);
```

Instead of calling f with the address of c, the compiler generates code equivalent to the C++ source code:

```
int X = c, f(X);
```

3.1.2.622 W8031: Temporary used for parameter 'parameter' OR W8029 Temporary used for parameter 'number' OR W8030 Temporary used for parameter 'parameter' in call to 'function' OR W8032 Temporary used for parameter 'number' in call to 'function' (C++)

(Command-line option to suppress warning: -w-lvc)

In C++, a variable or parameter of reference type must be assigned a reference to an object of the same type.

If the types do not match, the actual value is assigned to a temporary of the correct type, and the address of the temporary is assigned to the reference variable or parameter.

The warning means that the reference variable or parameter does not refer to what you expect, but to a temporary variable, otherwise unused.

3.1.2.623 W8032: Temporary used for parameter 2 in call to '???' (C++)

(Command-line option to suppress warning: -w-lvc)

In C++, a variable or parameter of reference type must be assigned a reference to an object of the same type. If the types do not match, the actual value is assigned to a temporary of the correct type, and the address of the temporary is assigned to the reference variable or parameter.

The warning means that the reference variable or parameter does not refer to what you expect, but to a temporary variable, otherwise unused.

In the following example, function f requires a reference to an int, and c is a char:

```
f(int &amp);
char c;
f(c);
```

Instead of calling f with the address of c, the compiler generates code equivalent to the C++ source code:

```
int X = c, f(X);
```

3.1.2.624 W8028: Temporary used to initialize 'identifier' (C++)

(Command-line option to suppress warning: -w-lin)

In C++, a variable or parameter of reference type must be assigned a reference to an object of the same type.

If the types do not match, the actual value is assigned to a temporary of the correct type, and the address of the temporary is assigned to the reference variable or parameter.

The warning means that the reference variable or parameter does not refer to what you expect, but to a temporary variable, otherwise unused.

Example

In this example, function f requires a reference to an int, and c is a char:

```
f(int&);
char c;
f(c);
```

Instead of calling f with the address of c, the compiler generates code equivalent to the C++ source code:

```
int X = c, f(X);
```

3.1.2.625 W8074: Structure passed by value (C++)

(Command-line option to display warning: -wstv)

This warning is generated any time a structure is passed by value as an argument.

It is a frequent programming mistake to leave an address-of operator (&) off a structure when passing it as an argument.

Because structures can be passed by value, this omission is acceptable.

This warning provides a way for the compiler to warn you of this mistake.

3.1.2.626 W8011: Nonportable pointer comparison (C++)

(Command-line option to suppress warning: -w-cpt)

Your source file compared a pointer to a non-pointer other than the constant 0.

You should use a cast to suppress this warning if the comparison is proper.

3.1.2.627 W8075: Suspicious pointer conversion (C++)

(Command-line option to suppress warning: -w-sus)

The compiler encountered some conversion of a pointer that caused the pointer to point to a different type.

You should use a cast to suppress this warning if the conversion is proper.

A common cause of this warning is when the C compiler converts a function pointer of one type to another (the C++ compiler generates an error when asked to do that). It can be suppressed by doing a typecast. Here is a common occurrence of it for Windows programmers:

```
#define STRICT
#include <windows.h>
LPARAM _export WndProc( HWND , UINT , WPARAM , LPARAM );
test() {
   WNDCLASS wc;
   wc.lpfnWndProc = WndProc;  //warning
}
```

It is suppressed by making the assignment to lpfnWndProc as follows:

```
wc.lpfnWndProc = ( WNDPROC ) WndProc;
```

3.1.2.628 W8059: Structure packing size has changed (C++)

(Command-line option to suppress warning: -w-pck)

This warning message is issued when the structure alignment is different after including a file than it was before including that file.

The intention is to warn you about cases where an include file changes structure packing, but by mistake doesn't restore the original setting at the end. If this is intentional, you can give a #pragma nopackwarning directive at the end of an include file to disable the warning for this file.

The warning can be disabled altogether by #pragma warn -pck.

3.1.2.629 W8045: No declaration for function 'function' (C++)

(Command-line option to display warning: -wnod)

This message is given if you call a function without first declaring that function.

In C, you can declare a function without presenting a prototype, as in

```
int func();
```

In C++, every function declaration is also a prototype; this example is equivalent to

```
int func(void);
```

The declaration can be either classic or modern (prototype) style.

3.1.2.630 W8073: Undefined structure 'structure' (C++)

(Command-line option to display warning = `-wstu`)

Your source file used the named structure on some line before where the error is indicated (probably on a pointer to a structure) but had no definition for the structure.

This is probably caused by a misspelled structure name or a missing declaration.

3.1.2.631 W8013: Possible use of 'identifier' before definition (C++)

(Command-line option to display warning: -wdef)

Your source file used the variable 'identifier' in an expression before it was assigned a value.

The compiler uses a simple scan of the program to determine this condition.

If the use of a variable occurs physically before any assignment, this warning will be generated.

Of course, the actual flow of the program can assign the value before the program uses it.

3.1.2.632 W8004: 'identifier' is assigned a value that is never used (C++)

(Command-line option to suppress warning: -w-aus)

The variable appears in an assignment, but is never used anywhere else in the function just ending.

The warning is indicated only when the compiler encounters the closing brace.

The `#pragma warn -aus` switch has function-level granularity. You cannot turn off this warning for individual variables within a function; it is either off or on for the whole function.

3.1.2.633 W8081: Void functions may not return a value (C++)

(Command-line option to suppress warning: -w-voi)

Your source file declared the current function as returning void, but the compiler encountered a return statement with a value. The value of the return statement will be ignored.

Example

```
// This HAS to be in a "C" file.  In a "C++" file this would be an error
void foo()
{
        return 0;       // Can't return a value from a void function
}
```

3.1.2.634 W8078: Throw expression violates exception specification (C++)

(Command-line option to suppress warning: -w-thr)

This warning happens when you add an exception specification to a function definition and you throw a type in your function body that is not mentioned in your exception specification.

The following program would generate this warning:

```
int foo() throw(char*)  // I promise to only throw char*s
{
    throw 5;  // Oops, I threw an integer
    return 0;
}
```

3.1.2.635 W8021: Handler for 'type1' hidden by previous handler for 'type2' (C++)

(Command-line option to suppress warning: -w-hch)

This warning is issued when a handler for a type 'D' that is derived from type 'B' is specified after a handler for B', since the handler for 'D' will never be invoked.

3.1.2.636 W8056: Integer arithmetic overflow (C++)

The compiler detected an overflow condition in an integer math expression.

For example:

```
int X = 0xFFFF * 0xFFFF;
```

3.1.2.637 W8035: User-defined message (C++)

The error message for which you have requested Help is a user-defined warning.

In C++ code, user-defined messages are introduced by using the `#pragma` message compiler syntax.

`Note:` In addition to messages that you introduce with the `#pragma` message compiler syntax, user-defined warnings can be introduced by third party libraries. Should you require Help about a third party warning, please contact the vendor of the header file that issued the warning.

3.1.2.638 W8049: Use '> >' for nested templates Instead of '>>' (C++)

(Command-line option to suppress warning: -w-ntd)

Whitespace is required to separate the closing ">" in a nested template name, but since it is an extremely common mistake to leave out the space, the compiler accepts a ">>" with this warning.

3.1.2.639 W8026: Functions with exception specifications are not expanded inline (C++)

Also:Functions taking class by value arguments are not expanded inline

(Command-line option to suppress warning: -w-inl)

Exception specifications are not expanded inline: Check your inline code for lines containing exception specification.

Functions taking class-by-value argument(s) are not expanded inline: When exception handling is enabled, functions that take class arguments by value cannot be expanded inline.

`Note:` Functions taking class parameters by reference are not subject to this restriction.

3.1.2.640 W8058: Cannot create pre-compiled header: 'reason' (C++)

(Command-line option to suppress warning: -w-pch)

This warning is issued when pre-compiled headers are enabled but the compiler could not generate one, for one of the following reasons:

ReasonExplanation

write failedThe compiler could not write to the pre-compiled header file. This occurs if you specified an invalid location to cache precompiled headers or if the disk is full.

code in headerOne of the headers contained a non-inline function body.

initialized data in headerOne of the headers contained a global variable definition (in C, a global variable with an initializer; in C++ any variable not declared as 'extern').

header incompleteThe pre-compiled header ended in the middle of a declaration, for example, inside a class definition (this often happens when there is a missing closing brace in a header file).

3.1.2.641 W8046: Pragma option pop with no matching option push (C++)

The compiler encountered a #pragma option pop before a previous #pragma option push, or in the case of nesting, there are more occurrences of #pragma option pop than of #pragma option push.

3.1.2.642 W8050: No type OBJ file present; disabling external types option. (C++)

(Command-line option to suppress warning: -w-nto)

A precompiled header file references a type object file, but the type object file cannot be found. This is not a fatal problem but will make your object files larger than necessary.

3.1.2.643 W8027: Functions containing 'statement' are not expanded inline (C++)

(Command-line option to suppress warning: -w-inl)

Where:

'statement' can be any of the following:

- Static variables
- Aggregate initializers
- Some return statements
- Local destructors
- Some if statements
- Local classes
- Missing return statements
- Disallowed reserved words listed under "Reserved words" below.

Reserved words

Functions containing any of these reserved words can't be expanded inline, even when specified as inline:

asm	except
break	finally
case	for
continue	goto
defaults	switch
do	while

The function is still perfectly legal, but will be treated as an ordinary static (not global) function.

A copy of the function will appear in each compilation unit where it is called.

Description

If an inline function becomes too complex, the compiler is unable to expand it inline. However, because the function is so complex, expanding it inline is unlikely to provide significant performance enhancements.

For local destructors

You've created an inline function for which the compiler turns off inlining. You can ignore this warning; the function will be generated out of line.

3.1.2.644 W8036: Non-ANSI keyword used: 'keyword' (C++)

(Command-line option to display warning: -wnak)

A non-ANSI keyword (such as '__fastcall') was used when strict ANSI conformance was requested via the -A option.

3.1.2.645 W8053: 'ident' is obsolete (C++)

(Command-line option to suppress warning: -w-obs)

Issues a warning upon usage for any "C" linkage function that has been specified. This will warn about functions that are "obsolete".

Here's an example of it's usage:

```
#ifdef __cplusplus
extern "C" {
#endif
void my_func(void);
#ifdef __cplusplus
}
#endif
#pragma obsolete my_func
main()
{
my_func();   // Generates warning about obsolete function
}
```

3.1.2.646 W8103: Path 'path' and filename 'filename' exceed maximum size of 'n' (C++)

(Command-line option to display warning: -wstv)

In looking up include files, the C++ compiler has encountered a file whose path and filename contain more characters than are allowed in the Windows maximum. Rename the paths and filenames that you can, and shorten their names wherever possible.

3.1.2.647 W8062: Previous options and warnings not restored (C++)

The compiler didn't encounter a #pragma option pop after a previous #pragma option push, or in the case of nesting, there are more occurrences of #pragma option push than of #pragma option pop.

3.1.2.648 W8055: Possible overflow in shift operation (C++)

The compiler detects cases where the number of bits shifted over is larger than the number of bits in the affected variable; for example:

```
char c;  c >> 16;
```

3.1.2.649 W8072: Suspicious pointer arithmetic (C++)

This message indicates an unintended side effect to the pointer arithmetic (or array indexing) found in an expression.

Example

```
#pragma warn +spa
intarray[10];
intfoo(__int64 index)
{
returnarray[index];
}
```

The value of index is 64 bits wide while the address of array is only 32 bits wide.

3.1.2.650 W8033: Conversion to 'type' will fail for members of virtual base 'class' (C++)

(Command-line option to suppress warning: -w-mpc)

This warning is issued only if the `-Vv` option is in use.

The warning may be issued when a member pointer to one type is cast to a member pointer of another type and the class of the converted member pointer has virtual bases.

Encountering this warning means that at runtime, if the member pointer conversion cannot be completed, the result of the cast will be a NULL member pointer.

3.1.2.651 W8034: Maximum precision used for member pointer type 'type' (C++)

(Command-line option to suppress warning: -w-mpd)

When a member pointer type is declared, its class has not been fully defined, and the `-Vmd` option has been used, the compiler has to use the most general (and the least efficient) representation for that member pointer type. This can cause less efficient code to be generated (and make the member pointer type unnecessarily large), and can also cause problems with separate compilation; see the `-Vm` compiler switch for details.

3.1.2.652 E2537: Cannot create instance of abstract class (C++)

This class is an abstract class, which you cannot instantiate.

3.1.2.653 E2018: Cannot catch 'identifier' -- ambiguous base class 'identifier' (C++)

It is not legal to catch a class that contains more than one copy of a (non-virtual) base class. However, you can catch the exception as a more derived type. For example:

```
struct awkward : std::runtime_error, std::logic_error {};

 try {
 }
 catch( std::exception & ) { // ambiguous, not caught here
 }
 catch( std::runtime_error & ) { // caught here
 }
```

Note that the compiler might warn you that the second catch cannot be triggered because the first clause should catch all matching exceptions. But the ambiguous base case is caught by the second clause.

3.1.2.654 E2550: No arguments can follow a variadic template in an argument list (C++)

In an argument list, the variadic template must not be followed by arguments.

3.1.2.655 E2538: Static assert failed: '%s' (C++)

See Static Assertions (see page 498) for details about how to use static_assert., which is one of the C++0x features.

3.1.2.656 E2548: ... was unexpected; expression is not a variadic template pattern (C++)

This message pertains to the expected syntax of variadic templates.

3.1.2.657 E2543: Combination of options 'options' is not permitted (C++)

Eliminate the combination of options.

For example, you cannot combine the C++ compiler options -b- and -bi because -b- turns off all -b options, including -bi.

3.1.2.658 E2549: Operand is not a parameter pack (C++)

A parameter pack is required in the indicated location. This message pertains to variadic templates.

3.1.2.659 E2544: Function exception specifications do not match (C++)

The throw specifications on two function declaration/definitions which refer to the same function do not agree. Rewrite the function exception specifications to match.

3.1.2.660 E2536: Incomplete type cannot be part of a exception declaration (C++)

This error occurs when an incomplete type is used in exception declaration. From C++ ISO 14882:1998 15.3.1: "The exception-declaration shall not denote an incomplete type. The exception-declaration shall not denote a pointer or reference to an incomplete type, other than void*, const void*, volatile void*, or const volatile void*. Types shall not be defined in an exception-declaration.

3.1.2.661 E2535: Incomplete type cannot be part of a throw specification (C++)

This error occurs when an incomplete type is used in a throw specification. From C++ ISO 14882:1998 15.1.3: "The type of the throw-expression shall not be an incomplete type, or a pointer or reference to an incomplete type, other than void*, const void*, volatile void*, or const volatile void*." This includes exception specifications (15.4.1).

3.1.2.662 E2532: Constant in new expression requires an initializer (C++)

If the type is const then either an initializer must be present or the non-POD class must have a user-declared constructor. Error in ANSI mode, warning if ANSI mode is not set.

3.1.2.663 E2541: Attribute '%s' cannot be set (C++)

This error occurs if the specified attribute cannot be applied to this entity.

3.1.2.664 E2545: Enum underlying type must be an integral (C++)

Ensure that the underlying type of the enumeration is an integral type.

The underlying type of a scoped enum is fixed to int unless explicitly provided by the user. The underlying type of a 'classic' enum remains unspecified unless fixed by the user.

For more information, see Strongly Typed Enums (see page 498).

3.1.2.665 E2546: Redeclaration of enum is not identical (C++)

This error occurs if:

- a re-declaration of an enum has a different underlying type
- a scoped enum is re-declared as an unscoped enum
- an unscoped enum is re-declared as a scoped enum

For more information, see Strongly Typed Enums (see page 498).

3.1.2.666 E2533: Parameter mismatch (wanted typename) (C++)

This error occurs when a parameter passed to a type trait function is not the correct type.

3.1.2.667 E2534: Integral constant expression expected (C++)

Integral constant expressions are described in section 5.19 of the C++ standard, and are sometimes referred to as "compile time constants". A working draft for the C++ standard can be found at

http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2008/n2588.pdf.

3.1.2.668 E2531: Parameter is an incomplete type (C++)

This error occurs when an incomplete type is passed into a type trait function that does not accept incomplete type parameters. For example:

```
class A;
void foo()
{
  __is_abstract(A); // error
}
```

3.1.2.669 E2539: Constant expression expected (C++)

You need to supply a constant expression in the indicated location.

For details about using a constant expression in a static assertion, see Static Assertions (see page 498).

3.1.2.670 E2547: ... expected (C++)

An ellipsis (...) is expected in the location indicated.

3.1.2.671 E2540: String literal expected (C++)

You need to specify a string literal in the position indicated in the error message.

A string literal is the second argument in a static assertion. For details about using a static assertion, see Static Assertions (see page 498).

3.1.2.672 E2552: This feature is not (yet) supported (C++)

Support might be added in a coming release.

3.1.2.673 E2542: '%s' is marked 'final' and cannot be overriden (C++)

The attribute 'final' applies to class definitions and to virtual member functions being declared in a class definition. If the attribute is specified for a class definition, it is equivalent to being specified for each virtual member function of that class, including inherited member functions. If a virtual member function f in some class B is marked 'final' and in a class D derived from B, a function D::f overrides B::f, the program is ill-formed.

3.1.2.674 E2553: %s mismatch in redeclaration of '%s' (C++)

Attributes specified on a declaration have to be a subset of attributes specified on a definition.

3.1.2.675 E2551: Return statement not allowed in __finally block (C++)

Rewrite the `__finally` block so that it does not contain a return statement.

For more information, see Writing a finally Block in C++ (see page 2023) and finally keyword (see page 550).

3.1.2.676 W8104: Local Static with constructor dangerous for multi-threaded apps (C++)

(Command-line option to suppress warning: -w-mls)

This warning is generated for local static objects with constructors for multithreaded programs. This situation can cause problems if two threads enter the containing function at the same time and no critical sections are present, allowing the constructor to potentially be called more than once.

3.1.2.677 W8106: %s are deprecated (C++)

You have used an old style syntax or language use that is deprecated -- that is, no longer recommended and might be phased out in the future.

3.1.2.678 W8110: Duplicate '%s' attribute directive ignored (C++)

(Command-line option to suppress warning: -w-dat)

This warning is generated if the same attribute was specified more than once for the same entity.

3.1.2.679 W8108: Constant in new expression requires an initializer (C++)

(Command-line option to suppress warning: -w-nci)

If the type is const then either an initializer must be present or the non-POD class must have a user-declared constructor. Error in ANSI mode, warning if ANSI mode is not set.

3.1.2.680 W8113: Inline function was declared with 'extern template' (C++)

(Command-line option to suppress warning: -w-iex)

'extern template' has no normative effect on inline functions. Implementations are encouraged to suppress out-of-line copies of inline functions that were declared with 'extern template'.

3.1.2.681 W8109: Parameter '%s' is a dependent type (C++)

(Command-line option to enable warning: -wpad)

This warning is generated if a parameter of an intrinsic function is a dependent type and the dependency cannot be resolved.

3.1.2.682 W8105: Reference/Constant member 'identifier' in class without constructors (C++)

(Command-line option to suppress warning: -w-mnc)

This warning is generated for a reference or constant member in a class without constructors if ANSI mode is not set. In ANSI mode this is an error.

3.1.2.683 W8107: Type name expected (C++)

(Command-line option to enable warning: -wntn)

This warning is generated if the type of a class/union member is omitted in its declaration and ANSI mode is not set. Always an error in ANSI mode.

3.1.2.684 W8112: Unresolved dependencies in expression (C++)

(Command-line option to suppress warning: -w-dex)

This warning is generated if dependencies in the expression cannot be resolved.

3.1.3 C++ Language Guide

3.1.3.1.1 Classes

This section contains Class topics.

Topics

Name	Description
C++ Classes (see page 387)	C++ classes offer extensions to the predefined type system. Each class type represents a unique set of objects and the operations (methods) and conversions available to create, manipulate, and destroy such objects. Derived classes can be declared that inherit the members of one or more base (or parent) classes. In C++, structures and unions are considered classes with certain access defaults. A simplified, “first-look” syntax for class declarations is class-key <type-info> class-name <: base-list> { <member-list> }; class-key is one of **class**, **struct**, or **union**. The optional type-info indicates a request for runtime type information about the... more (see page 387)
Friends Of Classes (see page 388)	This section contains Friends Of Class topics.

Class Member List (see page 390)	The optional member-list is a sequence including, but not exclusive to: • Data declarations (of any type, including enumerations, bit fields and other classes) • Nested type declarations • Nested type definitions • Template declarations • Template definitions • Function declarations • Function definitions • Constructors • A destructor Members of a class can optional have storage class specifiers and access modifiers. The objects thus defined are called class members. The storage class specifiers **auto**, **extern**, and **register** are not allowed. Members can be declared with the **static** storage class specifiers.
Inline Functions (see page 391)	This section contains Inline Function topics.
Class Name Scope (see page 393)	The scope of a class name is local. There are some special requirements if the class name appears more than once in the same scope. Class name scope starts at the point of declaration and ends with the enclosing block. A class name hides any class, object, enumerator, or function with the same name in the enclosing scope. If a class name is declared in a scope containing the declaration of an object, function, or enumerator of the same name, the class can be referred to only by using the elaborated type specifier. This means that the class key, **class... more (see page 393)**
The Keyword This (see page 394)	This section contains Keyword this topics.
Class Names (see page 396)	**class-name** is any identifier unique within its scope. With structures, classes, and unions, class-name can be omitted. See Untagged structures and typedefs for discussion of untagged structures.
Member Scope (see page 396)	This section contains Member Scope topics.
Class Objects (see page 402)	Class objects can be assigned (unless copying has been restricted), passed as arguments to functions, returned by functions (with some exceptions), and so on. Other operations on class objects and members can be user-defined in many ways, including definition of member and friend functions and the redefinition of standard functions and operators when used with objects of a certain class. Redefined functions and operators are said to be overloaded. Operators and functions that are restricted to objects of a certain class (or related group of classes) are called member functions for that class. C++ offers the overloading mechanism that allows... more (see page 402)
Virtual Base Classes (see page 403)	This section contains Virtual Base Class topics.
Class Types (see page 404)	The declaration creates a unique type, class type class-name. This lets you declare further class objects (or instances) of this type, and objects derived from this type (such as pointers to, references to, arrays of class-name, and so on):
Member Functions (see page 405)	A function declared without the **friend** specifier is known as a member function of the class. Functions declared with the **friend** modifier are called friend functions. Member functions are often referred to as methods in Delphi documentation. The same name can be used to denote more than one function, provided they differ in argument type or number of arguments.
VCL Class Declarations (see page 405)	**Syntax**
Class Methods (see page 406)	In C++Builder, a **class method** is a method that can be invoked on a class name, as well as on an instance of that class. In contrast, object methods can be invoked only on objects -- instances of a class.
Static Properties (see page 410)	Static properties have been implemented in C++Builder 2009 to enhance compatibility with the Delphi language

3.1.3.1.1.1 C++ Classes

C++ classes offer extensions to the predefined type system. Each class type represents a unique set of objects and the

operations (methods) and conversions available to create, manipulate, and destroy such objects. Derived classes can be declared that inherit the members of one or more base (or parent) classes.

In C++, structures and unions are considered classes with certain access defaults.

A simplified, “first-look” syntax for class declarations is

class-key <type-info> class-name

<: base-list> { <member-list> };

class-key is one of **class**, **struct**, or **union**.

The optional type-info indicates a request for runtime type information about the class. You can compile with the **–RT** compiler option, or you can use the **__rtti** keyword.

The optional base-list lists the base class or classes from which the class class-name will derive (or inherit) objects and methods. If any base classes are specified, the class class-name is called a derived class. The base-list has default and optional overriding access specifiers that can modify the access rights of the derived class to members of the base classes.

The optional member-list declares the class members (data and functions) of class-name with default and optional overriding access specifiers that can affect which functions can access which members.

3.1.3.1.1.2 Friends Of Classes

This section contains Friends Of Class topics.

Topics

Name	Description
Friends Of Classes (see page 389)	A **friend** F of a class X is a function or class, although not a member function of X, with full access rights to the private and protected members of X. In all other respects, F is a normal function with respect to scope, declarations, and definitions. Since F is not a member of X, it is not in the scope of X, and it cannot be called with the x.F and xptr->F selector operators (where x is an X object and xptr is a pointer to an X object). If the specifier **friend** is used with a function declaration... more (see page 389)

3.1.3.1.1.2.1 Friends Of Classes

A **friend** F of a class X is a function or class, although not a member function of X, with full access rights to the private and protected members of X. In all other respects, F is a normal function with respect to scope, declarations, and definitions.

Since F is not a member of X, it is not in the scope of X, and it cannot be called with the x.F and xptr->F selector operators (where x is an X object and xptr is a pointer to an X object).

If the specifier **friend** is used with a function declaration or definition within the class X, it becomes a friend of X.

friend functions defined within a class obey the same inline rules as member functions (see Inline functions). **friend** functions are not affected by their position within the class or by any access specifiers. For example:

```
class X {
   int i;                           // private to X
   friend void friend_func(X*, int);
/* friend_func is not private, even though it's declared in the private section */
public:
     void member_func(int);
};
/* definitions; note both functions access private int i */
void friend_func(X* xptr, int a) { xptr->i = a; }
void X::member_func(int a) { i = a; }
X xobj;
/* note difference in function calls */
friend_func(&xobj, 6);
xobj.member_func(6);
```

You can make all the functions of class Y into friends of class X with a single declaration:

```
class Y;                        // incomplete declaration
class X {
   friend Y;
   int i;
   void member_funcX();
};
class Y; {                      // complete the declaration
   void friend_X1(X&);
   void friend_X2(X*);
.
.
.
};
```

The functions declared in Y are friends of X, although they have no **friend** specifiers. They can access the private members of X, such as i and member_funcX.

It is also possible for an individual member function of class X to be a friend of class Y:

```
class X {
.
.
.
   void member_funcX();
```

```
}
class Y {
   int i;
   friend void X::member_funcX();
.
.
.
};
```

Class friendship is not transitive: X friend of Y and Y friend of Z does not imply X friend of Z. Friendship is not inherited.

3.1.3.1.1.3 Class Member List

The optional member-list is a sequence including, but not exclusive to:

- Data declarations (of any type, including enumerations, bit fields and other classes)
- Nested type declarations
- Nested type definitions
- Template declarations
- Template definitions
- Function declarations
- Function definitions
- Constructors
- A destructor

Members of a class can optional have storage class specifiers and access modifiers. The objects thus defined are called class members. The storage class specifiers **auto**, **extern**, and **register** are not allowed. Members can be declared with the **static** storage class specifiers.

3.1.3.1.1.4 Inline Functions

This section contains Inline Function topics.

Topics

Name	Description
Inline Functions (see page 391)	You can declare a member function within its class and define it elsewhere. Alternatively, you can both declare and define a member function within its class, in which case it is called an inline function. The compiler can sometimes reduce the normal function call overhead by substituting the function call directly with the compiled code of the function body. This process, called an inline expansion of the function body, does not affect the scope of the function name or its arguments. Inline expansion is not always possible or feasible. The **inline** specifier indicates to the compiler you would like an... more (see page 391)

3.1.3.1.1.4.1 Inline Functions

You can declare a member function within its class and define it elsewhere. Alternatively, you can both declare and define a member function within its class, in which case it is called an inline function.

The compiler can sometimes reduce the normal function call overhead by substituting the function call directly with the compiled code of the function body. This process, called an inline expansion of the function body, does not affect the scope of the function name or its arguments. Inline expansion is not always possible or feasible. The **inline** specifier indicates to the compiler you would like an inline expansion.

Note: The compiler can ignore requests for inline expansion.

Explicit and implicit **inline** requests are best reserved for small, frequently used functions, such as the operator functions that implement overloaded operators. For example, the following class declaration of func:

```
int i;                          // global int
class X {
public:
```

```
   char* func(void) { return i; }  // inline by default
   char* i;
};
```

is equivalent to:

```
inline char* X::func(void) { return i; }
```

func is defined outside the class with an explicit **inline** specifier. The value i returned by func is the **char*** i of class X (see Member scope).

Inline functions and exceptions

An inline function with an exception-specification will never be expanded inline by the compiler. For example,

```
inline void f1() throw(int)
{
   // Warning: Functions with exception specifications are not expanded inline
}
```

The remaining restrictions apply only when destructor cleanup is enabled.

Note: Destructors are called by default. See Setting exception handling options for information about exception-handling switches.

An inline function that takes at least one parameter that is of type 'class with a destructor' will not be expanded inline. Note that this restriction does not apply to classes that are passed by reference. Example:

```
struct foo {
   foo();
   ~foo();
};
inline void f2(foo& x)
{
   // no warning, f2() can be expanded inline
}
inline void f3(foo x)
{
   // Warning: Functions taking class-by-value argument(s) are
   //          not expanded inline in function f3(foo)
}
```

An inline function that returns a class with a destructor by value will not be expanded inline whenever there are variables or temporaries that need to be destructed within the return expression:

```
struct foo {
   foo();
   ~foo();
};
inline foo f4()
{
   return foo();
   // no warning, f4() can be expanded inline
}
inline foo f5()
{
   foo X;
   return foo(); // Object X needs to be destructed
   // Warning: Functions containing some return statements are
   //          not expanded inline in function f5()
}
inline foo f6()
{
   return ( foo(), foo() );  // temporary in return value
   // Warning:Functions containing some return statements are
   //         not expanded inline in function f6()
}
```

3.1.3.1.1.5 Class Name Scope

The scope of a class name is local. There are some special requirements if the class name appears more than once in the same scope. Class name scope starts at the point of declaration and ends with the enclosing block. A class name hides any class, object, enumerator, or function with the same name in the enclosing scope. If a class name is declared in a scope containing the declaration of an object, function, or enumerator of the same name, the class can be referred to only by using the elaborated type specifier. This means that the class key, **class**, **struct**, or **union**, must be used with the class name. For example,

```
struct S { ... };
int S(struct S *Sptr);
void func(void) {
   S t;         // ILLEGAL declaration: no class key and function S in scope
   struct S s;  // OK: elaborated with class key
   S(&s);       // OK: this is a function call
}
```

C++ also allows a forward class declaration:

```
class X;  // no members, yet!
```

Forward declarations permit certain references to class name X (usually references to pointers to class objects) before the class has been fully defined. See Structure member declarations for more information. Of course, you must make a complete class declaration with members before you can define and use objects of that class.

See also the syntax for forward declarations of VCL classes.

3.1.3.1.1.6 The Keyword This

This section contains Keyword this topics.

Topics

Name	Description
Static Members (see page 394)	The storage class specifier **static** can be used in class declarations of data and function members. Such members are called static members and have distinct properties from nonstatic members. With nonstatic members, a distinct copy “exists” for each instance of the class; with static members, only one copy exists, and it can be accessed without reference to any particular object in its class. If x is a static member of class X, it can be referenced as X::x (even if objects of class X haven’t been created yet). It is still possible to access x using the normal member access... more (see page 394)

3.1.3.1.1.6.1 Static Members

The storage class specifier **static** can be used in class declarations of data and function members. Such members are called static members and have distinct properties from nonstatic members. With nonstatic members, a distinct copy “exists” for each instance of the class; with static members, only one copy exists, and it can be accessed without reference to any particular object in its class. If x is a static member of class X, it can be referenced as X::x (even if objects of class X haven’t been created yet). It is still possible to access x using the normal member access operators. For example, y.x and yptr->x, where y is an object of class X and yptr is a pointer to an object of class X, although the expressions y and yptr are not evaluated. In particular, a static member function can be called with or without the special member function syntax:

```
class X {
   int member_int;
public:
   static void func(int i, X* ptr);
};
void g(void)
{
   X obj;
   func(1, &obj);       // error unless there is a global func()
                        // defined elsewhere
   X::func(1, &obj);    // calls the static func() in X
                        // OK for static functions only
   obj.func(1, &obj);   // so does this (OK for static and
                        // nonstatic functions)
}
```

Because static member functions can be called with no particular object in mind, they don’t have a **this** pointer, and therefore

cannot access nonstatic members without explicitly specifying an object with **.** or **->**. For example, with the declarations of the previous example, func might be defined as follows:

```
void X::func(int i, X* ptr)
{
   member_int = i;       // which object does member_int
                         // refer to? Error
   ptr->member_int = i;  // OK: now we know!
}
```

Apart from inline functions, static member functions of global classes have external linkage. Static member functions cannot be virtual functions. It is illegal to have a static and nonstatic member function with the same name and argument types.

The declaration of a static data member in its class declaration is not a definition, so a definition must be provided elsewhere to allocate storage and provide initialization.

Static members of a class declared local to some function have no linkage and cannot be initialized. Static members of a global class can be initialized like ordinary global objects, but only in file scope. Static members, nested to any level, obey the usual class member access rules, except they can be initialized.

```
class X {
   static int x;
   static const int size =  5;
   class inner {
      static float f;
      void func(void);     // nested declaration
      };
public :
   char array[size];
};
int X::x = 1;
float X::inner::f = 3.14;  // initialization of nested static
void X::inner::func(void) {     /*  define the nested function */  }
```

The principal use for static members is to keep track of data common to all objects of a class, such as the number of objects created, or the last-used resource from a pool shared by all such objects. Static members are also used to

- Reduce the number of visible global names
- Make obvious which static objects logically belong to which class
- Permit access control to their names

3.1.3.1.1.8 Member Scope

This section contains Member Scope topics.

Topics

Name	Description
Base And Derived Class Access (see page 397)	When you declare a derived class D, you list the base classes B1, B2, ... in a comma-delimited base-list:
Member Access Control (see page 399)	Members of a class acquire access attributes either by default (depending on class key and declaration placement) or by the use of one of the three access specifiers: **public**, **private**, and **protected**. The significance of these attributes is as follows: • **public**: The member can be used by any function. • **private**: The member can be used only by member functions and friends of the class it's declared in. • **protected**: Same as for **private**. Additionally, the member can be used by member functions and friends of classes derived from the declared class, but only in... more (see page 399)

Member Scope (see page 400)	The expression X::func() in the example in Inline functions and exceptions uses the class name X with the scope access modifier to signify that func, although defined “outside” the class, is indeed a member function of X and exists within the scope of X. The influence of X:: extends into the body of the definition. This explains why the i returned by func refers to X::i, the **char*** i of X, rather than the global **int** i. Without the X:: modifier, the function func would represent an ordinary non-class function, returning the global **int** i. All member functions, then,... more (see page 400)
Nested Types (see page 401)	Tag or **typedef** names declared inside a class lexically belong to the scope of that class. Such names can, in general, be accessed only by using the **xxx::yyy** notation, except when in the scope of the appropriate class. A class declared within another class is called a nested class. Its name is local to the enclosing class; the nested class is in the scope of the enclosing class. This is a purely lexical nesting. The nested class has no additional privileges in accessing members of the enclosing class (and vice versa). Classes can be nested in this way to... more (see page 401)

3.1.3.1.1.8.1 Base And Derived Class Access

When you declare a derived class D, you list the base classes B1, B2, ... in a comma-delimited base-list:

```
class-key D : base-list { <member-list> }
```

D inherits all the members of these base classes. (Redefined base class members are inherited and can be accessed using scope overrides, if needed.) D can use only the **public** and **protected** members of its base classes. But, what will be the access attributes of the inherited members as viewed by D? D might want to use a **public** member from a base class, but make it **private** as far as outside functions are concerned. The solution is to use access specifiers in the base-list.

Note: Since a base class can itself be a derived class, the access attribute question is recursive: you backtrack until you reach the basemost of the base classes, those that do not inherit.

When declaring D, you can use the access specifier **public**, **protected**, or **private** in front of the classes in the base-list:

```
class D : public B1, private B2, ... {
   .
   .
   .
}
```

These modifiers do not alter the access attributes of base members as viewed by the base class, though they can alter the access attributes of base members as viewed by the derived class.

The default is private if D is a class declaration, and public if D is a struct declaration.

Note: Unions cannot have base classes, and unions cannot be used as base classes.

The derived class inherits access attributes from a base class as follows:

- **public** base class: **public** members of the base class are **public** members of the derived class. **protected** members of the base class are **protected** members of the derived class. **private** members of the base class remain **private** to the base class.
- **protected** base class: Both **public** and **protected** members of the base class are **protected** members of the derived class. **private** members of the base class remain **private** to the base class.
- **private** base class: Both **public** and **protected** members of the base class are **private** members of the derived class. **private** members of the base class remain **private** to the base class.

Note that **private** members of a base class are always inaccessible to member functions of the derived class unless **friend** declarations are explicitly declared in the base class granting access. For example,

```
/* class X is derived from class A */
class X : A {               // default for class is private A
   .
   .
   .
}
/* class Y is derived (multiple inheritance) from B and C
```

```
   B defaults to private B */
class Y : B, public C {     // override default for C
  .
  .
  .
}
/* struct S is derived from D */
struct S : D {              // default for struct is public D
  .
  .
  .
}
/* struct T is derived (multiple inheritance) from D and E
   E defaults to public E */
struct T : private D, E {   // override default for D
                            // E is public by default
  .
  .
  .
}
```

The effect of access specifiers in the base list can be adjusted by using a qualified-name in the public or protected declarations of the derived class. For example:

```
class B {
   int a;               // private by default
public:
   int b, c;
   int Bfunc(void);
};
class X : private B {   // a, b, c, Bfunc are now private in X
   int d;               // private by default, NOTE: a is not
                        // accessible in X
public:
   B::c;                // c was private, now is public
   int e;
   int Xfunc(void);
};
int Efunc(X& x);        // external to B and X
```

The function Efunc() can use only the public names c, e, and Xfunc().

The function Xfunc() is in X, which is derived from **private** B, so it has access to

- The “adjusted-to-public” c
- The “private-to-X” members from B: b and Bfunc()
- X’s own private and public members: d, e, and Xfunc()

However, Xfunc() cannot access the “private-to-B” member, a.

3.1.3.1.1.8.2 Member Access Control

Members of a class acquire access attributes either by default (depending on class key and declaration placement) or by the use of one of the three access specifiers: **public**, **private**, and **protected**. The significance of these attributes is as follows:

- **public**: The member can be used by any function.
- **private**: The member can be used only by member functions and friends of the class it's declared in.
- **protected**: Same as for **private**. Additionally, the member can be used by member functions and friends of classes derived from the declared class, but only in objects of the derived type. (Derived classes are explained in Base and derived class access.)

  Note: Friend function declarations are not affected by access specifiers (see Friends of classes for more information).

  Members of a class are **private** by default, so you need explicit **public** or **protected** access specifiers to override the default.

  Members of a **struct** are **public** by default, but you can override this with the **private** or **protected** access specifier.

  Members of a **union** are **public** by default; this cannot be changed. All three access specifiers are illegal with union members.

  A default or overriding access modifier remains effective for all subsequent member declarations until a different access modifier is encountered. For example,

```
class X {
   int i;    // X::i is private by default
   char ch;  // so is X::ch
public:
   int j;    // next two are public
   int k;
protected:
   int l;    // X::l is protected
};
struct Y {
   int i;    // Y::i is public by default
private:
   int j;    // Y::j is private
public:
   int k;    // Y::k is public
};
union Z {
   int i;    // public by default; no other choice
   double d;
};
```

Note: The access specifiers can be listed and grouped in any convenient sequence. You can save typing effort by declaring all the private members together, and so on.

3.1.3.1.1.8.3 Member Scope

The expression X::func() in the example in Inline functions and exceptions uses the class name X with the scope access modifier to signify that func, although defined “outside” the class, is indeed a member function of X and exists within the scope of X. The influence of X:: extends into the body of the definition. This explains why the i returned by func refers to X::i, the **char*** i of X, rather than the global **int** i. Without the X:: modifier, the function func would represent an ordinary non-class function, returning the global **int** i.

All member functions, then, are in the scope of their class, even if defined outside the class.

Data members of class X can be referenced using the selection operators **.** and **->** (as with C structures). Member functions can also be called using the selection operators (see The keyword this). For example:

```
class X {
public:
   int i;
   char name[20];
   X *ptr1;
   X *ptr2;
   void Xfunc(char*data, X* left, X* right);   // define elsewhere
};
void f(void);
{
   X x1, x2, *xptr=&x1;
   x1.i = 0;
   x2.i = x1.i;
   xptr->i = 1;
   x1.Xfunc("stan", &x2, xptr);
}
```

If m is a member or base member of class X, the expression X::m is called a qualified name; it has the same type as m, and it is an lvalue only if m is an lvalue. It is important to note that, even if the class name X is hidden by a non-type name, the qualified name X::m will access the correct class member, m.

Class members cannot be added to a class by another section of your program. The class X cannot contain objects of class X, but can contain pointers or references to objects of class X (note the similarity with C’s structure and union types).

3.1.3.1.1.8.4 Nested Types

Tag or **typedef** names declared inside a class lexically belong to the scope of that class. Such names can, in general, be accessed only by using the **xxx::yyy** notation, except when in the scope of the appropriate class.

A class declared within another class is called a nested class. Its name is local to the enclosing class; the nested class is in the scope of the enclosing class. This is a purely lexical nesting. The nested class has no additional privileges in accessing members of the enclosing class (and vice versa).

Classes can be nested in this way to an arbitrary level, up to the limits of memory. Nested classes can be declared inside some class and defined later. For example,

```
struct outer
{
   typedef int t;  // 'outer::t' is a typedef name
   struct inner    // 'outer::inner' is a class
   {
      static int x;
   };
   static int x;
      int f();
   class deep;     // nested declaration
};
int outer::x;     // define static data member
int outer::f() {
   t x;           // 't' visible directly here
   return x;
   }
int outer::inner::x;    // define static data member
outer::t x;             //  have to use 'outer::t' here
class outer::deep { };  // define the nested class here
```

With CodeGear C++ 2.0, any tags or **typedef** names declared inside a class actually belong to the global (file) scope. For

example:

```
struct foo
{
   enum bar { x };   // 2.0 rules: 'bar' belongs to file scope
                     // 2.1 rules: 'bar' belongs to 'foo' scope
};
bar x;
```

The preceding fragment compiles without errors. But because the code is illegal under the 2.1 rules, a warning is issued as follows:

```
Warning: Use qualified name to access nested type 'foo::bar'
```

3.1.3.1.1.9 Class Objects

Class objects can be assigned (unless copying has been restricted), passed as arguments to functions, returned by functions (with some exceptions), and so on. Other operations on class objects and members can be user-defined in many ways, including definition of member and friend functions and the redefinition of standard functions and operators when used with objects of a certain class.

Redefined functions and operators are said to be overloaded. Operators and functions that are restricted to objects of a certain class (or related group of classes) are called member functions for that class. C++ offers the overloading mechanism that allows the same function or operator name can be called to perform different tasks, depending on the type or number of arguments or operands.

3.1.3.1.1.10 Virtual Base Classes

This section contains Virtual Base Class topics.

Topics

Name	Description
Virtual Base Classes (see page 403)	A **virtual** class is a base class that is passed to more than one derived class, as might happen with multiple inheritance. You cannot specify a base class more than once in a derived class:

3.1.3.1.1.10.1 Virtual Base Classes

A **virtual** class is a base class that is passed to more than one derived class, as might happen with multiple inheritance.

You cannot specify a base class more than once in a derived class:

```
class B { ... };
class D : B; B { ... }; //ILLEGAL
```

However, you can indirectly pass a base class to the derived class more than once:

```
class X : public B { ... };
class Y : public B { ... };
class Z : public X, public Y { ... }; //OK
```

In this case, each object of class Z has two sub-objects of class B.

If this causes problems, add the keyword **virtual** to the base class specifier. For example,

```
class X : virtual public B { ... };
class Y : virtual public B { ... };
class Z : public X, public Y { ... };
```

B is now a virtual base class, and class Z has only one sub-object of class B.

Constructors for Virtual Base Classes

Constructors for virtual base classes are invoked before any non-virtual base classes.

If the hierarchy contains multiple virtual base classes, the virtual base class constructors invoke in the order they were declared.

Any non-virtual bases are then constructed before the derived class constructor is called.

If a virtual class is derived from a non-virtual base, that non-virtual base will be first, so that the virtual base class can be properly

constructed. For example, this code

```
class X : public Y , virtual public Z
 X one;
```

produces this order:

```
Z(); // virtual base class initialization
Y(); // non-virtual base class
X(); // derived class
```

3.1.3.1.1.11 Class Types

The declaration creates a unique type, class type class-name. This lets you declare further class objects (or instances) of this type, and objects derived from this type (such as pointers to, references to, arrays of class-name, and so on):

```
class X { ... };
X x, &xr, *xptr, xarray[10];
/* four objects: type X, reference to X, pointer to X and array of X */
struct Y { ... };
Y y, &yr, *yptr, yarray[10];
// C would have
// struct Y y, *yptr, yarray[10];
union Z { ... };
Z z, &zr, *zptr, zarray[10];
// C would have
// union Z z, *zptr, zarray[10];
```

Note the difference between C and C++ structure and union declarations: The keywords **struct** and **union** are essential in C, but in C++, they are needed only when the class names, Y and Z, are hidden (see Class name scope)

3.1.3.1.1.12 Member Functions

A function declared without the **friend** specifier is known as a member function of the class. Functions declared with the **friend** modifier are called friend functions.

Member functions are often referred to as methods in Delphi documentation.

The same name can be used to denote more than one function, provided they differ in argument type or number of arguments.

3.1.3.1.1.13 VCL Class Declarations

Syntax

```
__declspec(<decl-modifier>)
```

Description

The decl-modifier argument can be **delphiclass** or **pascalimplementation**. These arguments should be used only with classes derived from VCL classes.

- You must use __declspec(delphiclass) for any forward declaration of classes that are directly or indirectly derived from TObject.
- Use the __declspec(pascalimplementation) modifier to indicate that a class has been implemented in the Delphi language. This modifier appears in a Delphi portability header file with a .hpp extension.

  Note: Another argument, delphireturn

  , is used internally to mark C++ classes for VCL-compatible handling in function calls as parameters and return values. The **delphiclass** argument is used to create classes that have the following VCL compatibility.
- VCL-compatible RTTI
- VCL-compatible constructor/destructor behavior
- VCL-compatible exception handling

A VCL-compatible class has the following restrictions.

- No virtual base classes or multiple inheritance is allowed.
- Must be dynamically allocated by using the global **new** operator.
- Copy and assignment constructors must be explicitly defined. The compiler does not automatically provide these constructors for VCL-derived classes.
- Must publicly inherit from another VCL class.

3.1.3.1.1.14 Class Methods

In C++Builder, a **class method** is a method that can be invoked on a class name, as well as on an instance of that class. In contrast, object methods can be invoked only on objects -- instances of a class.

How Class Methods Work in Delphi

The Delphi language (Object Pascal) supports class methods and a metaclass as described in the Class Methods section in the Delphi help topic Methods.

Here is a sample:

```
TTest = class;

// Declaring metaclass type
TTestClass = class of TTest;

TTest = class
public
  // Class methods
  class function add(I, J: Integer): Integer;
  class function GetClsName: string;

  // Virtual class method
  class function GetClsNameVirt: string; virtual;

  // Class getter and setter
  class function GetCount: Integer;
  class procedure SetCount(I: Integer);

  // Virtual class getter and setter
  class function GetStrProp: string; virtual;
  class procedure SetStrProp(N: string); virtual;
```

```
    // Class static
    class function GetStaticCount: Integer; static;
    class procedure SetStaticCount(I: Integer); static;

    // Class properties
    property Count: Integer read GetCount write SetCount; // Non-virtual
    property StrProp: string read GetStrProp write SetStrProp; // Virtual g/setters
  end;

  // Function that takes a class reference
  function RegisterTestType(Cls: TTestClass): boolean;
```

Class Methods as Static Methods with Explicit TMetaClass* Parameter

Prior to C++Builder 2009, class methods were represented as static methods with an explicit metaclass parameter. A metaclass is represented by a pointer to a TMetaClass instance or a TClass. This metaclass or class reference is obtained with the __classid extension, which returns a TMetaClass* instance for a class name.

Here is an example of this usage, attempting to define the same methods and properties as in the Delphi sample above. Note that some of the Delphi class method features cannot be done properly using this metaclass approach.

```
// All metaclass types are TMetaClass* in C++
typedef TMetaClass* TTestClass;

class DELPHICLASS TTest;
class PASCALIMPLEMENTATION TTest : public System::TObject
{
  typedef System::TObject inherited;
  public:
      // Class methods exposed as static methods with the 'hidden'
      // class reference explicit as the first parameter.
      static int __fastcall add(TMetaClass* vmt, int I, int J);
      static UnicodeString __fastcall GetClsName(TMetaClass* vmt);

      // Virtual class methods would be exposed as plain virtual methods with
      // the hidden class reference explicit as the first parameter.
      // This means that upon calling this method from C++, there would have
      // to be two 'hidden' parameters passed in--which would not work.
      virtual UnicodeString __fastcall GetClsNameVirt(TMetaClass* vmt);

      // Non-virtual methods are feasible to work with. These two methods
      // are typically overloaded with the first TMetaClass* parameter
      // hardcoded to __classid(TTest).
      static int __fastcall GetCount(TMetaClass* vmt);
      static void __fastcall SetCount(TMetaClass* vmt, int I);

      // You can overload these virtual setters and getters, but given
      // that the call is incorrect, the program fails
      // when accessing the property tied to these methods.
      virtual UnicodeString __fastcall GetStrProp(TMetaClass* vmt);
      virtual void __fastcall SetStrProp(TMetaClass* vmt, UnicodeString N);

      // Delphi class static method would be plain C++ static.
      static int __fastcall GetStaticCount();
      static void __fastcall SetStaticCount(int I);

      // Although the compiler allows these declarations,
      // because TMetaClass* is required, you'll get an error
      // from the C++ compiler upon attempting to access these
properties.
      __property int Count = {read=GetCount, write=SetCount, nodefault};
      __property UnicodeString StrProp = {read=GetStrProp, write=SetStrProp};};

extern PACKAGE bool __fastcall RegisterTestType(TMetaClass* Cls);
```

There are several limitations with this way of exposing class methods using an explicit TMetaClass* parameter:

- C++ code cannot properly invoke virtual class methods. C++ calls would have to pass two hidden this parameters: the pointer to the instance of the object and the explicit `TMetaClass*` parameter. However, the function expects only one `TMetaClass*` parameter.
- Even in cases where the call to a virtual class method succeeds, the C++ code must have an instance of the object to invoke the method, but a proper class method should be invokable without requiring an object instance.
- C++ code cannot properly access properties whose getters or setters are class methods, because there's no way to provide the `TMetaClass*` parameter, which must be explicit.

Class Methods Using __classmethod Keyword

C++Builder 2009 introduces class methods that remove the limitations listed above and provide a simpler and more intuitive syntax for class methods. Class methods are now declared with the new keyword **__classmethod**.

Here is how the code above is written using the **__classmethod** syntax:

```
// Class references still use TMetaClass*.
typedef TMetaClass* TTestClass;

class DELPHICLASS TTest;
class PASCALIMPLEMENTATION TTest : public System::TObject
{
  typedef System::TObject inherited;

  public:
      // The TMetaClass* parameter is now hidden.
      // The __classmethod keyword flags methods as class methods.
      __classmethod int __fastcall add(int I, int J);
      __classmethod UnicodeString __fastcall GetClsName();

      // Virtual methods can be used.
      __classmethod virtual UnicodeString __fastcall GetClsNameVirt();

      // Methods can access class properties
      __classmethod int __fastcall GetCount();
      __classmethod void __fastcall SetCount(int I);
      __classmethod virtual UnicodeString __fastcall GetStrProp();
      __classmethod virtual void __fastcall SetStrProp(UnicodeString N);

      // Class static methods still map to C++ static methods.
      static int __fastcall GetstaticCount();
      static void __fastcall SetstaticCount(int I);

      // Class properties
      __property int Count = {read=GetCount, write=SetCount, nodefault};
      __property UnicodeString StrProp = {read=GetStrProp, write=SetStrProp};
};
```

C++Builder does not provide for a way to declare a class reference other than by `TMetaClass*`. Hence, class methods are invoked with a typename or with an instance of a object. Virtual class methods are invoked the same way regular virtual methods are invoked, except that instead of the this pointer being pushed, the metaclass pointer is the hidden parameter.

This implementation provides two capabilities:

- Class methods can be virtual.
- Class properties can be defined.

Dynamic Dispatch of Virtual Class Methods

If you have a class method defined with **__classmethod** for a class that is derived from another class, you can't dynamically invoke the derived class's virtual method using a class name. However, you can invoke the proper method using an instance.

The "virtual" mechanism of class methods is analogous to virtual for regular methods. For regular methods, you get polymorphism only when using a pointer or a reference, because the vtable is then determined at run time. With a value instance, you don't get polymorphism because the vtable is determine at compile time.

Similarly, for class methods you get polymorphism with an instance but not with a type. To illustrate:

```
class TBase {
    virtual __classmethod void cfunc();
    virtual  void vfunc();
};

class TDerived: TBase {
    virtual __classmethod void cfunc();
    virtual void vfunc();
};

// Regular virtual methods
TDerived d;
d.vfunc();   //calls TDerived::vfunc;

TBase* bp = new TDerived();
bp->vfunc(); //calls TDerived::vfunc;

TBase& br = TDerived();
br.vfunc();  //calls TDerived::vfunc;

TBase b;
b.vfunc();   //calls TBase::vfunc
// Class virtual methods
TBase* b = new TDerived();
b->cfunc();         //calls version in TDerived--dynamic
TDerived::cfunc();  //calls version in TDerived--compile time--not dynamic
__classid(TDerived)->cfunc();  //compiler error
```

Updating Your Code to Use __classmethod

If you have C++ code that implements class methods using the older style class methods with a Metaclass * parameter, you can update your code to use the __classmethod syntax. Since the TMetaClass* parameter is now hidden, the signature and mangling of such class methods are different. The following table illustrates how to update common C++ constructs using class methods. It uses the add(int i, int j) method and the Count property from the __classmethod code sample above to illustrate the changes you would make.

Purpose of code	Old style “class static” code	Updated code using __classmethod
Function declaration	class TTest : public System::TObject { public: static int __fastcall add(TMetaClass* vmt, int I, int J); };	class TTest : public System::TObject { public: __classmethod int __fastcall add(int I, int J); };
Using __classid	TTest::add(__classid(TTest), 10, 20);	TTest::add(10, 20);
Using derived __classid	TTestDerived::add(__classid(TTestDerived), 10, 20);	TTestDerived::add(10, 20);
Using class instance	TTest* p = new TTest(); ... TTest::add(p->ClassType(), 10, 20);	TTest* p = new TTest(); ... p->add(10, 20);
Using derived instance	TTest* p = new TTestDerived(); ... TTest::add(p->ClassType(), 10, 20);	TTest* p = new TTestDerived(); ... p->add(10, 20);
Using class property	TTest* p = new TTest(); ... p->Count = 20;	TTest::Count = 20; //Using class name // Using instance TTest* p = new TTest(); ... p->Count = 20;

3.1.3.1.1.15 Static Properties

Static properties have been implemented in C++Builder 2009 to enhance compatibility with the Delphi language

Declaring Class Functions as Static

If property access functions (getters and setters) are declared as static, you can use the property directly from the class without specifying an object. For example:

```
class TMyClass : TComponent {
  static int x;
  static int GetX() { return x; }
  static void SetX( int i ) { x = i; }

  __property int X = { read = GetX, write = SetX }
};

TMyClass::X = 5;
int y = TMyClass::X;
```

Delphi also allows plain static methods as getters and setters of properties. Note that these static methods are not class methods; there is no hidden parameter. For example:

```
class TTest{
  static int __fastcall GetCount();
  static void __fastcall SetCount(int I);
public:
  __property int Count = {read=GetCount, write=SetCount};
};
```

In this case, you can then use the properties as this:

```
int c = TTest::Count;
TTest t;
int i = t.Count;
```

The C++ compiler already supports static properties that map to a member variable. For example:

```
class TEncoding  {
   static int Prop;
 public:
   __property int Count = { read=Prop };
};
int f(TEncoding& t) {
   return t.Count;
}
```

3.1.3.1.2 Class Templates Overview

This section contains Class Templates Overview topics.

Topics

Name	Description
Using Angle Brackets In Templates (see page 412)	Be careful when using the right angle bracket character upon instantiation:
Template Arguments (see page 412)	Multiple arguments are allowed as part of the class template declaration. Template arguments can also represent values in addition to data types:
Class Templates (see page 412)	A class template (also called a generic class or class generator) lets you define a pattern for class definitions. Consider the following example of a vector class (a one-dimensional array). Whether you have a vector of integers or any other type, the basic operations performed on the type are the same (insert, delete, index, and so on). With the element type treated as a type parameter to the class, the system will generate type-safe class definitions on the fly. As with function templates, an explicit template class specialization can be provided to override the automatic definition for a given type:... more (see page 412)
Eliminating Pointers In Templates (see page 412)	Another design technique is to include actual objects, making pointers unnecessary. This can also reduce the number of **virtual** function calls required, since the compiler knows the actual types of the objects. This is beneficial if the **virtual** functions are small enough to be effectively inlined. It's difficult to inline **virtual** functions when called through pointers, because the compiler doesn't know the actual types of the objects being pointed to.

Using Type-safe Generic Lists In Templates (see page 413)	In general, when you need to write lots of nearly identical things, consider using templates. The problems with the following class definition, a generic list class,

3.1.3.1.2.1 Using Angle Brackets In Templates

Be careful when using the right angle bracket character upon instantiation:

```
Buffer<char, (x > 100 ? 1024 : 64)> buf;
```

In the preceding example, without the parentheses around the second argument, the > between x and 100 would prematurely close the template argument list.

3.1.3.1.2.2 Template Arguments

Multiple arguments are allowed as part of the class template declaration. Template arguments can also represent values in addition to data types:

```
template<class T, int size = 64> class Buffer { ... };
```

Both non-type template arguments such as size and type arguments can have default values. The value supplied for a non-type template argument must be a constant expression:

```
const int N = 128;
int i = 256;
Buffer<int, 2*N> b1;// OK
Buffer<float, i> b2;// Error: i is not constant
```

Since each instantiation of a template class is indeed a class, it receives its own copy of static members. Similarly, template functions get their own copy of static local variables.

3.1.3.1.2.3 Class Templates

A class template (also called a generic class or class generator) lets you define a pattern for class definitions. Consider the following example of a vector class (a one-dimensional array). Whether you have a vector of integers or any other type, the basic operations performed on the type are the same (insert, delete, index, and so on). With the element type treated as a type parameter to the class, the system will generate type-safe class definitions on the fly.

As with function templates, an explicit template class specialization can be provided to override the automatic definition for a given type:

```
class Vector<char *> { ... };
```

The symbol Vector must always be accompanied by a data type in angle brackets. It cannot appear alone, except in some cases in the original template definition.

Exporting And Importing Templates (see page 432)

Eliminating Pointers In Templates (see page 412)

Template Arguments (see page 412)

3.1.3.1.2.4 Eliminating Pointers In Templates

Another design technique is to include actual objects, making pointers unnecessary. This can also reduce the number of **virtual** function calls required, since the compiler knows the actual types of the objects. This is beneficial if the **virtual** functions are small enough to be effectively inlined. It's difficult to inline **virtual** functions when called through pointers, because the compiler doesn't know the actual types of the objects being pointed to.

```
template <class T> aBase {
```

```
    .
    .
    .
 private:
  T buffer;
};
class anObject : public aSubject, public aBase<aFilebuf> {
    .
    .
    .
};
```

All the functions in aBase can call functions defined in aFilebuf directly, without having to go through a pointer. And if any of the functions in aFilebuf can be inlined, you'll get a speed improvement, because templates allow them to be inlined.

3.1.3.1.2.5 Using Type-safe Generic Lists In Templates

In general, when you need to write lots of nearly identical things, consider using templates. The problems with the following class definition, a generic list class,

```
class GList
{
 public:
   void insert( void * );
   void *peek();
    .
    .
    .
};
```

are that it isn't type-safe and common solutions need repeated class definitions. Since there's no type checking on what gets inserted, you have no way of knowing what results you'll get. You can solve the type-safe problem by writing a wrapper class:

```
class FooList : public GList {
 public:
   void insert( Foo *f ) { GList::insert( f ); }
   Foo *peek() { return (Foo *)GList::peek(); }
      .
      .
      .
};
```

This is type-safe. insert will only take arguments of type pointer-to-Foo or object-derived-from-Foo, so the underlying container will only hold pointers that in fact point to something of type Foo. This means that the cast in FooList::peek() is always safe, and you've created a true FooList. Now, to do the same thing for a BarList, a BazList, and so on, you need repeated separate class definitions. To solve the problem of repeated class definitions and type-safety, you can once again use templates. See the example for type-safe generic list class. The C++ Standard Template Library (STL) has a rich set of type-safe collection classes.

By using templates, you can create whatever type-safe lists you want, as needed, with a simple declaration. And there's no code generated by the type conversions from each wrapper class so there's no runtime overhead imposed by this type safety.

3.1.3.1.3 Compiler Template Switches

This section contains Compiler Template Switch topics.

Topics

Name	Description
Template Compiler Switches (see page 414)	The -Jg family of switches control how instances of templates are generated by the compiler. Every template instance encountered by the compiler will be affected by the value of the switch at the point where the first occurrence of that particular instance is seen by the compiler. For template functions the switch applies to the function instances; for template classes, it applies to all member functions and static data members of the template class. In all cases, this switch applies only to compiler-generated template instances and never to user-defined instances. It can be used, however, to tell the compiler which... more (see page 414)
Template Generation Semantics (see page 414)	The C++ compiler generates the following methods for template instances: • Those methods which were actually used • Virtual methods of an instance • All methods of explicitly instantiated classes The advantage of this behavior is that it results in significantly smaller object files, libraries and executable files, depending on how heavily you use templates. Optionally, you can use the '-Ja' switch to generate all methods. You can also force all of the out-of-line methods of a template instance to be generated by using the explicit template instantiation syntax defined in the ISO/ANSI C++ Standard. The syntax is: **template class** classname**<**template... more (see page 414)

3.1.3.1.3.1 Template Compiler Switches

The -Jg family of switches control how instances of templates are generated by the compiler. Every template instance encountered by the compiler will be affected by the value of the switch at the point where the first occurrence of that particular instance is seen by the compiler.

For template functions the switch applies to the function instances; for template classes, it applies to all member functions and static data members of the template class. In all cases, this switch applies only to compiler-generated template instances and never to user-defined instances. It can be used, however, to tell the compiler which instances will be user-defined so that they aren't generated from the template.

3.1.3.1.3.2 Template Generation Semantics

The C++ compiler generates the following methods for template instances:

- Those methods which were actually used
- Virtual methods of an instance
- All methods of explicitly instantiated classes

The advantage of this behavior is that it results in significantly smaller object files, libraries and executable files, depending on how heavily you use templates.

Optionally, you can use the '-Ja' switch to generate all methods.

You can also force all of the out-of-line methods of a template instance to be generated by using the explicit template instantiation syntax defined in the ISO/ANSI C++ Standard. The syntax is:

template class classname**<**template parameter**>;**

The following STL example directs the compiler to generate all out-of-line methods for the “list<char>” class, regardless of whether they are referenced by the user’s code:

```
template class list<char>
```

You can also explicitly instantiate a single method, or a single static data member of a template class, which means that the method is generated to the .OBJ even though it is not used:

```
template void classname <template parameter>:: methodname ();
```

3.1.3.1.4 Constructors And Destructors

This section contains Constructor and Destructor topics.

Topics

Name	Description
Introduction To Constructors And Destructors (see page 415)	There are several special member functions that determine how the objects of a class are created, initialized, copied, and destroyed. Constructors and destructors are the most important of these. They have many of the characteristics of normal member functions—you declare and define them within the class, or declare them within the class and define them outside—but they have some unique features: • They do not have return value declarations (not even **void**). • They cannot be inherited, though a derived class can call the base class’s constructors and destructors. • Constructors, like most C++ functions, can have default arguments or use member... more (see page 415)
Constructors (see page 416)	This section contains Constructor topics.
Destructors (see page 422)	This section contains Destructor topics.

3.1.3.1.4.1 Introduction To Constructors And Destructors

There are several special member functions that determine how the objects of a class are created, initialized, copied, and destroyed. Constructors and destructors are the most important of these. They have many of the characteristics of normal member functions—you declare and define them within the class, or declare them within the class and define them outside—but they have some unique features:

- They do not have return value declarations (not even **void**).
- They cannot be inherited, though a derived class can call the base class’s constructors and destructors.
- Constructors, like most C++ functions, can have default arguments or use member initialization lists.
- Destructors can be **virtual**, but constructors cannot. (See Virtual destructors.)
- You can’t take their addresses.

```
int main (void)
{
.
.
.
void *ptr = base::base;    // illegal
.
.
.
}
```

- Constructors and destructors can be generated by the compiler if they haven’t been explicitly defined; they are also invoked on many occasions without explicit calls in your program. Any constructor or destructor generated by the compiler will be public.

- You cannot call constructors the way you call a normal function. Destructors can be called if you use their fully qualified name.

```
{
.
.
.
X *p;
.
.
.
p->X::~X();                 // legal call of destructor
X::X();                     // illegal call of constructor
.
.
.
}
```

- The compiler automatically calls constructors and destructors when defining and destroying objects.
- Constructors and destructors can make implicit calls to operator **new** and operator **delete** if allocation is required for an object.
- An object with a constructor or destructor cannot be used as a member of a union.
- If no constructor has been defined for some class X to accept a given type, no attempt is made to find other constructors or conversion functions to convert the assigned value into a type acceptable to a constructor for class X. Note that this rule applies only to any constructor with one parameter and no initializers that use the "**=**" syntax.

```
class X { /* ... */ X(int); };
class Y { /* ... */ Y(X); };
Y a = 1;                    // illegal: Y(X(1)) not tried
```

If **class** X has one or more constructors, one of them is invoked each time you define an object x of **class** X. The constructor creates x and initializes it. Destructors reverse the process by destroying the class objects created by constructors.

Constructors are also invoked when local or temporary objects of a class are created; destructors are invoked when these objects go out of scope.

3.1.3.1.4.2 Constructors

This section contains Constructor topics.

Topics

Name	Description
Class Initialization (see page 417)	An object of a class with only public members and no constructors or base classes (typically a structure) can be initialized with an initializer list. If a class has a constructor, its objects must be either initialized or have a default constructor. The latter is used for objects not explicitly initialized. Objects of classes with constructors can be initialized with an expression list in parentheses. This list is used as an argument list to the constructor. An alternative is to use an equal sign followed by a single value. The single value can be the same type as the first... more (see page 417)
Constructor Defaults (see page 419)	The default constructor for **class** X is one that takes no arguments; it usually has the form X::X(). If no user-defined constructors exist for a class, the compiler generates a default constructor. On a declaration such as X x, the default constructor creates the object x. Like all functions, constructors can have default arguments. For example, the constructor
Constructors (see page 419)	Constructors are distinguished from all other member functions by having the same name as the class they belong to. When an object of that class is created or is being copied, the appropriate constructor is called implicitly. Constructors for global variables are called before the main function is called. Global variable constructors are also called prior to **#pragma startup** functions. Local objects are created as the scope of the variable becomes active. A constructor is also invoked when a temporary object of the class is created.

Order Of Calling Constructors (see page 420)	In the case where a class has one or more base classes, the base class constructors are invoked before the derived class constructor. The base class constructors are called in the order they are declared. For example, in this setup,
Overloading Constructors (see page 421)	Constructors can be overloaded, allowing objects to be created, depending on the values being used for initialization.
The Copy Constructor (see page 421)	A copy constructor for **class** X is one that can be called with a single argument of type X as follows:

3.1.3.1.4.2.1 Class Initialization

An object of a class with only public members and no constructors or base classes (typically a structure) can be initialized with an initializer list. If a class has a constructor, its objects must be either initialized or have a default constructor. The latter is used for objects not explicitly initialized.

Objects of classes with constructors can be initialized with an expression list in parentheses. This list is used as an argument list to the constructor. An alternative is to use an equal sign followed by a single value. The single value can be the same type as the first argument accepted by a constructor of that class, in which case either there are no additional arguments, or the remaining arguments have default values. It could also be an object of that class type. In the former case, the matching constructor is called to create the object. In the latter case, the copy constructor is called to initialize the object.

```
class X
{
   int i;
public:
   X();          // function bodies omitted for clarity
   X(int x);
   X(const X&);
};
void main()
{
   X one;         // default constructor invoked
   X two(1);      // constructor X::X(int) is used
   X three = 1;   // calls X::X(int)
   X four = one; // invokes X::X(const X&) for copy
   X five(two);   // calls X::X(const X&)
}
```

The constructor can assign values to its members in two ways:

1. It can accept the values as parameters and make assignments to the member variables within the function body of the constructor:

```
class X
{
   int a, b;
public:
   X(int i, int j) { a = i; b = j }
};
```

2. An initializer list can be used prior to the function body:

```
class X
{
   int a, b, &c;  // Note the reference variable.
public:
   X(int i, int j) : a(i), b(j), c(a) {}
};
```

The initializer list is the only place to initialize a reference variable.

In both cases, an initialization of X x(1, 2) assigns a value of 1 to x::a and 2 to x::b. The second method, the initializer list, provides a mechanism for passing values along to base class constructors.

Note: Base class constructors must be declared as either public

or **protected** to be called from a derived class.

```
class base1
{
   int x;
public:
   base1(int i) { x = i; }
};
class base2
{
   int x;
public:
   base2(int i) : x(i) {}
};
class top : public base1, public base2
{
   int a, b;
public:
   top(int i, int j) : base1(i*5), base2(j+i), a(i) { b = j;}
};
```

With this class hierarchy, a declaration of top one(1, 2) would result in the initialization of base1 with the value 5 and base2 with the value 3. The methods of initialization can be intermixed.

As described previously, the base classes are initialized in declaration order. Then the members are initialized, also in declaration order, independent of the initialization list.

```
class X
{
  int a, b;
public:
  X(int i, j) :  a(i), b(a+j) {}
};
```

With this class, a declaration of X x(1,1) results in an assignment of 1 to x::a and 2 to x::b.

Base class constructors are called prior to the construction of any of the derived classes members. If the values of the derived class are changed, they will have no effect on the creation of the base class.

```
class base
{
   int x;
public:
   base(int i) : x(i) {}
};
class derived : base
{
   int a;
public:
   derived(int i) : a(i*10), base(a) { } // Watch out! Base will be
                                         // passed an uninitialized 'a'
};
```

With this class setup, a call of derived d(1) will not result in a value of 10 for the base class member x. The value passed to the base class constructor will be undefined.

When you want an initializer list in a non-inline constructor, don't place the list in the class definition. Instead, put it at the point at which the function is defined.

```
derived::derived(int i) : a(i)
{
  .
  .
  .
}
```

Invoking Destructors (see page 424)

Atexit (see page 426)

Exit And Destructors (see page 423)

abort And Destructors (see page 425)

Virtual Destructors (see page 424)

3.1.3.1.4.2.2 Constructor Defaults

The default constructor for **class** X is one that takes no arguments; it usually has the form X::X(). If no user-defined constructors exist for a class, the compiler generates a default constructor. On a declaration such as X x, the default constructor creates the object x.

Like all functions, constructors can have default arguments. For example, the constructor

```
X::X(int, int = 0)
```

can take one or two arguments. When presented with one argument, the missing second argument is assumed to be a zero **int**. Similarly, the constructor

```
X::X(int = 5, int = 6)
```

could take two, one, or no arguments, with appropriate defaults. However, the default constructor X::X() takes no arguments and must not be confused with, say, X::X(int = 0), which can be called with no arguments as a default constructor, or can take an argument.

You should avoid ambiguity in defining constructors. In the following case, the two default constructors are ambiguous:

```
class X
{
public:
   X();
   X(int i = 0);
};
int main()
{
   X one(10);  // OK; uses X::X(int)
   X two;      // Error;ambiguous whether to call X::X() or
               // X::X(int = 0)
   return 0;
}
```

See Also

Constructors (see page 419)

3.1.3.1.4.2.3 Constructors

Constructors are distinguished from all other member functions by having the same name as the class they belong to. When an object of that class is created or is being copied, the appropriate constructor is called implicitly.

Constructors for global variables are called before the main function is called. Global variable constructors are also called prior to **#pragma startup** functions.

Local objects are created as the scope of the variable becomes active. A constructor is also invoked when a temporary object of the class is created.

```
class X {
public:
```

```
   X();   // class X constructor
};
```

A **class** X constructor cannot take X as an argument:

```
class X {
public:
   X(X);                    // illegal
};
```

The parameters to the constructor can be of any type except that of the class it's a member of. The constructor can accept a reference to its own class as a parameter; when it does so, it is called the copy constructor. A constructor that accepts no parameters is called the default constructor.

3.1.3.1.4.2.4 Order Of Calling Constructors

In the case where a class has one or more base classes, the base class constructors are invoked before the derived class constructor. The base class constructors are called in the order they are declared.

For example, in this setup,

```
class Y {...}
class X : public Y {...}
X one;
```

the constructors are called in this order:

```
Y();   // base class constructor
X();   // derived class constructor
```

For the case of multiple base classes,

```
class X : public Y, public Z
X one;
```

the constructors are called in the order of declaration:

```
Y();  // base class constructors come first
Z();
X();
```

Constructors for virtual base classes are invoked before any nonvirtual base classes. If the hierarchy contains multiple virtual base classes, the virtual base class constructors are invoked in the order in which they were declared. Any nonvirtual bases are then constructed before the derived class constructor is called.

If a virtual class is derived from a nonvirtual base, that nonvirtual base will be first so that the virtual base class can be properly constructed. The code:

```
class X : public Y, virtual public Z
X one;
```

produces this order:

```
Z();   // virtual base class initialization
Y();   // nonvirtual base class
X();   // derived class
```

Or, for a more complicated example:

```
class base;
class base2;
class level1 : public base2, virtual public base;
class level2 : public base2, virtual public base;
class toplevel : public level1, virtual public level2;
toplevel view;
```

The construction order of view would be as follows:

```
base();      // virtual base class highest in hierarchy
             // base is constructed only once
base2();     // nonvirtual base of virtual base level2
             // must be called to construct level2
level2();    // virtual base class
base2();     // nonvirtual base of level1
level1();    // other nonvirtual base
toplevel();
```

If a class hierarchy contains multiple instances of a virtual base class, that base class is constructed only once. If, however, there exist both virtual and nonvirtual instances of the base class, the class constructor is invoked a single time for all virtual instances and then once for each nonvirtual occurrence of the base class.

Constructors for elements of an array are called in increasing order of the subscript.

3.1.3.1.4.2.5 Overloading Constructors

Constructors can be overloaded, allowing objects to be created, depending on the values being used for initialization.

```
class X {
   int    integer_part;
   double double_part;
public:
   X(int i)    { integer_part = i; }
   X(double d) { double_part = d; }
};
int main()
{
   X one(10);   // invokes X::X(int) and sets integer_part to 10
   X one(3.14); // invokes X::X(double) setting double_part to 3.14
   return 0;
}
```

Virtual Destructors (see page 424)

3.1.3.1.4.2.6 The Copy Constructor

A copy constructor for **class** X is one that can be called with a single argument of type X as follows:

```
X::X(X&)
```

or

```
X::X(const X&)
```

or

```
X::X(const X&, int = 0)
```

Default arguments are also allowed in a copy constructor. Copy constructors are invoked when initializing a class object, typically when you declare with initialization by another class object:

```
X x1;
X x2 = x1;
X x3(x1);
```

The compiler generates a copy constructor for **class** X if one is needed and no other constructor has been defined in **class** X. The copy constructor that is generated by the compiler lets you safely start programming with simple data types. You need to make your own definition of the copy constructor if your program creates aggregate, complex types such as **class**, **struct**, and array types. The copy constructor is also called when you pass a class argument by value to a function.

See also the discussion of member-by-member class assignment. You should define the copy constructor if you overload the assignment operator.

3.1.3.1.4.3 Destructors

This section contains Destructor topics.

Topics

Name	Description
Destructors (see page 423)	The destructor for a class is called to free members of an object before the object is itself destroyed. The destructor is a member function whose name is that of the class preceded by a tilde (~). A destructor cannot accept any parameters, nor will it have a return type or value declared.
Exit And Destructors (see page 423)	When you call exit from within a program, destructors are not called for any local variables in the current scope. Global variables are destroyed in their normal order.
Invoking Destructors (see page 424)	A destructor is called implicitly when a variable goes out of its declared scope. Destructors for local variables are called when the block they are declared in is no longer active. In the case of global variables, destructors are called as part of the exit procedure after the main function. When pointers to objects go out of scope, a destructor is not implicitly called. This means that the **delete** operator must be called to destroy such an object. Destructors are called in the exact opposite order from which their corresponding constructors were called (see Order of calling constructors).
Virtual Destructors (see page 424)	A destructor can be declared as **virtual**. This allows a pointer to a base class object to call the correct destructor in the event that the pointer actually refers to a derived class object. The destructor of a class derived from a class with a **virtual** destructor is itself **virtual**.

abort And Destructors (see page 425)	If you call **abort** anywhere in a program, no destructors are called, not even for variables with a global scope. A destructor can also be invoked explicitly in one of two ways: indirectly through a call to **delete**, or directly by using the destructor's fully qualified name. You can use **delete** to destroy objects that have been allocated using **new**. Explicit calls to the destructor are necessary only for objects allocated a specific address through calls to **new**
atexit, #pragma exit, And Destructors (see page 426)	All global objects are active until the code in all exit procedures has executed. Local variables, including those declared in the main function, are destroyed as they go out of scope. The order of execution at the end of a program is as follows: • atexit() functions are executed in the order they were inserted. • **#pragma exit** functions are executed in the order of their priority codes. • Destructors for global variables are called.

3.1.3.1.4.3.1 Destructors

The destructor for a class is called to free members of an object before the object is itself destroyed. The destructor is a member function whose name is that of the class preceded by a tilde (~). A destructor cannot accept any parameters, nor will it have a return type or value declared.

```
#include <stdlib.h>
class X
{
public:
   ~X(){};  // destructor for class X
};
```

If a destructor isn't explicitly defined for a class, the compiler generates one.

Atexit (see page 426)

abort And Destructors (see page 425)

Virtual Destructors (see page 424)

3.1.3.1.4.3.3 Invoking Destructors

A destructor is called implicitly when a variable goes out of its declared scope. Destructors for local variables are called when the block they are declared in is no longer active. In the case of global variables, destructors are called as part of the exit procedure after the main function.

When pointers to objects go out of scope, a destructor is not implicitly called. This means that the **delete** operator must be called to destroy such an object.

Destructors are called in the exact opposite order from which their corresponding constructors were called (see Order of calling constructors).

See Also

Class Initialization (see page 417)

Atexit (see page 426)

Exit And Destructors (see page 423)

abort And Destructors (see page 425)

Virtual Destructors (see page 424)

3.1.3.1.4.3.4 Virtual Destructors

A destructor can be declared as **virtual**. This allows a pointer to a base class object to call the correct destructor in the event that the pointer actually refers to a derived class object. The destructor of a class derived from a class with a **virtual** destructor is itself **virtual**.

```
/* How virtual affects the order of destructor calls.
   Without a virtual destructor in the base class, the derived
   class destructor won't be called. */
#include <iostream>
class color {
public:
   virtual ~color() {  // Virtual destructor
      std::cout << "color dtor\n";
      }
};
class red : public color {
public:
   ~red() {  // This destructor is also virtual
      std::cout << "red dtor\n";
      }
};
class brightred : public red {
public:
   ~brightred() {  // This destructor is also virtual
       std::cout << "brightred dtor\n";
       }
};
int main()
{
   color *palette[3];
   palette[0] = new red;
   palette[1] = new brightred;
   palette[2] = new color;
   // The destructors for red and color are called.
   delete palette[0];
   std::cout << std::endl;
   // The destructors for bright red, red, and color are called.
   delete palette[1];
   std::cout << std::endl;
```

```
   // The destructor for color is called.
   delete palette[2];
   return 0;
}
```

Program Output:

```
red dtor
color dtor
brightred dtor
red dtor
color dtor
color dtor
```

However, if no destructors are declared as virtual, **delete** palette[0], **delete** palette[1], and **delete** palette[2] would all call only the destructor for class color. This would incorrectly destruct the first two elements, which were actually of type red and brightred.

3.1.3.1.4.3.5 abort And Destructors

If you call **abort** anywhere in a program, no destructors are called, not even for variables with a global scope.

A destructor can also be invoked explicitly in one of two ways: indirectly through a call to **delete**, or directly by using the destructor's fully qualified name. You can use **delete** to destroy objects that have been allocated using **new**. Explicit calls to the destructor are necessary only for objects allocated a specific address through calls to **new**

```
#include <stdlib.h>
class X {
public:
   .
   .
   .
    ~X(){};
   .
   .
   .
};
void* operator new(size_t size, void *ptr)
{
   return ptr;
}
char buffer[sizeof(X)];
void main()
{
   X* pointer = new X;
   X* exact_pointer;
   exact_pointer = new(&buffer) X; // pointer initialized at
                                   // address of buffer
.
.
.
   delete pointer;                 // delete used to destroy pointer
   exact_pointer->X::~X();         // direct call used to deallocate
}
```

3.1.3.1.5 C++ namespaces

This section contains C++ name space topics.

Topics

Name	Description
Declaring A namespace (see page 427)	An original namespace declaration should use an identifier that has not been previously used as a global identifier.
Accessing Elements Of A namespace (see page 427)	There are three ways to access the elements of a namespace: by explicit access qualification, the using-declaration, or the using-directive. Remember that no matter which namespace you add to your local scope, identifiers in global scope (global scope is just another namespace) are still accessible by using the scope resolution operator **::**. • Explicit access qualification (see page 428) • Using directive (see page 429) • Using declaration (see page 572) **Accessing namespaces in classes** You cannot use a **using** directive inside a class. However, the **using** declarative is allowed and can be quite useful.
Anonymous namespaces (see page 427)	The C++ grammar allows you to define anonymous namespaces. To do this, you use the keyword **namespace** with no identifier before the enclosing brace.
Defining A namespace (see page 428)	The grammar for defining a namespace is

Explicit Access Qualification (see page 428)	You can explicitly qualify each member of a namespace. To do so, you use the namespace identifier together with the **::** scope resolution operator followed by the member name. For example, to access a specific member of namespace ALPHA, you write:
Extending A namespace (see page 428)	Namespaces are discontinuous and open for additional development. If you redeclare a namespace, the effect is that you extend the original namespace by adding new declarations. Any extensions that are made to a namespace after a using-declaration, will not be known at the point at which the using-declaration occurs. Therefore, all overloaded versions of some function should be included in the namespace before you declare the function to be in use.
namespace Alias (see page 429)	You can use an alternate name to refer to a namespace identifier. An alias is useful when you need to refer to a long, unwieldy namespace identifier.
using Directive (see page 429)	If you want to use several (or all of) the members of a namespace, C++ provides an easy way to get access to the complete namespace. The using-directive causes all identifiers in a namespace to be in scope at the point that the using-directive statement is made. The grammar for the using-directive is as follows. using-directive: **using namespace ::** opt nested-name-specifier opt namespace-name; The using-directive is transitive. When you apply the using directive to a namespace that contains using directives within itself, you get access to those namespaces as well. For example, if you apply the using directive in your... more (see page 429)

3.1.3.1.5.1 Declaring A namespace

An original namespace declaration should use an identifier that has not been previously used as a global identifier.

```
namespace alpha {  /* ALPHA is the identifier of this namespace. */
  /* your program declarations */
  long double LD;
  float f(float y) { return y; }
  }
```

A namespace identifier must be known in all translation units where you intend to access its elements.

See Also

namespace Alias (see page 429)

3.1.3.1.5.2 Accessing Elements Of A namespace

There are three ways to access the elements of a namespace: by explicit access qualification, the using-declaration, or the using-directive. Remember that no matter which namespace you add to your local scope, identifiers in global scope (global scope is just another namespace) are still accessible by using the scope resolution operator **::**.

- Explicit access qualification (see page 428)
- Using directive (see page 429)
- Using declaration (see page 572)

Accessing namespaces in classes

You cannot use a **using** directive inside a class. However, the **using** declarative is allowed and can be quite useful.

See Also

using Directive (see page 429)

using (declaration) (see page 572)

3.1.3.1.5.3 Anonymous namespaces

The C++ grammar allows you to define anonymous namespaces. To do this, you use the keyword **namespace** with no identifier before the enclosing brace.

```
namespace {          // Anonymous namespace
   // Declarations
   }
```

All anonymous, unnamed namespaces in global scope (that is, unnamed namespaces that are not nested) of the same translation unit share the same namespace. This way you can make static declarations without using the **static** keyword.

Each identifier that is enclosed within an unnamed namespace is unique within the translation unit in which the unnamed namespace is defined.

3.1.3.1.5.4 Defining A namespace

The grammar for defining a namespace is

```
original-namespace-name:
    identifier
 namespace-definition:
    original-namespace-definition
    extension-namespace-definition
    unnamed-namespace-definition
```

Grammatically, there are three ways to define a namespace with the **namespace** keyword:

```
original-namespace-definition:
    namespace identifier { namespace-body }
extension-namespace-definition:
    namespace original-namespace-name { namespace-body }
unnamed-namespace-definition:
    namespace { namespace-body }
```

The body is an optional sequence of declarations. The grammar is

```
namespace-body:
    declaration-seq opt
```

See Also

Declaring A namespace (see page 427)

Extending A namespace (see page 428)

3.1.3.1.5.5 Explicit Access Qualification

You can explicitly qualify each member of a namespace. To do so, you use the namespace identifier together with the **::** scope resolution operator followed by the member name. For example, to access a specific member of namespace ALPHA, you write:

```
ALPHA::LD;  // Access a variable
ALPHA::f;   // Access a function
```

Explicit access qualification can always be used to resolve ambiguity. No matter which namespace (except anonymous namespace) is being used in your subsystem, you can apply the scope resolution operator **::** to access identifiers in any namespace (including a namespace already being used in the local scope) or the global namespace. Therefore, any identifier in the application can be accessed with sufficient qualification.

New-style typecasting

This section presents a discussion of alternate methods for making a typecast. The methods presented here augment the earlier cast expressions (which are still available) in the C language.

Types cannot be defined in a cast.

3.1.3.1.5.6 Extending A namespace

Namespaces are discontinuous and open for additional development. If you redeclare a namespace, the effect is that you extend

the original namespace by adding new declarations. Any extensions that are made to a namespace after a using-declaration, will not be known at the point at which the using-declaration occurs. Therefore, all overloaded versions of some function should be included in the namespace before you declare the function to be in use.

3.1.3.1.5.7 namespace Alias

You can use an alternate name to refer to a namespace identifier. An alias is useful when you need to refer to a long, unwieldy namespace identifier.

```
namespace BORLAND_SOFTWARE_CORPORATION {
   /* namespace-body */
   namespace NESTED_BORLAND_SOFTWARE_CORPORATION {
      /* namespace-body */
      }
   }
// Alias namespace
namespace BI = BORLAND_SOFTWARE_CORPORATION;
// Use access qualifier to alias a nested namespace
namespace NBI = BORLAND_SOFTWARE_CORPORATION::NESTED_BORLAND_SOFTWARE_CORPORATION;
```

3.1.3.1.5.8 using Directive

If you want to use several (or all of) the members of a namespace, C++ provides an easy way to get access to the complete namespace. The using-directive causes all identifiers in a namespace to be in scope at the point that the using-directive statement is made. The grammar for the using-directive is as follows.

using-directive:

using namespace :: opt nested-name-specifier opt namespace-name;

The using-directive is transitive. When you apply the using directive to a namespace that contains using directives within itself, you get access to those namespaces as well. For example, if you apply the using directive in your program, you also get namespaces `qux`, `foo`, and `bar`.

```
namespace qux {
   using namespace foo;  // This has been defined previously
   using namespace bar;  // This also has been defined previously
   }
```

The using-directive does not add any identifiers to your local scope. Therefore, an identifier defined in more than one namespace won't be a problem until you actually attempt to use it. Local scope declarations take precedence by hiding all other similar declarations.

Warning: Do not use the using

directive in header files. You might accidentally break namespaces in client code.

Accessing Elements Of A namespace (see page 427)

using (declaration) (see page 572)

3.1.3.1.6 C++ Scope

This section contains C++ Scope topics.

Topics

Name	Description
C++ Scope (see page 430)	The lexical scoping rules for C++, apart from class scope, follow the general rules for C, with the proviso that C++, unlike C, permits both data and function declarations to appear wherever a statement might appear. The latter flexibility means that care is needed when interpreting such phrases as “enclosing scope” and “point of declaration.”
C++ Scoping Rules Summary (see page 431)	The following rules apply to all names, including **typedef** names and class names, provided that C++ allows such names in the particular context discussed: • The name itself is tested for ambiguity. If no ambiguities are detected within its scope, the access sequence is initiated. • If no access control errors occur, the type of the object, function, class, **typedef**, and so on, is tested. • If the name is used outside any function and class, or is prefixed by the unary scope access operator ::, and if the name is not qualified by the binary :: operator or the member selection... more (see page 431)
Class Scope (see page 431)	The name M of a member of a class X has class scope “local to X”; it can be used only in the following situations: • In member functions of X • In expressions such as x.M, where x is an object of X • In expressions such as xptr->M, where xptr is a pointer to an object of X • In expressions such as X::M or D::M, where D is a derived class of X • In forward references within the class of which it is a member Names of functions declared as friends of X are not members of X; their names simply... more (see page 431)
Hiding (see page 432)	A name can be hidden by an explicit declaration of the same name in an enclosed block or in a class. A hidden class member is still accessible using the scope modifier with a class name: X::M. A hidden file scope (global) name can be referenced with the unary operator :: (for example, ::g). A class name X can be hidden by the name of an object, function, or enumerator declared within the scope of X, regardless of the order in which the names are declared. However, the hidden class name X can still be accessed by prefixing X with... more (see page 432)

3.1.3.1.6.1 C++ Scope

The lexical scoping rules for C++, apart from class scope, follow the general rules for C, with the proviso that C++, unlike C, permits both data and function declarations to appear wherever a statement might appear. The latter flexibility means that care is needed when interpreting such phrases as “enclosing scope” and “point of declaration.”

See Also

Class Scope (see page 431)

Hiding (see page 432)

C++ Scoping Rules Summary (see page 431)

3.1.3.1.6.2 C++ Scoping Rules Summary

The following rules apply to all names, including **typedef** names and class names, provided that C++ allows such names in the particular context discussed:

- The name itself is tested for ambiguity. If no ambiguities are detected within its scope, the access sequence is initiated.
- If no access control errors occur, the type of the object, function, class, **typedef**, and so on, is tested.
- If the name is used outside any function and class, or is prefixed by the unary scope access operator ::, and if the name is not qualified by the binary :: operator or the member selection operators **.** and **->**, then the name must be a global object, function, or enumerator.
- If the name n appears in any of the forms X::n, x.n (where x is an object of X or a reference to X), or ptr->n (where ptr is a pointer to X), then n is the name of a member of X or the member of a class from which X is derived.
- Any name that hasn't been discussed yet and that is used in a static member function must either be declared in the block it occurs in or in an enclosing block, or be a global name. The declaration of a local name n hides declarations of n in enclosing blocks and global declarations of n. Names in different scopes are not overloaded.
- Any name that hasn't been discussed yet and that is used in a nonstatic member function of class X must either be declared in the block it occurs in or in an enclosing block, be a member of class X or a base class of X, or be a global name. The declaration of a local name n hides declarations of n in enclosing blocks, members of the function's class, and global declarations of n. The declaration of a member name hides declarations of the same name in base classes.
- The name of a function argument in a function definition is in the scope of the outermost block of the function. The name of a function argument in a nondefining function declaration has no scope at all. The scope of a default argument is determined by the point of declaration of its argument, but it can't access local variables or nonstatic class members. Default arguments are evaluated at each point of call.
- A constructor initializer is evaluated in the scope of the outermost block of its constructor, so it can refer to the constructor's argument names.

See Also

C++ Scope (see page 430)

Class Scope (see page 431)

Hiding (see page 432)

3.1.3.1.6.3 Class Scope

The name M of a member of a class X has class scope "local to X"; it can be used only in the following situations:

- In member functions of X
- In expressions such as x.M, where x is an object of X
- In expressions such as xptr->M, where xptr is a pointer to an object of X
- In expressions such as X::M or D::M, where D is a derived class of X
- In forward references within the class of which it is a member

Names of functions declared as friends of X are not members of X; their names simply have enclosing scope.

See Also

C++ Scope (see page 430)

Hiding (see page 432)

C++ Scoping Rules Summary (see page 431)

3.1.3.1.6.4 Hiding

A name can be hidden by an explicit declaration of the same name in an enclosed block or in a class. A hidden class member is still accessible using the scope modifier with a class name: X::M. A hidden file scope (global) name can be referenced with the unary operator :: (for example, ::g). A class name X can be hidden by the name of an object, function, or enumerator declared within the scope of X, regardless of the order in which the names are declared. However, the hidden class name X can still be accessed by prefixing X with the appropriate keyword: **class**, **struct**, or **union**.

The point of declaration for a name x is immediately after its complete declaration but before its initializer, if one exists.

C++ Scope (see page 430)

Class Scope (see page 431)

C++ Scoping Rules Summary (see page 431)

3.1.3.1.7 Exporting And Importing Templates

This section contains Exporting And Importing Template topics.

Topics

Name	Description
Exporting And Importing Templates (see page 432)	The declaration of a template function or template class needs to be sufficiently flexible to allow it to be used in either a dynamic link library (shared library) or an executable file. The same template declaration should be available as an import and/or export, or without a modifier. To be completely flexible, the header file template declarations should not use __**export** or __**import** modifiers. This allows the user to apply the appropriate modifier at the point of instantiation depending on how the instantiation is to be used. The following steps demonstrate exporting and importing of templates. The source code is... more (see page 432)

3.1.3.1.7.1 Exporting And Importing Templates

The declaration of a template function or template class needs to be sufficiently flexible to allow it to be used in either a dynamic link library (shared library) or an executable file. The same template declaration should be available as an import and/or export, or without a modifier. To be completely flexible, the header file template declarations should not use __**export** or __**import** modifiers. This allows the user to apply the appropriate modifier at the point of instantiation depending on how the instantiation is to be used.

The following steps demonstrate exporting and importing of templates. The source code is organized in three files. Using the header file, code is generated in the dynamic link library.

1. Exportable/Importable Template Declarations

The header file contains all template class and template function declarations. An export/import version of the templates can be instantiated by defining the appropriate macro at compile time.

2. Compiling Exportable Templates

Write the source code for a dynamic link library. When compiled, this library has reusable export code for templates.

3. Using ImportTemplates

Now you can write a calling function that uses templates. This executable file is linked to the dynamic link library. Only objects that are not declared in the header file and which are instantiated in the main function cause the compiler to generate new code. Code for a newly instantiated object is written into main.obj file.

3.1.3.1.8 Function Templates Overview

This section contains Function Templates Overview topics.

Topics

Name	Description
Function Templates (see page 433)	Consider a function max(x, y) that returns the larger of its two arguments. x and y can be of any type that has the ability to be ordered. But, since C++ is a strongly typed language, it expects the types of the parameters x and y to be declared at compile time. Without using templates, many overloaded versions of max are required, one for each data type to be supported even though the code for each version is essentially identical. Each version compares the arguments and returns the larger. One way around this problem is to use a macro:
Implicit And Explicit Template Functions (see page 434)	When doing overload resolution (following the steps of looking for an exact match), the compiler ignores template functions that have been generated implicitly by the compiler.
Overriding A Template Function (see page 434)	The previous example is called a function template (or generic function, if you like). A specific instantiation of a function template is called a template function. Template function instantiation occurs when you take the function address, or when you call the function with defined (non-generic) data types. You can override the generation of a template function for a specific type with a non-template function:

3.1.3.1.8.1 Function Templates

Consider a function max(x, y) that returns the larger of its two arguments. x and y can be of any type that has the ability to be ordered. But, since C++ is a strongly typed language, it expects the types of the parameters x and y to be declared at compile time. Without using templates, many overloaded versions of max are required, one for each data type to be supported even though the code for each version is essentially identical. Each version compares the arguments and returns the larger.

One way around this problem is to use a macro:

```
#define max(x,y) ((x > y) ? x : y)
```

However, using the #**define** circumvents the type-checking mechanism that makes C++ such an improvement over C. In fact, this use of macros is almost obsolete in C++. Clearly, the intent of max(x, y) is to compare compatible types. Unfortunately, using the macro allows a comparison between an **int** and a **struct**, which are incompatible.

Another problem with the macro approach is that substitution will be performed where you don't want it to be. By using a template instead, you can define a pattern for a family of related overloaded functions by letting the data type itself be a parameter:

```
template <class T> T max(T x, T y){
   return (x > y) ? x : y;
   };
```

The data type is represented by the template argument **<class T>**. When used in an application, the compiler generates the appropriate code for the max function according to the data type actually used in the call:

```
int i;
Myclass a, b;
int j = max(i,0);       // arguments are integers
Myclass m = max(a,b);   // arguments are type Myclass
```

Any data type (not just a class) can be used for **<class T>**. The compiler takes care of calling the appropriate **operator>()**, so you can use max with arguments of any type for which **operator>()** is defined.

See Also

Exporting And Importing Templates (see page 432)

Implicit And Explicit Template Functions (see page 434)

3.1.3.1.8.2 Implicit And Explicit Template Functions

When doing overload resolution (following the steps of looking for an exact match), the compiler ignores template functions that have been generated implicitly by the compiler.

```
template<class T> T max(T a, T b){
        return  (a > b) ? a : b;
}
void f(int i, char c)
{
    max(i, i);      // calls max(int ,int )
    max(c, c);      // calls max(char,char)
    max(i, c);      // no match for max(int,char)
    max(c, i);      // no match for max(char,int)
}
```

This code results in the following error messages:

```
Could not find a match for 'max(int,char)' in function f(int,char)Could not find a match for
'max(char,int)' in function f(int,char)
Could not find a match for 'max(char,int)' in function f(int,char)
```

If the user explicitly declares a function, this function, on the other hand, will participate fully in overload resolution. See the example of explicit function.

When searching for an exact match for template function parameters, trivial conversions are considered to be exact matches. See the example on trivial conversions.

Template functions with derived class pointer or reference arguments are permitted to match their public base classes. See the example of base class referencing.

3.1.3.1.8.3 Overriding A Template Function

The previous example is called a function template (or generic function, if you like). A specific instantiation of a function template is called a template function. Template function instantiation occurs when you take the function address, or when you call the function with defined (non-generic) data types. You can override the generation of a template function for a specific type with a non-template function:

```
#include <string.h>
char *max(char *x, char *y){
   return(strcmp(x,y) > 0) ? x : y;
}
```

If you call the function with string arguments, it's executed in place of the automatic template function. In this case, calling the function avoided a meaningless comparison between two pointers.

Only trivial argument conversions are performed with compiler-generated template functions.

The argument type(s) of a template function must use all of the template formal arguments. If it doesn't, there is no way of deducing the actual values for the unused template arguments when the function is called.

3.1.3.1.9 The new And delete Operators

This section contains new And delete Operator topics.

Topics

Name	Description
Handling Errors For The New Operator (see page 435)	By default, **new** throws the bad_alloc exception when a request for memory allocation cannot be satisfied. You can define a function to be called if the **new** operator fails. To tell the **new** operator about the new-handler function, use set_new_handler and supply a pointer to the new-handler. If you want **new** to return null on failure, you must use set_new_handler(0) .
Operator new Placement Syntax (see page 436)	The placement syntax for **operator new( )** can be used only if you have overloaded the allocation operator with the appropriate arguments. You can use the placement syntax when you want to use and reuse a memory space which you set up once at the beginning of your program. When you use the overloaded **operator new( )** to specify where you want an allocation to be placed, you are responsible for deleting the allocation. Because you call your version of the allocation operator, you cannot depend on the global **::operator delete( )** to do the cleanup. To release memory, you... more (see page 436)
Overloading The Operator delete (see page 436)	The global operators, ::operator delete(), and **::operator delete[]()** cannot be overloaded. However, you can override the default version of each of these operators with your own implementation. Only one instance of the each global delete function can exist in the program. The user-defined operator delete must have a **void** return type and **void*** as its first argument; a second argument of type size_t is optional. A class T can define at most one version of each of T**::operator delete[]()** and T**::operator delete()**. To overload the **delete** operators, use the following prototypes. • void operator delete(void *Type_ptr, [size_t... more (see page 436)
Overloading The Operator new (see page 436)	The global ::operator new() and **::operator new[]()** can be overloaded. Each overloaded instance must have a unique signature. Therefore, multiple instances of a global allocation operator can coexist in a single program. Class-specific memory allocation operators can also be overloaded. The operator **new** can be implemented to provide alternative free storage (heap) memory-management routines, or implemented to accept additional arguments. A user-defined operator **new** must return a **void*** and must have a size_t as its first argument. To overload the **new** operators, use the following prototypes declared in the new.h header file. • void * operator new(size_t Type_size); // For... more (see page 436)
The delete Operator With Arrays (see page 437)	Arrays are deleted by operator delete[](). You must use the syntax **delete []** expr when deleting an array.
Operator new (see page 437)	By default, if there is no overloaded version of new, a request for dynamic memory allocation always uses the global version of new, **::operator new()**. A request for array allocation calls **::operator new[]()**. With class objects of type name, a specific operator called name**::operator new()** or name**::operator new[]()** can be defined. When **new** is applied to class name objects it invokes the appropriate name**::operator new** if it is present; otherwise, the global **::operator new** is used. Only the **operator new()** function will accept an optional initializer. The array allocator version, **operator new[](),** will not accept... more (see page 437)
The Operator new With Arrays (see page 437)	When using the array form of operator new[](), the pointer returned points to the first element of the array. When creating multidimensional arrays with **new**, all array sizes must be supplied (although the leftmost dimension doesn't have to be a compile-time constant):

3.1.3.1.9.1 Handling Errors For The New Operator

By default, **new** throws the bad_alloc exception when a request for memory allocation cannot be satisfied.

You can define a function to be called if the **new** operator fails. To tell the **new** operator about the new-handler function, use set_new_handler and supply a pointer to the new-handler. If you want **new** to return null on failure, you must use set_new_handler(0) .

See Also

new (see page 556)

3.1.3.1.9.2 Operator new Placement Syntax

The placement syntax for **operator new( )** can be used only if you have overloaded the allocation operator with the appropriate arguments. You can use the placement syntax when you want to use and reuse a memory space which you set up once at the beginning of your program.

When you use the overloaded **operator new( )** to specify where you want an allocation to be placed, you are responsible for deleting the allocation. Because you call your version of the allocation operator, you cannot depend on the global **::operator delete( )** to do the cleanup.

To release memory, you make an explicit call on the destructor. This method for cleaning up memory should be used only in special situations and with great care. If you make an explicit call of a destructor before an object that has been constructed on the stack goes out of scope, the destructor will be called again when the stackframe is cleaned up.

See Also

The keyword new (see page 556)

3.1.3.1.9.3 Overloading The Operator delete

The global operators, ::operator delete(), and **::operator delete[]()** cannot be overloaded. However, you can override the default version of each of these operators with your own implementation. Only one instance of the each global delete function can exist in the program.

The user-defined operator delete must have a **void** return type and **void*** as its first argument; a second argument of type size_t is optional. A class T can define at most one version of each of T**::operator delete[]()** and T**::operator delete()**. To overload the **delete** operators, use the following prototypes.

- void operator delete(void *Type_ptr, [size_t Type_size]); // For Non-array
- void operator delete[](size_t Type_ptr, [size_t Type_size]); // For arrays

See Also

The keyword delete (see page 546)

3.1.3.1.9.4 Overloading The Operator new

The global ::operator new() and **::operator new[]()** can be overloaded. Each overloaded instance must have a unique signature. Therefore, multiple instances of a global allocation operator can coexist in a single program.

Class-specific memory allocation operators can also be overloaded. The operator **new** can be implemented to provide alternative free storage (heap) memory-management routines, or implemented to accept additional arguments. A user-defined operator **new** must return a **void*** and must have a size_t as its first argument. To overload the **new** operators, use the following prototypes declared in the new.h header file.

- void * operator new(size_t Type_size); // For Non-array
- void * operator new[](size_t Type_size); // For arrays

The compiler provides Type_size to the **new** operator. Any data type may be substituted for Type_size except function names (although a pointer to function is permitted), class declarations, enumeration declarations, const, volatile.

See Also

The keyword new (see page 556)

3.1.3.1.9.5 The delete Operator With Arrays

Arrays are deleted by operator delete[](). You must use the syntax **delete []** expr when deleting an array.

```
char * p;
void func()
{
   p = new char[10];    //  allocate 10 chars
   delete[] p;          // delete 10 chars
}
```

Early C++ compilers required the array size to be named in the delete expression. In order to handle legacy code, the compiler issues a warning and simply ignores any size that is specified. For example, if the preceding example reads delete[10] p and is compiled, the warning is as follows:

```
Warning: Array size for 'delete' ignored in function func()
```

See Also

The keyword delete (see page 546)

3.1.3.1.9.6 Operator new

By default, if there is no overloaded version of new, a request for dynamic memory allocation always uses the global version of new, **::operator new()**. A request for array allocation calls **::operator new[]()**. With class objects of type name, a specific operator called name**::operator new()** or name**::operator new[]()** can be defined. When **new** is applied to class name objects it invokes the appropriate name**::operator new** if it is present; otherwise, the global **::operator new** is used.

Only the **operator new()** function will accept an optional initializer. The array allocator version, **operator new[](),** will not accept initializers. In the absence of explicit initializers, the object created by new contains unpredictable data (garbage). The objects allocated by **new**, other than arrays, can be initialized with a suitable expression between parentheses:

```
int_ptr = new int(3);
```

Arrays of classes with constructors are initialized with the default constructor. The user-defined **new** operator with customized initialization plays a key role in C++ constructors for class-type objects.

See Also

Overloading The Operator New (see page 436)

The keyword new (see page 556)

3.1.3.1.9.7 The Operator new With Arrays

When using the array form of operator new[](), the pointer returned points to the first element of the array. When creating multidimensional arrays with **new**, all array sizes must be supplied (although the leftmost dimension doesn't have to be a compile-time constant):

```
mat_ptr = new int[3][10][12];    // OK
mat_ptr = new int[n][10][12];    // OK
mat_ptr = new int[3][][12];      // illegal
mat_ptr = new int[][10][12];     // illegal
```

Although the first array dimension can be a variable, all following dimensions must be constants.

This section contains How to Construct A Class Of Complex Vector topics.

Topics

Name	Description
Example Of Overloading Operators (see page 439)	The following example extends the class complex to create complex-type vectors. Several of the most useful operators are overloaded to provide some customary mathematical operations in the usual mathematical syntax. Some of the issues illustrated by the example are: • The default constructor is defined. The default constructor is provided by the compiler only if you have not defined it or any other constructor. • The copy constructor is defined explicitly. Normally, if you have not defined any constructors, the compiler will provide one. You should define the copy constructor if you are overloading the assignment operator. • The assignment operator is overloaded.... more (see page 439)

3.1.3.1.11.1.1 Example Of Overloading Operators

The following example extends the class complex to create complex-type vectors. Several of the most useful operators are overloaded to provide some customary mathematical operations in the usual mathematical syntax.

Some of the issues illustrated by the example are:

- The default constructor is defined. The default constructor is provided by the compiler only if you have not defined it or any other constructor.
- The copy constructor is defined explicitly. Normally, if you have not defined any constructors, the compiler will provide one. You should define the copy constructor if you are overloading the assignment operator.
- The assignment operator is overloaded. If you do not overload the assignment operator, the compiler calls a default assignment operator when required. By overloading assignment of cvector types, you specify exactly the actions to be taken. Note that derived classes cannot inherit the assignment operator.
- The subscript operator is defined as a member function (a requirement when overloading) with a single argument. The **const** version assures the caller that it will not modify its argument—this is useful when copying or assigning. This operator should check that the index value is within range—a good place to implement exception handling.
- The addition operator is defined as a member function. It allows addition only for cvector types. Addition should always check that the operands' sizes are compatible.
- The multiplication operator is declared a **friend**. This lets you define the order of the operands. An attempt to reverse the order of the operands is a compile-time error.
- The stream insertion operator is overloaded to naturally display a cvector. Large objects that don't display well on a limited size screen might require a different display strategy.

Example Source

```
/* HOW TO EXTEND THE complex CLASS AND OVERLOAD THE REQUIRED OPERATORS. */
complexcomplexcomplex
#include <complex>  // This includes iostream
using namespace std;
// COMPLEX VECTORS
template <class T>
class cvector {
   int size;
   complex<T> *data;
public:
   cvector() { size = 0; data = NULL; };
   cvector(int i = 5) : size(i) {    // DEFAULT VECTOR SIZE.
      data = new complex<T>[size];
      for (int j = 0; j < size; j++)
           data[j] = j + (0.1 * j);  // ARBITRARY INITIALIZATION.
```

```
    };
  /* THIS VERSION IS CALLED IN main() */
  complex<T>& operator [](int i) { return data[i]; };
  /* THIS VERSION IS CALLED IN ASSIGNMENT OPERATOR AND COPY THE CONSTRUCTOR */
  const complex<T>& operator [](int i) const { return data[i]; };
  cvector operator +(cvector& A) {  // ADDITION OPERATOR
     cvector result(A.size);  // DO NOT MODIFY THE ORIGINAL
     for (int i = 0; i < size; i++)
         result[i] = data[i] + A.data[i];
     return result;
     };
  /* BECAUSE scalar * vector MULTIPLICATION IS NOT COMMUTATIVE, THE ORDER OF
     THE ELEMENTS MUST BE SPECIFIED. THIS FRIEND OPERATOR FUNCTION WILL ENSURE
     PROPER MULTIPLICATION. */
  friend cvector operator *(T scalar, cvector& A) {
     cvector result(A.size);  // DO NOT MODIFY THE ORIGINAL
     for (int i = 0; i < A.size; i++)
       result.data[i] = scalar * A.data[i];
     return result;
     }
  /* THE STREAM INSERTION OPERATOR. */
  friend ostream& operator <<(ostream& out_data, cvector& C) {
     for (int i = 0; i < C.size; i++)
          out_data << "[" << i << "]=" << C.data[i] << "   ";
     cout << endl;
     return out_data;
     };
  cvector( const cvector &C ) {  // COPY CONSTRUCTOR
     size = C.size;
     data = new complex<T>[size];
     for (int i = 0; i < size; i++)
          data[i] = C[i];
    }
  cvector& operator =(const cvector &C) { // ASSIGNMENT OPERATOR.
     if (this == &C) return *this;
     delete[] data;
     size = C.size;
     data = new complex<T>[size];
     for (int i = 0; i < size; i++)
         data[i] = C[i];
     return *this;
  };
  virtual ~cvector() { delete[] data; }; // DESTRUCTOR
  };
int main(void) { /* A FEW OPERATIONS WITH complex VECTORS. */
  cvector<float> cvector1(4), cvector2(4), result(4);
  // CREATE complex NUMBERS AND ASSIGN THEM TO complex VECTORS
  cvector1[3] = complex<float>(3.3, 102.8);
  cout << "Here is cvector1:" << endl;
  cout << cvector1;
  cvector2[3] = complex<float>(33.3, 81);
  cout << "Here is cvector2:" << endl;
  cout << cvector2;
  result = cvector1 + cvector2;
  cout << "The result of vector addition:" << endl;
  cout << result;
  result = 10 * cvector2;
  cout << "The result of 10 * cvector2:" << endl;
  cout << result;
  return 0;
  }
```

Output

```
Here is cvector1:
[0]=(0, 0)   [1]=(1.1, 0)   [2]=(2.2, 0)   [3]=(3.3, 102.8)
Here is cvector2:
```

```
[0]=(0, 0)   [1]=(1.1, 0)   [2]=(2.2, 0)   [3]=(33.3, 81)
The result of vector addition:
[0]=(0, 0)   [1]=(2.2, 0)   [2]=(4.4, 0)   [3]=(36.6, 183.8)
The result of 10 * cvector2:
[0]=(0, 0)   [1]=(11, 0)   [2]=(22, 0)   [3]=(333, 810)
```

3.1.3.1.11.2 Overloading Operators

C++ lets you redefine the actions of most operators, so that they perform specified functions when used with objects of a particular class. As with overloaded C++ functions in general, the compiler distinguishes the different functions by noting the context of the call: the number and types of the arguments or operands.

All the operators can be overloaded except for:

```
.   .*   ::   ?:
```

The following preprocessing symbols cannot be overloaded.

```
#   ##
```

The =, [ ], ( ), and -> operators can be overloaded only as nonstatic member functions. These operators cannot be overloaded for **enum** types. Any attempt to overload a global version of these operators results in a compile-time error.

The keyword **operator** followed by the operator symbol is called the operator function name; it is used like a normal function name when defining the new (overloaded) action for the operator.

A function operator called with arguments behaves like an operator working on its operands in an expression. The operator function cannot alter the number of arguments or the precedence and associativity rules applying to normal operator use.

3.1.3.1.12 Overloading Operator Functions Overview

This section contains Overloading Operator Functions Overview topics.

Topics

Name	Description
Overloading The Assignment operator = (see page 442)	The assignment operator=( ) can be overloaded by declaring a nonstatic member function. For example,
Overloading Binary Operators (see page 442)	You can overload a binary operator by declaring a nonstatic member function taking one argument, or by declaring a non-member function (usually friend) taking two arguments. If @ represents a binary operator, x@y can be interpreted as either x.operator@(y) or operator@(x,y) depending on the declarations made. If both forms have been declared, standard argument matching is applied to resolve any ambiguity.
Overloading The Class Member Access Operators -> (see page 443)	**Syntax**
Overloading The Function Call Operator ( ) (see page 443)	**Syntax**

Overloading Operator Functions (see page 444)	Operator functions can be called directly, although they are usually invoked indirectly by the use of the overload operator:
Overloaded Operators And Inheritance (see page 444)	With the exception of the assignment function operator =( ), all overloaded operator functions for class X are inherited by classes derived from X, with the standard resolution rules for overloaded functions. If X is a base class for Y, an overloaded operator function for X could possibly be further overloaded for Y.
Overloading The Subscript Operator [] (see page 445)	**Syntax**
Overloading Unary Operators (see page 445)	You can overload a prefix or postfix unary operator by declaring a nonstatic member function taking no arguments, or by declaring a nonmember function taking one argument. If @ represents a unary operator, @x and x@ can both be interpreted as either x.operator@() or operator@(x), depending on the declarations made. If both forms have been declared, standard argument matching is applied to resolve any ambiguity. • Under C++ 2.0, an overloaded operator ++ or -- is used for both prefix and postfix uses of the operator. • With C++ 2.1, when an operator ++ or operator -- is declared as a member... more (see page 445)

3.1.3.1.12.1 Overloading The Assignment operator =

The assignment operator=( ) can be overloaded by declaring a nonstatic member function. For example,

```
class String {
      .
      .
      .
   String& operator = (String& str);
      .
      .
      .
   String (String&);
   ~String();
}
```

This code, with suitable definitions of String::operator =(), allows string assignments str1 = str2 in the usual sense. Unlike the other operator functions, the assignment operator function cannot be inherited by derived classes. If, for any class X, there is no user-defined operator =, the operator = is defined by default as a member-by-member assignment of the members of class X:

```
X& X::operator = (const X& source)
{
   // memberwise assignment
}
```

Overloading The Class Member Access Operators -> (see page 443)

Overloading The Function Call Operator ( ) (see page 443)

Overloading The Subscript Operator [] (see page 445)

3.1.3.1.12.2 Overloading Binary Operators

You can overload a binary operator by declaring a nonstatic member function taking one argument, or by declaring a non-member function (usually friend) taking two arguments. If @ represents a binary operator, x@y can be interpreted as either

x.operator@(y) or operator@(x,y) depending on the declarations made. If both forms have been declared, standard argument matching is applied to resolve any ambiguity.

Overloading The Function Call Operator ( ) (see page 443)

Overloading The Subscript Operator [] (see page 445)

3.1.3.1.12.3 Overloading The Class Member Access Operators ->

Syntax

```
postfix-expression -> primary-expression
```

Description

The expression x->m, where x is a **class** X object, is interpreted as (x.operator->())->m, so that the function **operator->()** must either return a pointer to a class object or return an object of a class for which **operator->** is defined.

The **operator->()** can only be overloaded as a nonstatic member function.

Example Of Overloading Operators (see page 439)

Overloaded Operators And Inheritance (see page 444)

Overloading Binary Operators (see page 442)

Overloading Operator Functions (see page 444)

Overloading The Assignment Operator = (see page 442)

Overloading The Function Call Operator ( ) (see page 443)

Overloading The Subscript Operator [] (see page 445)

3.1.3.1.12.4 Overloading The Function Call Operator ( )

Syntax

```
postfix-expression ( <expression-list> )
```

Description

In its ordinary use as a function call, the postfix-expression must be a function name, or a pointer or reference to a function. When the postfix-expression is used to make a member function call, postfix-expression must be a class member function name or a pointer-to-member expression used to select a class member function. In either case, the postfix-expression is followed by the optional expression-list.

A call X(arg1, arg2), where X is an object class X, is interpreted as X.**operator()**(arg1, arg2).

The function call operator, **operator()()**, can only be overloaded as a nonstatic member function.

Overloading Binary Operators (see page 442)

Overloading Operator Functions (see page 444)

Overloading The Assignment Operator = (see page 442)

Overloading The Class Member Access Operators -> (see page 443)

Overloading The Subscript Operator [] (see page 445)

3.1.3.1.12.5 Overloading Operator Functions

Operator functions can be called directly, although they are usually invoked indirectly by the use of the overload operator:

```
c3 = c1.operator + (c2);   // same as c3 = c1 + c2
```

Apart from new and delete, which have their own rules, an operator function must either be a nonstatic member function or have at least one argument of class type. The operator functions =, ( ), [ ] and -> must be nonstatic member functions.

Enumerations can have overloaded operators. However, the operator functions =, ( ), [ ], and -> cannot be overloaded for enumerations.

Example Of Overloading Operators (see page 439)

Overloaded Operators And Inheritance (see page 444)

Overloading Binary Operators (see page 442)

Overloading The Assignment Operator = (see page 442)

Overloading The Class Member Access Operators -> (see page 443)

Overloading The Function Call Operator ( ) (see page 443)

Overloading The Subscript Operator [] (see page 445)

3.1.3.1.12.6 Overloaded Operators And Inheritance

With the exception of the assignment function operator =( ), all overloaded operator functions for class X are inherited by classes derived from X, with the standard resolution rules for overloaded functions. If X is a base class for Y, an overloaded operator function for X could possibly be further overloaded for Y.

Overloading The Function Call Operator ( ) (see page 443)

Overloading The Subscript Operator [] (see page 445)

3.1.3.1.12.7 Overloading The Subscript Operator []

Syntax

```
postfix-expression [ expression ]
```

Description

The corresponding operator function is operator[]() this can be user-defined for a class X (and any derived classes). The expression X[y], where X is an object of class X, is interpreted as x.operator[](y).

The **operator[]()** can only be overloaded as a nonstatic member function.

Overloading The Class Member Access Operators -> (see page 443)

3.1.3.1.12.8 Overloading Unary Operators

You can overload a prefix or postfix unary operator by declaring a nonstatic member function taking no arguments, or by declaring a nonmember function taking one argument. If @ represents a unary operator, @x and x@ can both be interpreted as either x.operator@() or operator@(x), depending on the declarations made. If both forms have been declared, standard argument matching is applied to resolve any ambiguity.

- Under C++ 2.0, an overloaded operator ++ or -- is used for both prefix and postfix uses of the operator.
- With C++ 2.1, when an operator ++ or operator -- is declared as a member function with no parameters, or as a nonmember function with one parameter, it only overloads the prefix operator ++ or operator --. You can only overload a postfix operator ++ or operator -- by defining it as a member function taking an int parameter or as a nonmember function taking one class and one int parameter.

When only the prefix version of an operator ++ or operator -- is overloaded and the operator is applied to a class object as a postfix operator, the compiler issues a warning. Then it calls the prefix operator, allowing 2.0 code to compile. The preceding example results in the following warnings:

```
Warning: Overloaded prefix 'operator ++' used as a postfix operator in function func()
Warning: Overloaded prefix 'operator --' used as a postfix operator in function func()
```

3.1.3.1.13 Polymorphic Classes

This section contains Polymorphic Class topics.

Topics

Name	Description
Abstract Classes (see page 446)	This section contains Abstract Class topics.
Polymorphic Classes (see page 447)	Classes that provide an identical interface, but can be implemented to serve different specific requirements, are referred to as polymorphic classes. A class is polymorphic if it declares or inherits at least one virtual (or pure virtual) function. The only types that can support polymorphism are **class** and **struct**.
Virtual Functions (see page 447)	This section contains Virtual Function topics.

3.1.3.1.13.1 Abstract Classes

This section contains Abstract Class topics.

Topics

Name	Description
Abstract Classes (see page 446)	An abstract class is a class with at least one pure **virtual** function. A **virtual** function is specified as pure by setting it equal to zero. An abstract class can be used only as a base class for other classes. No objects of an abstract class can be created. An abstract class cannot be used as an argument type or as a function return type. However, you can declare pointers to an abstract class. References to an abstract class are allowed, provided that a temporary object is not needed in the initialization. For example,

3.1.3.1.13.1.1 Abstract Classes

An abstract class is a class with at least one pure **virtual** function. A **virtual** function is specified as pure by setting it equal to zero.

An abstract class can be used only as a base class for other classes. No objects of an abstract class can be created. An abstract class cannot be used as an argument type or as a function return type. However, you can declare pointers to an abstract class. References to an abstract class are allowed, provided that a temporary object is not needed in the initialization. For example,

```
class shape {       // abstract class
   point center;
.
.
.
public:
   where() { return center; }
   move(point p) { center = p; draw(); }
   virtual void rotate(int) = 0; // pure virtual function
   virtual void draw() = 0;      // pure virtual function
   virtual void hilite() = 0;    // pure virtual function
.
.
.
}
shape x;// ERROR: attempt to create an object of an abstract class
   shape* sptr;// pointer to abstract class is OK
   shape f();// ERROR: abstract class cannot be a return type
int g(shape s);// ERROR: abstract class cannot be a function argument type
shape& h(shape&);// reference to abstract class as return
 // value or function argument is OK
```

Suppose that D is a derived class with the abstract class B as its immediate base class. Then for each pure virtual function pvf in B, if D doesn't provide a definition for pvf, pvf becomes a pure member function of D, and D will also be an abstract class.

For example, using the class shape previously outlined,

```
class circle : public shape {// circle derived from abstract class
   int radius;// private
public:
   void rotate(int) { }// virtual function defined: no action
            //  to rotate a circle
   void draw();      // circle::draw must be defined somewhere
}
```

Member functions can be called from a constructor of an abstract class, but calling a pure virtual function directly or indirectly from such a constructor provokes a runtime error.

Dynamic Functions (see page 447)

Abstract Classes (see page 446)

3.1.3.1.13.3 Virtual Functions

This section contains Virtual Function topics.

Topics

Name	Description
Dynamic Functions (see page 447)	**dynamic** functions are allowed for classes derived from TObject. Dynamic functions are similar to virtual functions except for the way they are stored in the virtual tables. Virtual functions occupy a slot in the virtual table in the object they are defined in, and in the virtual table of every descendant of that object. Dynamic functions occupy a slot in every object that defines them, not in any descendants. That is, dynamic functions are virtual functions stored in sparse virtual tables. If you call a dynamic function, and that function is not defined in your object, the virtual tables of... more (see page 447)
Virtual Functions (see page 449)	**virtual** functions allow derived classes to provide different versions of a base class function. You can use the **virtual** keyword to declare a **virtual** function in a base class. By declaring the function prototype in the usual way and then prefixing the declaration with the **virtual** keyword. To declare a pure function (which automatically declares an abstract class), prefix the prototype with the **virtual** keyword, and set the function equal to zero.

3.1.3.1.13.3.1 Dynamic Functions

dynamic functions are allowed for classes derived from TObject. Dynamic functions are similar to virtual functions except for the way they are stored in the virtual tables. Virtual functions occupy a slot in the virtual table in the object they are defined in, and in the virtual table of every descendant of that object. Dynamic functions occupy a slot in every object that defines them, not in any descendants. That is, dynamic functions are virtual functions stored in sparse virtual tables. If you call a dynamic function, and that function is not defined in your object, the virtual tables of its ancestors are searched until the function is found.

Therefore, dynamic functions reduces the size of your virtual tables at the expense of a delay at runtime to look up the address of the functions.

Because dynamic functions are available only in classes derived from TObject, you will get an error if you use them in a regular class. For example:

```
class dynfunc {
int __declspec(dynamic) bar() { return 5; }
};
```

gives the syntax error, “Error: Storage class 'dynamic' is not allowed here.” But, the following code compiles.

```
#include <clxvcl.h>
#include <stdio.h>
class __declspec(delphiclass) func1 : public TObject {
public:
func1() {}
int virtual virtbar() { return 5; }
int __declspec(dynamic) dynbar() { return 5; }
};
class __declspec(delphiclass) func2 : public func1 {
public:
func2() {}
};
class __declspec(delphiclass) func3 : public func2 {
public:
func3() {}
int virtbar() { return 10; }
int dynbar() { return 10; }
};
int main()
{
func3 * Func3 = new func3;
func1 * Func1 = Func3;
printf("func3->dynbar: %d\n", Func3->dynbar());
printf("func3->virtbar: %d\n", Func3->virtbar());
printf("func1->dynbar: %d\n", Func1->dynbar());
printf("func1->virtbar: %d\n", Func1->virtbar());
delete Func3;
func2 * Func2 = new func2;
printf("func2->dynbar: %d\n", Func2->dynbar());
printf("func2->virtbar: %d\n", Func2->virtbar());
delete Func2;
return 0;
}
```

Dynamic attribute is inherited

Since dynamic functions are just like virtual functions, the dynamic attribute is automatically inherited. You can verify this by running the above example. When you generate assembly output with "bcc32 -S" you can examine the virtual tables of func1, func2, and func3, and you'll see how func2 has NO entry for dynbar, but it does have an entry for virtbar. Still, you can call dynbar in the func2 object:

Output:

```
func3->dynbar: 10
func3->virtbar: 10
func1->dynbar: 10
func1->virtbar: 10
func2->dynbar: 5
func2->virtbar: 5
```

Dynamic functions cannot be made virtual, and vice-versa

You cannot redeclare a virtual function to be dynamic; likewise, you cannot redeclare a dynamic function to be virtual. The following example gives errors:

```
#include <clxvcl.h>
#include <stdio.h>
class __declspec(delphiclass) foo1 : public TObject {
public:
foo1() {}
int virtual virtbar() { return 5; }
int __declspec(dynamic) dynbar() { return 5; }
};
class __declspec(delphiclass) foo2 : public foo1 {
public:
foo2() {}
int __declspec(dynamic) virtbar() { return 10; }
int virtual dynbar() { return 10; }
};
Error : Cannot override a virtual with a dynamic function
Error : Cannot override a dynamic with a virtual function
```

Virtual Functions (see page 449)

Dynamic Functions

Abstract Classes (see page 446)

3.1.3.1.13.3.2 Virtual Functions

virtual functions allow derived classes to provide different versions of a base class function. You can use the **virtual** keyword to declare a **virtual** function in a base class. By declaring the function prototype in the usual way and then prefixing the declaration with the **virtual** keyword. To declare a pure function (which automatically declares an abstract class), prefix the prototype with the **virtual** keyword, and set the function equal to zero.

```
virtual int funct1(void);       // A virtual function declaration.
virtual int funct2(void) = 0;   // A pure function declaration.
```

A function declaration cannot provide both a pure-specifier and a definition.

Example

```
struct C {
    virtual void f() { } = 0; // ill-formed
};
```

The only legal syntax to provide a body is:

```
struct TheClass
{
  virtual void funct3(void) = 0;
};
virtual void TheClass::funct3(void)
{
   // Some code here.
};
```

Note: See Abstract classesAbstractClasses for a discussion of pure virtual functions.

When you declare **virtual** functions, keep these guidelines in mind:

- They can be member functions only.
- They can be declared a **friend** of another class.
- They cannot be a static member.

A **virtual** function does not need to be redefined in a derived class. You can supply one definition in the base class so that all calls will access the base function.

To redefine a **virtual** function in any derived class, the number and type of arguments must be the same in the base class declaration and in the derived class declaration. (The case for redefined **virtual** functions differing only in return type is discussed below.) A redefined function is said to override the base class function.

You can also declare the functions int Base::Fun(int) and int Derived::Fun(int) even when they are not virtual. In such a case, int Derived::Fun(int) is said to hide any other versions of Fun(int) that exist in any base classes. In addition, if class Derived defines other versions of Fun(), (that is, versions of Fun() with different signatures) such versions are said to be overloaded versions of Fun().

Virtual function return types

Generally, when redefining a **virtual** function, you cannot change just the function return type. To redefine a **virtual** function, the new definition (in some derived class) must exactly match the return type and formal parameters of the initial declaration. If two functions with the same name have different formal parameters, C++ considers them different, and the **virtual** function mechanism is ignored.

However, for certain virtual functions in a base class, their overriding version in a derived class can have a return type that is different from the overridden function. This is possible only when both of the following conditions are met:

- The overridden **virtual** function returns a pointer or reference to the base class.
- The overriding function returns a pointer or reference to the derived class.

If a base class B and class D (derived publicly from B) each contain a **virtual** function vf, then if vf is called for an object d of D, the call made is D::vf(), even when the access is via a pointer or reference to B. For example,

```
struct X {};// Base class.
struct Y : X {};// Derived class.
struct B {
   virtual void vf1();
   virtual void vf2();
   virtual void vf3();
   void f();
   virtual X* pf();// Return type is a pointer to base. This can
  //  be overridden.
};
class D : public B {
public:
   virtual void vf1();// Virtual specifier is legal but redundant.
   void vf2(int);// Not virtual, since it's using a different
 //  arg list. This hides B::vf2().
// char vf3();// Illegal: return-type-only change!
   void f();
   Y*   pf();// Overriding function differs only
   //  in return type. Returns a pointer to
 //  the derived class.
};
void extf()
{
   D d;// Instantiate D
   B* bp = &d;// Standard conversion from D* to B*
  // Initialize bp with the table of functions
// provided for object d. If there is no entry for a
  // function in the d-table, use the function
     //  in the B-table.
   bp->vf1();  // Calls D::vf1
   bp->vf2();  // Calls B::vf2 since D's vf2 has different args
   bp->f();    // Calls B::f (not virtual)
   X* xptr = bp->pf();// Calls D::pf() and converts the result
   //  to a pointer to X.
   D* dptr = &d;
   Y* yptr = dptr->pf();// Calls D::pf() and initializes yptr.
   //  No further conversion is done.
}
```

The overriding function vf1 in D is automatically **virtual**. The **virtual** specifier can be used with an overriding function declaration in the derived class. If other classes will be derived from D, the **virtual** keyword is required. If no further classes will be derived

from D, the use of **virtual** is redundant.

The interpretation of a **virtual** function call depends on the type of the object it is called for; with nonvirtual function calls, the interpretation depends only on the type of the pointer or reference denoting the object it is called for.

virtual functions exact a price for their versatility: each object in the derived class needs to carry a pointer to a table of functions in order to select the correct one at runtime (late binding).

Abstract Classes (see page 446)

3.1.3.1.14 Referencing

This section contains Typeid Operator topics.

Topics

Name	Description
Reference Arguments (see page 451)	The reference declarator can also be used to declare reference type parameters within a function:
Referencing (see page 452)	In the C programming language, you can pass arguments only by value. In C++, you can pass arguments by value or by reference. C++ reference types, closely related to pointer types, create aliases for objects. See the following topics for a discussion of referencing. **Note:** C++ specific pointer referencing and dereferencing is discussed in C++ specific operators (see page 590).
Simple References (see page 453)	The reference declarator can be used to declare references outside functions:

3.1.3.1.14.1 Reference Arguments

The reference declarator can also be used to declare reference type parameters within a function:

```
void func1 (int i);
void func2 (int &ir);   // ir is type "reference to int"
    .
    .
    .
int sum = 3;
func1(sum);             // sum passed by value
func2(sum);             // sum passed by reference
```

The sum argument passed by reference can be changed directly by func2. On the other hand, func1 gets a copy of the sum argument (passed by value), so sum itself cannot be altered by func1.

When an actual argument x is passed by value, the matching formal argument in the function receives a copy of x. Any changes to this copy within the function body are not reflected in the value of x outside the scope of the function. Of course, the function can return a value that could be used later to change x, but the function cannot directly alter a parameter passed by value.

In C, changing the value of a function parameter outside the scope of the function requires that you pass the address of the parameter. The address is passed by value, thus changing the contents of the address effects the value of the parameter outside the scope of the function.

Even if the function does not need to change the value of a parameter, it is still useful to pass the address (or a reference) to a function. This is especially true if the parameter is a large data structure or object. Passing an object directly to a function necessitates copying the entire object.

Compare the three implementations of the function treble:

Implementation 1

```
int treble_1(int n)
{
   return 3 * n;
}
  .
  .
  .
int x, i = 4;
x = treble_1(i);  // x now = 12, i = 4
  .
  .
  .
```

Implementation 2

```
void treble_2(int* np)
{
   *np = (*np) * 3;
}
  .
  .
  .
treble_2(&i);    // i now = 2
```

Implementation 3

```
void treble_3(int& n)   // n is a reference type
{
   n = n * 3;
}
  .
  .
  .
treble_3(i);             // i now = 36
```

The formal argument declaration **type**& t establishes t as type “reference to type.” So, when treble_3 is called with the real argument i, i is used to initialize the formal reference argument n. n therefore acts as an alias for i, so n = n*3 also assigns 3 * i to i.

If the initializer is a constant or an object of a different type than the reference type, creates a temporary object for which the reference acts as an alias:

```
int& ir = 6;   /* temporary int object created, aliased by ir, gets value 6 */
float f;
int& ir2 = f;  /* creates temporary int object aliased by ir2; f converted
                  before assignment */
ir2 = 2.0      // ir2 now = 2, but f is unchanged
```

The automatic creation of temporary objects permits the conversion of reference types when formal and actual arguments have different (but assignment-compatible) types. When passing by value, of course, there are fewer conversion problems, since the copy of the actual argument can be physically changed before assignment to the formal argument.

See Also

Referencing (see page 452)

Simple References (see page 453)

3.1.3.1.14.2 Referencing

In the C programming language, you can pass arguments only by value. In C++, you can pass arguments by value or by reference. C++ reference types, closely related to pointer types, create aliases for objects. See the following topics for a discussion of referencing.

Note: C++ specific pointer referencing and dereferencing is discussed in C++ specific operators (see page 590).

See Also

Simple References (see page 453)

Reference Arguments (see page 451)

Reference/Dereference Operators (see page 658)

3.1.3.1.14.3 Simple References

The reference declarator can be used to declare references outside functions:

```
int  i  = 0;
int &ir = i;   // ir is an alias for i
ir = 2;        // same effect as i = 2
```

This creates the lvalue ir as an alias for i, provided the initializer is the same type as the reference. Any operations on ir have precisely the same effect as operations on i. For example, ir = 2 assigns 2 to i, and &ir returns the address of i.

Referencing (see page 452)

Reference Arguments (see page 451)

3.1.3.1.15 Run-time Type Identification (RTTI)

This section contains Run-time Type Identification (RTTI) topics.

Topics

Name	Description
Runtime Type Identification (RTTI) Overview (see page 453)	Runtime type identification (RTTI) lets you write portable code that can determine the actual type of a data object at runtime even when the code has access only to a pointer or reference to that object. This makes it possible, for example, to convert a pointer to a virtual base class into a pointer to the derived type of the actual object. Use the dynamic_cast operator to make runtime casts. The RTTI mechanism also lets you check whether an object is of some particular type and whether two objects are of the same type. You can do this with typeid... more (see page 453)
The Typeid Operator (see page 454)	This section contains Typeid Operator topics.

3.1.3.1.15.1 Runtime Type Identification (RTTI) Overview

Runtime type identification (RTTI) lets you write portable code that can determine the actual type of a data object at runtime even when the code has access only to a pointer or reference to that object. This makes it possible, for example, to convert a pointer to a virtual base class into a pointer to the derived type of the actual object. Use the dynamic_cast operator to make runtime casts.

The RTTI mechanism also lets you check whether an object is of some particular type and whether two objects are of the same type. You can do this with typeid operator, which determines the actual type of its argument and returns a reference to an object of type **const** type_info, which describes that type.

You can also use a type name as the argument to **typeid**, and **typeid** will return a reference to a **const** type_info object for that type. The class type_info provides an **operator==** and an **operator!=** that you can use to determine whether two objects are of the same type. Class type_info also provides a member function name that returns a pointer to a character string that holds the name of the type.

__rtti (see page 528)

The Typeid Operator (see page 454)

3.1.3.1.15.2 The Typeid Operator

This section contains Typeid Operator topics.

Topics

Name	Description
Runtime Type Identification And Destructors (see page 454)	When destructor cleanup is enabled, a pointer to a class with a virtual destructor can't be deleted if that class is not compiled with runtime type identification enabled. The runtime type identification and destructor cleanup options are on by default. They can be disabled from the C++ page of the Project Options dialog box, or by using the **-xd-** and **-RT-** command-line options. **Example**

3.1.3.1.15.2.1 Runtime Type Identification And Destructors

When destructor cleanup is enabled, a pointer to a class with a virtual destructor can't be deleted if that class is not compiled with runtime type identification enabled. The runtime type identification and destructor cleanup options are on by default. They can be disabled from the C++ page of the Project Options dialog box, or by using the **-xd-** and **-RT-** command-line options.

Example

```
class Alpha {
public:
   virtual ~Alpha( ) { }
};
void func( Alpha *Aptr ) {
   delete Aptr;         // Error.  Alpha is not a polymorphic class type
}
```

3.1.3.1.16 The Scope Resolution Operator

This section contains Scope Resolution Operator topics.

Topics

Name	Description
Scope Resolution Operator :: (see page 454)	The scope access (or resolution) operator **::** (two colons) lets you access a global (or file duration) member name even if it is hidden by a local redeclaration of that name. You can use a global identifier by prefixing it with the scope resolution operator. You can access a nested member name by specifying the class name and using the scope resolution operator. Therefore, Alpha::func( ) and Beta::func( ) are two different functions.

3.1.3.1.16.1 Scope Resolution Operator ::

The scope access (or resolution) operator **::** (two colons) lets you access a global (or file duration) member name even if it is hidden by a local redeclaration of that name. You can use a global identifier by prefixing it with the scope resolution operator. You can access a nested member name by specifying the class name and using the scope resolution operator. Therefore, Alpha::func( ) and Beta::func( ) are two different functions.

3.1.3.1.17 Stricter C++ Compiler (C++Builder 2007)

To more closely obey the rules of the C++ ANSI Standard, the C++ compiler shipping with C++Builder 2007 is stricter than previous versions. Code that did not generate errors in earlier versions of C++Builder might fail to compile beginning with

C++Builder 2007.

This section lists some of the common areas where the compiler is stricter. Each case is illustrated with an example showing the problem and how to update the code to compile with C++Builder 2007. Note that there are often many ways to bring offending code up to date. The appropriate method depends on the intent of the original code.

Topics

Name	Description
Stricter C++ Compiler: Binding of References and Qualifiers (see page 455)	There are many constructs that now generate error messages from the CodeGear C++ compiler included with C++Builder 2007 and newer releases. The rules governing this behavior are described in section 8.5.3 of the 2003 C++ ANSI standard. The rules can be divided into the following categories (with the compiler switch that overrides this behavior): • Binding a non-const lvalue to to non-const reference. (Use the compiler switch **-Vbr** to allow this.) • Binding a temporary to a non-const reference. (Use the compiler switch **-Vbr** to allow this.) • Binding of const or volatile objects to non-const or non-volatile methods repectively. (Use the compiler... more (see page 455)
Stricter C++ Compiler: String Literals Are Now Constants (see page 457)	String literals are now considered to be of type 'const char[]' by default. This, combined with the stricter qualification binding of const values and types, can generate error messages in code that compiled before. You might enable the **-Vbs** switch to revert string literals to non-const. However, CodeGear recommends that you update the code instead. Note that the change in the type of string literals can also change how the compiler resolves calls to overloaded methods. The following example illustrates this:
Stricter C++ Compiler: Template Changes (see page 457)	The C++ compiler no longer allows an explicit template without the 'template <>' prefix. Use the compiler switch **-Vbe** to allow this. The following example shows this:
Stricter C++ Compiler: Function Overload Resolution (see page 458)	One of the areas where the C++Builder 2007 compiler differs the most from the previous versions is in overload resolution, which includes the detection of ambiguity. The compiler now better conforms to the rules in section 13.3 of the 2003 C++ ANSI Standard. Several constructs that were previously allowed might now be reported as ambiguous or no match found, requiring that you modify code to clarify its intent. The compiler option **-Vbo** reverts to the old behavior, not enforcing the new stricter behavior. However, not all compiler changes can be controlled by this switch, so CodeGear recommends that you update... more (see page 458)
Stricter C++ Compiler: Initialization and Conversion (see page 459)	The compiler now obeys the rules of 8.5.1 and 13.3.1 of the 2003 C++ ANSI Standard for initialization and conversion: • Direct initialization now requires initialization by a constructor and no longer picks a user conversion sequence. • Copy initialization for objects of the same or derived type now requires a constructor call. • Copy initialization for objects of the different types no longer prefers user conversion over construction. If the compiler finds a suitable user conversion, it now continues to look for (possibly ambiguous) converting constructors. If the chosen conversion function is a converting constructor, the call initializes a temporary of the... more (see page 459)

3.1.3.1.17.1 Stricter C++ Compiler: Binding of References and Qualifiers

There are many constructs that now generate error messages from the CodeGear C++ compiler included with C++Builder 2007

and newer releases. The rules governing this behavior are described in section 8.5.3 of the 2003 C++ ANSI standard.

The rules can be divided into the following categories (with the compiler switch that overrides this behavior):

- Binding a non-const lvalue to to non-const reference. (Use the compiler switch **-Vbr** to allow this.)
- Binding a temporary to a non-const reference. (Use the compiler switch **-Vbr** to allow this.)
- Binding of const or volatile objects to non-const or non-volatile methods repectively. (Use the compiler switch **-Vbn** to allow this.)

Previous versions of the Borland C++ compilers allowed various forms of binding to non-const reference parameters. In the following example, for instance, one was allowed to simply cast the **psize** parameter:

```
int takesLongRef(long& l);

  int takesUnsignedPtr(unsigned long* psize) {

     return takesLongRef((long)*psize);
  }
```

With C++Builder2007, the above code generates these errors:

```
Error E2357 test.cpp 3: Reference initialized with 'long', needs lvalue of type 'long' in
function takesUnsignedPtr(unsigned long *)
Error E2342 test.cpp 3: Type mismatch in parameter 'l' (wanted 'long &', got 'long') in
function takesUnsignedPtr(unsigned long *)
```

To remedy this, you can cast **psize** before dereferencing, as in:

```
int takesLongRef(long& l);
int takesUnsignedPtr(unsigned long* psize) {     return takesLongRef(*reinterpret_cast
<long*>(psize));   }
```

Be aware of cases that involve temporaries in unobvious ways. For example, some binary operators imply a temporary:

```
enum { zero, one, two } num;
num |= two; // Not allowed
num = num | two; // OK
```

Another case that involves temporaries in an unobvious way is the return value of a property. The following example illustrates code that compiled with previous versions of the compiler:

```
#include <vcl.h>

class TTest {
   WideString FData ;
public:
   __property WideString Data = {read = FData };
};

void Func(WideString& wref);

void test() {
   TTest t;
   Func(t.Data);
}
```

With C++Builder 2007, the above generates two errors:

```
Error E2357 test.cpp 14: Reference initialized with 'const WideString', needs lvalue of type
'WideString' in function test()
Error E2342 test.cpp 14: Type mismatch in parameter 'wref' (wanted 'WideString &', got
'WideString') in function test()
```

You can fix this by changing the reference to a **const** reference, as in:

```
void Func(const WideString& wref);
```

Here is an example of trying to bind a const object to a non-const method:

```
struct X {
   void foo();
};
const X x;
x.foo(); //error
```

Reconcile Error Dialog: Solving Problems

The temporaries and references issue referred to above is encountered in code generated by previous versions of the Reconcile Error Dialog Wizard.

To remedy this, look for the **VarToAnsiStr** method:

```
AnsiString VarToAnsiStr (Variant &V TFieldType DataType)
```

and change it to take a **const Variant&**, as in:

```
AnsiString VarToAnsiStr (const Variant &V, TFieldType DataType)
```

String Literals Are Now Constants (see page 457)

Template Changes (see page 457)

Function Overload Resolution (see page 458)

Initialization and Conversion (see page 459)

3.1.3.1.17.2 Stricter C++ Compiler: String Literals Are Now Constants

String literals are now considered to be of type 'const char[]' by default. This, combined with the stricter qualification binding of const values and types, can generate error messages in code that compiled before.

You might enable the **-Vbs** switch to revert string literals to non-const. However, CodeGear recommends that you update the code instead.

Note that the change in the type of string literals can also change how the compiler resolves calls to overloaded methods. The following example illustrates this:

```
void foo(char *);
 void foo(const char *);
 foo("string"); // New Compiler picks foo(const char *)
```

With C++Builder2007, the above code generates these errors:

Binding of References and Qualifiers (see page 455)

Template Changes (see page 457)

Function Overload Resolution (see page 458)

Initialization and Conversion (see page 459)

3.1.3.1.17.3 Stricter C++ Compiler: Template Changes

The C++ compiler no longer allows an explicit template without the 'template <>' prefix. Use the compiler switch **-Vbe** to allow this. The following example shows this:

```
template <class>
class foo {
 foo();
```

```
};
foo<int>::foo();//Error
template<> foo<int>::foo();//OK
```

Also, the C++ compiler no longer allows explicit template specialization within a class. Use the compiler switch **-Vbx** to allow this. For example, the following generates an error:

```
struct S {};
  struct SP
  {
    template <typename> void foo(const T &) {}
    template <> void foo(const S &) {} // Error
  };

  template <> void SP::foo(const S &) {} //OK
```

Initialization and Conversion (see page 459)

3.1.3.1.17.4 Stricter C++ Compiler: Function Overload Resolution

One of the areas where the C++Builder 2007 compiler differs the most from the previous versions is in overload resolution, which includes the detection of ambiguity. The compiler now better conforms to the rules in section 13.3 of the 2003 C++ ANSI Standard. Several constructs that were previously allowed might now be reported as ambiguous or no match found, requiring that you modify code to clarify its intent.

The compiler option **-Vbo** reverts to the old behavior, not enforcing the new stricter behavior. However, not all compiler changes can be controlled by this switch, so CodeGear recommends that you update the code instead.

The following is an example of an ambiguity that was permitted by the previous compiler:

```
class X{};
  void foo(X);
  void foo(const X&);
  void ambig() {
    X x;
    foo(x); //error-ambiguous-the previous compiler chose 'void foo(x)'
  }
```

std::abs Ambiguity

The standard **abs** function might also generate an ambiguity message when invoked with a parameter that does not exactly match the types expected by the various overloaded versions of abs. Here is an example:

```
#include <limits>bool test(long l) {   return std::abs(l)> 0;}
```

The code above generates an error and a warning:

```
Error E2015 test.cpp 5: Ambiguity between 'std::abs(int) at C:\dev\tp\sc\include\math.h:208'
and 'std::abs(long double) at C:\dev\tp\sc\include\math.h:275' in function test(long)
Warning W8057 test.cpp 6: Parameter 'l' is never used in function test(long)
```

To fix this, cast to the type of the overload you want to invoke. For example:

```
  #include <limits>bool test(long l) {   return std::abs(static_cast<int>(l)) > 0;}
```

String Literals Are Now Constants (see page 457)

Template Changes (see page 457)

Initialization and Conversion (see page 459)

3.1.3.1.17.5 Stricter C++ Compiler: Initialization and Conversion

The compiler now obeys the rules of 8.5.1 and 13.3.1 of the 2003 C++ ANSI Standard for initialization and conversion:

- Direct initialization now requires initialization by a constructor and no longer picks a user conversion sequence.
- Copy initialization for objects of the same or derived type now requires a constructor call.
- Copy initialization for objects of the different types no longer prefers user conversion over construction. If the compiler finds a suitable user conversion, it now continues to look for (possibly ambiguous) converting constructors. If the chosen conversion function is a converting constructor, the call initializes a temporary of the destination type. The result of the call (which is the temporary for the constructor case) is then used to directinitialize the object. Use the compiler switch **-Vbo** to revert to the previous behavior.
- For an explicit cast, the compiler now performs direct initialization on a temporary.

This example illustrates the new behavior:

```
// In this example, dst is destination type and src is source type    class A { };    class V
{    public:      V() { };      V( const V & ) { }      V( const A & ) { }    };G g; V v;
  // direct initialization
  // ==> constructors are considered.
  V v9(g);
  // Both of these statements previously compiled but now get the error:
  // Error E2015: Ambiguity between 'V::V(const V &)' and 'V::V(const A &)'

  // casts
  // (V)g is treated as V tmp(g) which is direct initialization of 'tmp'
  // ==> constructors are considered.
  (V)g;
  static_cast<V> (g);
  // Both of these statements previously compiled but now get the error:
  // Error E2015: Ambiguity between 'V::V(const V &)' and 'V::V(const A &)'

  // copy initialization with dst=V src=G
  // ==> user-defined conversion sequences are considered.
  V v4 = g;
  V v5 = G();
  // Both of these statements now compile but previously got the error:
  // Error E2015: Ambiguity between 'V::V(const A &)' and 'V::V(const V &)'

  // copy initialization with dst=V src=V
  // ==> converting constructors of V are considered.
  V v6 = (V)g;
  V v7 = V(g);
  // Both of these statements compiled previously but now get the error:
  // Error E2015: Ambiguity between 'V::V(const V &)' and 'V::V(const A &)'
```

Conversion via User-Defined Operators

The new C++Builder 2007 compiler often reports ambiguities for conversions that involve user-defined operators. An example is shown below:

```
class AnsiString   {   public:     bool operator ==(const AnsiString& other);
AnsiString(const wchar_t* src);   };
```

```
class Variant   {   public:     operator AnsiString() const;operator wchar_t*() const;
bool operator ==(const AnsiString& rhs) const     { return static_cast<AnsiString>(*this) ==
rhs;}
```

C++Builder users might notice that the above is a stripped down version of the VCL AnsiString and Variant classes. Previous versions of the compiler invoked the 'Variant' 'operator AnsiString() const' for 'static_cast<AnsiString>(*this)', while C++Builder 2007 uses 'conversion via constructor'. Since the Variant can be converted to multiple types for which there are AnsiString constructors, the compiler generates an ambiguity error.

To correct this ambiguity error, you must eliminate the cast as in:

```
 bool operator ==(const AnsiString& rhs) const
  { return (*this) == rhs;}
```

You can also be explicit about the operator:

```
bool operator ==(const AnsiString& rhs) const
  { return this->operator AnsiString() == rhs; }
```

Variant/OleVariant/AnsiString/WideString/TDateTime

The issue described above with a user-defined conversion operator vs. conversion via constructor might be encountered in several constructs involving the VCL classes Variant, OleVariant, AnsiString, WideString, TDateTime, Currency, and so forth.

The following table lists constructs that now generate error messages and the updated syntax.

Previous Construct	Updated Construct	Notes
AnsiString test(OleVariant v) { AnsiString ret = (AnsiString) v; return ret; }	AnsiString test(OleVariant v) { AnsiString ret = /*(AnsiString)*/ v; return ret; }	Do not cast RHS when relying on conversion operator in an assignment.
WideString test(OleVariant v) { WideString w(v); return w; }	WideString test(OleVariant v) { WideString w = v; return w; }	Use Copy Initialization instead of the more direct constructor.

The underlying compiler change for the errors described above is related to the way the compiler now handles initialization and conversion.

3.1.3.1.18 Templates

This section contains Template topics.

Topics

Name	Description
Template Body Parsing (see page 461)	Earlier versions of the compiler didn't check the syntax of a template body unless the template was instantiated. A template body is now parsed immediately when seen like every other declaration.

Using Templates (see page 462)	Templates, also called generics or parameterized types, let you construct a family of related functions or classes. These topics introduce the basic concept of templates: Exporting and importing templates (see page 432) Template Body Parsing (see page 461) Function Templates (see page 433) Class Templates (see page 412) Implicit and Explicit Template Functions (see page 434) Template Compiler Switches (see page 414) The Keyword template (see page 568)

3.1.3.1.18.1 Template Body Parsing

Earlier versions of the compiler didn't check the syntax of a template body unless the template was instantiated. A template body is now parsed immediately when seen like every other declaration.

```
template <class T> class X : T
{
  Int  j;  // Error: Type name expected in template X<T>
};
```

Let's assume that Int hasn't yet been defined. This means that Int must be a member of the template argument T. But it also might just be a typing error and should be **int** instead of Int. Because the compiler can't guess the right meaning it issues an error message.

If you want to access types defined by a template argument you should use a **typedef** to make your intention clear to the compiler:

```
template <class T> class X : T
{
  typedef  typename T::Int  Int;
  Int  j;
};
```

You cannot just write

```
   typedef   T::Int;
```

as in earlier versions of the compiler. Not giving the **typedef** name was acceptable, but this now causes an error message.

All other templates mentioned inside the template body are declared or defined at that point. Therefore, the following example is ill-formed and will not compile:

```
template <class T> class  X
{
  void f(NotYetDefindedTemplate<T> x);
};
```

All template definitions must end with a semicolon. Earlier versions of the compiler did not complain if the semicolon was missing.

3.1.3.1.19 C++0x Features (C++Builder 2009)

C++Builder 2009 implements a number of the new features proposed in the C++0x standard. This section lists and describes these C++0x features. You can view the Working Paper draft that was used to guide the implementation of these features at Draft Working Paper. You can view a summary of the working group papers at Summary of Working Group Papers.

Topics

Name	Description
alignof Operator (C++0x) (see page 463)	The C++0x standard includes the **alignof** keyword and operator, which tells you the alignment of a type. To get the alignment of a type, use the following syntax:
Type Trait Functions (C++0x) (see page 463)	This section contains Type Trait Functions help topics.
Attributes noreturn and final (C++0x) (see page 492)	The C++0x standard includes the addition of attributes that might be applied to the declaration of a class, a general function, a constructor, an array, and so forth. C++Builder 2009 implements two attributes: **noreturn** and **final**. Attributes are set off in the code by double brackets, such as `[[noreturn]]`.
Explicit Conversion Operators (C++0x) (see page 493)	C++Builder 2009 includes support for explicit conversion operators, one of the features in the C++0x standard. You can now apply the function specifier **explicit** in the definition of a user-defined conversion operator. Previously, explicit constructors (including copy constructors) were added to the language in order to prevent unintended conversions being implicitly called by the compiler. Now explicit conversion operators have been added to provide the same control over unintended conversion calls. . Conversion functions declared as explicit work in the same contexts as explicit constructors (that is, direct-initialization, explicit type conversion). Explicit conversion operators produce compiler diagnostics in the same... more (see page 493)
extern Templates (C++0x) (see page 494)	C++Builder 2009 includes the use of **extern** templates, which allow you to define templates that are not instantiated in a translation unit. Using **extern** templates thus reduces both compilation time and the size of the compiled module. This feature is part of the new C++0x standard.
Forward Declaration of Enums (C++0x) (see page 495)	C++Builder 2009 introduces forward declaration of enums. You can declare an enumeration without providing a list of enumerators. Such declarations would not be definitions and can be provided only for enumerations with fixed underlying types. An enumeration can then be re-declared, possibly providing the missing list of enumerators, but the re-declaration must match the previous declaration. This feature is one of the C++0x features added to C++Builder 2009.
rvalue References (C++0x) (see page 495)	C++Builder 2009 includes the use of rvalue references, which allow creating a reference to temporaries. Also, rvalue references avoid unnecessary copying and make possible perfect forwarding functions. This feature is one of the C++0x features.

Static Assertions (C++0x) (see page 498)	The **static_assert** keyword is used to test assertions at compile time. This is one of the C++0x features added to C++Builder 2009. This keyword operates differently than the macro **assert**, which raises assertions at run time. The keyword **static_assert** also differs from the preprocessor directive **#error**, which operates during preprocessing and simply emits a message.
Strongly Typed Enums (C++0x) (see page 498)	C++Builder 2009 introduces scoped enums. In addition, existing enums are extended with underlying type and explicit scoping. This feature is one of the C++0x features added to C++Builder 2009. Scoped enums are generally characterized as follows: • Enumerators are in the scope of their enum. • Enumerators and enums do not implicitly convert to int (as do "plain" enumerators and enums). • Enums and their enumerators can have a defined underlying type.
Type Specifier decltype (C++0x) (see page 499)	The C++0x standard includes the **decltype** keyword and operator, which represents the type of an expression. This feature is one of the C++0x features added to C++Builder 2009.
Unicode Character Types and Literals (C++0x) (see page 500)	C++Builder 2009 implements new character types and character literals for Unicode. These types are among the C++0x features added to C++Builder 2009.

3.1.3.1.19.1 alignof Operator (C++0x)

The C++0x standard includes the **alignof** keyword and operator, which tells you the alignment of a type.

To get the alignment of a type, use the following syntax:

```
alignof(type);
```

The result is an integer constant of type `std::size_t`. The value indicates the boundaries on which elements of that type are aligned in memory. For instance, an alignment of 2 means that the type must begin on even memory addresses. A typical value for `alignof (double)` might be 8.

Applying **alignof** to a reference type yields the alignment of the referenced type. If you apply **alignof** to an array type, you get the alignment of its element's type.

Working Draft - Standard for Programming Language C++ (Sec. 5.3.6)

3.1.3.1.19.2 Type Trait Functions (C++0x)

This section contains Type Trait Functions help topics.

Topics

Name	Description
Type Trait Functions Overview (C++0x) (see page 472)	C++Builder 2009 supports a library of type trait functions designed to support compile time metaprogramming techniques. These type trait functions are intrinsic type functions that are defined in a manner similar to **typeid**, **sizeof**, and **decltype**. The type trait functions accept a type at compile time and deliver a compile time constant expression as a result, typically of type **bool**. Each type trait function is named after its respective type trait, prefixed with a double underscore (__), which marks a name reserved to the implementation. For example, the following is a type trait function that evaluates... more (see page 472)

__alignment_of (see page 473)	**Category** Type Trait Functions **Syntax:** `unsigned int __alignment_of( typename T )` This function is not necessary, as alignof (see page 531) is a proposed new keyword.
__array_extent (see page 473)	**Category** Type Trait Functions **Syntax** `unsigned int __array_extent( typename T, unsigned intI )` Returns: If T is not an array type, or if it has rank less than I, or if `I` is 0 and T has type “array of unknown bound of U”, then 0; otherwise, the size of the `I`'th dimension of T.
__array_rank (see page 473)	**Category** Type Trait Functions **Syntax** `unsigned int __array_rank( typename T )` Returns: If T names an array type, an integer representing the number of dimensions of T; otherwise, 0..
__has_nothrow_assign (see page 473)	**Category** Type Trait Functions **Syntax** `bool __has_nothrow_assign ( typename T )` Returns true if and only if compiler can prove T has a copy assignment operator that it cannot throw. True if __has_trivial_assign(T). Also true if copy assignment operator has an empty exception specification. **Ox interaction** false if copy assignment is defined as deleted.
__has_nothrow_copy_constructor (see page 474)	**Category** Type Trait Functions **Syntax** `bool __has_nothrow_copy_constructor ( typename T )` Returns true if and only if compiler can prove T has a copy constructor that cannot throw. **Error** if T is an incomplete type. True if `__has_trivial_copy_constructor(T)`. **Ox interaction** false if copy constructor is defined as deleted.
__has_nothrow_default_constructor (see page 474)	**Category** Type Trait Functions **Syntax** `bool __has_nothrow_default_constructor (typename T )` Returns true if and only if T can prove T has a default constructor it cannot throw. **Error** if T is an incomplete type. True if `__has_trivial_default_constructor(T)`. True if default constructor has an empty exception specification. False (but well-formed) if a class type does not have a default constructor. False if T is a reference type. **Ox interaction** false if the default constructor is defined as deleted.

__has_trivial_assign (see page 475)	**Category** Type Trait Functions **Syntax** `bool __has_trivial_assign (typename T )` Returns true if and only if T has a trivial copy assignment operator. **Error** if T is an incomplete type. The definition from Section 20.4.4.3 of the Working Draft notes says a type T has a trivial copy assignment operator if T is neither const nor a reference type and T is one of: • a scalar type (or array thereof) • a class type with a trivial copy assignment operator According to Section 21.8 p11 of the Working Draft, a copy assignment operator for class X is trivial if: • It is... more (see page 475)
__has_trivial_copy_constructor (see page 475)	**Category** Type Trait Functions **Syntax** `bool __has_trivial_copy_constructor ( typename T )` Returns true if and only if T has a trivial default constructor. **Error** if T is an incomplete type. False (but well-formed) if a class type does not have a default constructor The definition (from Section 20.4.4.3 of the Working Draft) notes has a type T has a trivial copy constructor if it is in the list:: • a scalartype (or array thereof) • a reference type (or array thereof) • an array of class type with trivial destructor • a class type with a trivial copy constructor (12.8) According to Section 12.8... more (see page 475)
__has_trivial_default_constructor (see page 476)	**Category** Type Trait Functions **Syntax** `bool __has_trivial_default_constructor (typename T )` Returns true if and only if T has a trivial default constructor. **Error**if T is an incomplete type. False (but well-formed) if a class type does not have a default constructor. According to the definition from Section 20.4.4.3 of the Working Draft notes, a type T has a trivial copy assignment operator if: • a scalar type (or array thereof) • an array of class type with a trivial default constructor • a class type with a trivial default constructorr Especially note false for reference types. According to Section 21.1 p5 of... more (see page 476)

__has_trivial_destructor (see page 477)	**Category** Type Trait Functions **Syntax** `bool __has_trivial_destructor (typename T )` Returns true if and only if T has a trivial destructor. **Error**if T is an incomplete type. Note: Definition from 20.4.4.3 notes has a type T has a trivial destructor if T is one of: • a scalartype (or array thereof) • a scalartype (or array thereof) • an array of class type with a trivial destructor • an array of class type with a trivial destructor • a class type with a trivial destructor According to Section 12.4, p 3 of the Working Draft, a destructor for class X is trivial if: • it... more (see page 477)
__has_virtual_destructor (see page 478)	**Category** Type Trait Functions **Syntax** `bool __has_virtual_destructor (typename T )` Returns true if and only if T is a class type and the destructor is declared virtual. **Error** if T is an incomplete type. Derived classes have a virtual destructor if the a base class destructor is declared virtual, even if not explicitly declared as virtual in the derived class.
__is_abstract (see page 478)	**Category** Type Trait Functions **Syntax** `bool __is_abstract( typename T )` Returns true if and only if T is an abstract class type. **Error** if T is an incomplete type. **Note:** An abstract class is one that contains or inherits (without overriding) at least one pure virtual function, according to Section 10.4 of the Working Draft.
__is_arithmetic (see page 478)	**Category** Type Trait Functions **Syntax** `bool __is_arithmetic ( typename T )` Returns __is_integral(T) || __is_floating_point(T).
__is_array (see page 479)	**Category** Type Trait Functions **Syntax** `bool __is_array( typename T )` Returns true if and only if T is an array type. **Note:** False for decayed pointer-to-array and reference to array; true for array-of-unknown bounds.
__is_base_of (see page 479)	**Category** Type Trait Functions **Syntax** `bool __is_base_of (typename Base, typename Derived)` Returns true if and only if Base is a base class of Derived. **Error** if Derived is an incomplete type and Base is a class-type.. Note: False (but well formed) if either Base or Derived is a union or non-class type, even if the other is an incomplete type. True if any class in the DAG of base classes for Derived is Base. This includes private, protected, ambiguous or virtual bases so simply return true the first time the search finds a match.

__is_class (see page 479)	**Category** Type Trait Functions **Syntax** `bool __is_class(typename T)` Returns true if and only if T is a class type, and NOT a union type. Returns true for classes declared with the class key class or struct. Returns false for reference/pointer to class type. Returns true for specialization of a class template. Ill-formed if called with the name of a template, without specifying the template parameters. A template is not a type; it is a type generator.
__is_complete_type (typename T) (see page 480)	**Category** Type Trait Functions **Syntax** `bool __is_complete_type(T)` Returns True if and only if T is a complete type at the point of the function call. This is a support function to help users track ill-formed code, not a distinct type trait required by the standard. This function is typically used in `static_assert` statements, because most other uses risk violating the ODR. Note that void and arrays of unknown bound are always incomplete types.
__is_compound (see page 480)	**Category** Type Trait Functions **Syntax** `bool __is_compound( typename T )` Returns true if and only if T is a compound type.. A compound type is essentially one item from the following list: • array • function • pointer • pointer-to-member • reference • class • union • enumeration Compound types are defined in Section 3.92 of the Working Draft.
__is_const (see page 481)	**Category** Type Trait Functions **Syntax** `bool __is_const(typename T)` Returns true if and only if T is a const-qualified type. Note: References are never cv-qualified. For pointers, refers to the pointer type itself, and NOT the pointed-to type. Returns true if T is both const and volatile qualified.
__is_convertible (see page 481)	**Category** Type Trait Functions **Syntax** `bool __is_convertible ( typename From, typename To )` Returns true if and only if **From** is implicitly convertible to **To**. Error if either From or To is an incomplete type. Note: Exact test described in Working Draft Section 20.4.4.3 is true if the following code is well formed:

__is_empty (see page 481)	**Category** Type Trait Functions **Syntax** `bool __is_empty( typename T )` Returns true if and only if T is an 'empty' type. **Error** if T is an incomplete type Definition of `__is_empty` is given in the table in Section 20.4.4.3 of the Working Draft. A type T is *empty* if T: • is a class type but not a union type. • has no non-static data members other than bit-fields of length 0 • has no virtual member functions • has no virtual base classes • has no base class which is not *empty*.
__is_enum (see page 482)	**Category** Type Trait Functions **Usage:** `bool _is_enum ( typename T )` Returns true if and only if T is an enum type. Returns true for the C++0x strongly typed enums as well. Returns false for reference/pointer to enum type.
__is_floating_point (see page 482)	**Category** Type Trait Functions **Syntax** `bool __is_floating_point(typename T)` Returns true if and only if T is a (potentially cv-qualified) floating point type. The standard set of floating point types is: • floating • double • long double Floating point types are defined in Section 3.9.1 p 7 of the Working Draft.
__is_function (see page 483)	**Category** Type Trait Functions **Syntax** `bool __is_function( typename T )` Returns true if and only if T is a function type. Returns false for reference/pointer to function type. Returns true for specialization of a function template. Ill-formed if called with the name of a template, without specifying the template parameters. A template is not a type; it is a type generator.
__is_fundamental (see page 483)	**Category** Type Trait Functions **Syntax** `bool __is_fundamental( typename T )` Returns true if and only if T is a fundamental type. Fundamental types are defined in Section 3.9.1 of the Working Draft. Definition is essentially `__is_arithmetic(T) || __is_void(T)` Alternative is a compound type, such as pointer, reference, enum, class or array.

__is_integral (see page 484)	**Category** Type Trait Functions **Syntax** `bool __is_integral(typename T)` Returns True if and only if T is an (potentially cv-qualified) integral type. Integral types are defined in the Working Standard, Section 3.9.1 page 7. The standard set of integral types is: bool, char, signed char, unsigned char, char16_t, char32_t, wchar_t, [unsigned]short, [unsigned] int, [unsigned] long, and [unsigned] long.
__is_lvalue_expr (see page 484)	**Category** Type Trait Functions **Syntax** `bool __is_lvalue_expr( typename T )` Returns true if and only if T is an lvalue expression.
__is_lvalue_reference (see page 484)	**Category** Type Trait Functions **Syntax** `bool __is_lvalue_reference( typename T )` Returns true if and only if T is an lvalue reference type. Can be a reference to an object or function type.
__is_member_function_pointer (see page 485)	**Category** Type Trait Functions **Syntax** `bool __is_member_function_pointer( typename T )` Returns true if and only if T is a pointer-to-member-function type . Returns false for a pointer-to-data member. Returns false for a regular object pointer.
__is_member_object_pointer (see page 485)	**Category** Type Trait Functions **Syntax** `bool __is_member_object_pointer( typename T )` Returns true if and only if T is a pointer-to-data-member type. Returns false for pointer-to-member-function. Returns false for a regular object pointer.
__is_member_pointer (see page 485)	**Category** Type Trait Functions **Syntax** `bool __is_member_pointer( typename T )` Returns: `__is_member_object_pointer(T) || __is_member_function_pointer(T)`.
__is_object (see page 485)	**Category** Type Trait Functions **Syntax** `bool __is_object( typename T)` Returns true if and only if T is an object type. Defined in Section 3.9 p8 of the Working Draft, essentially: `!__is_reference(T) && !__is_function(T) && !__is_void(T)`.
__is_pod (see page 486)	**Category** Type Trait Functions **Syntax** `bool __is_pod( typename T )` Returns true if and only if T is a POD (plain ol' data) type. **Error** if T is an incomplete type. POD types are defined in Section 3.9 p10 of the Working Draft. POD classes are defined in Section 9 p9 of the Working Draft. Effectively __is_trivial_type(T) && is standard_layout(T)
__is_pointer (see page 486)	**Category** Type Trait Functions **Syntax** `bool __is_pointer( typename T )` Returns true if and only if T is a pointer type. Can be an object pointer or a function pointer. False for pointer-to-member.

__is_polymorphic (see page 487)	**Category** Type Trait Functions **Syntax** `bool __is_polymorphic( typename T )` Returns true if and only if T is a poiymorphic class type. **Error** if T is an incomplete type. Polymorphic classes are defined in Section 10.3 of the Working Draft. "A class that declares or inherits a virtual function is called a polymorphic class."
__is_reference (see page 487)	**Category** Type Trait Functions **Syntax** `bool __is_reference( typename T )` Returns: `__is_lvalue_reference(T) || __is_rvalue_reference(T)`.
__is_rvalue_expr (see page 487)	**Category** Type Trait Functions **Syntax** `bool __is_rvalue_expr( typename T )` Returns true if and only if T is an rvalue expression.
__is_rvalue_reference (see page 488)	**Category** Type Trait Functions **Usage:** `bool __is_rvalue_reference( typename T )` Returns true if and only if T is an rvalue reference type. Can be a reference to an object or function type, even though function type rvalues make little sense beyond metaprogramming in the type system.
__is_same (see page 488)	**Category** Type Trait Functions **Syntax** `bool __is_same( typename T, typename U )` Returns true if and only if T and U are the same type, with identical CV qualifiers. Names of types when calling `__is_same` may be different aliases for the same type, if called with typedefs or template type parameters. **Ox** interaction: template aliases will allow another way to alias the same type name.

__is_scalar (see page 488)	**Category**
	Type Trait Functions
	Syntax
	`bool __is_scalar( typename T )`
	Returns true if and only if T is a scalar type.
	Scalar type is defined in Section 3.9 p10 of the Working Draft, essentially:
	`__is_arithmetic( T ) || __is_enumeration(T) || __is_pointer(T) || __is_member_pointer(T)`
	Scalar types have a built in meaning for operator < as well as operator ==. Therefore, `__closure` is not a scalar type.

__is_signed (see page 489)	**Category** Type Trait Functions **Syntax** `_bool __is_signed( typename T )` Returns true if and only if `__is_arithmetic(T)` and T recognizes values less than zero.

__is_standard_layout (see page 489)	**Category** Type Trait Functions **Syntax** `bool __is_standard_layout(typename T)` Returns true if and only if T is a standard layout type. **Error** if T is an incomplete type. Standard layout classes are defined in Section 9, p 6 of the Working Draft. A standard layout type is: • a scalar type • an array of standard layout types • a standard layout class type: A standard layout class is a class that has: • no non-static data members other than standard layout types • same access control for all non-static data members (such as all public or private) • no base classes other than standard layout classes... more (see page 489)
__is_trivial (see page 490)	**Category** Type Trait Functions **Syntax** `bool __is_trivial( typename T )` Returns true if and only if T is a trivial type. **Error** if T is an incomplete type. Trivial types are defined in Section 3.9 p10 of the Working Draft. Trivial classes are defined in Section 9 p5 of the Working Draft. Returns true if T is both const and volatile qualified. A type is trivial if it is: • a scalar type • an array of trivial types • a class/union type where all 4 special members are trivial: • default constructor • copy constructor • copy assignment operator • destructor Consult this online help for... more (see page 490)
__is_union (see page 491)	**Category** Type Trait Functions **Syntax** `bool __is_union( typename T )` Returns true if and only if T is a union type. Note: unions are class types declared with the class-key union. Returns false for reference/pointer to union type.
__is_unsigned (typename T) (see page 491)	**Category** Type Trait Functions **Syntax** `bool __is_unsigned` Returns true if `_is_arithmetic(T)` and T does not recognize values less than zero

__is_void (see page 491)	**Category** Type Trait Functions **Syntax** `bool __is_void( typename T )` Returns True if T is (potentially cv-qualified) void. Returns False otherwise, including for pointer or reference to void.
__is_volatile (see page 491)	**Category** Type Trait Functions **Syntax** `bool __is_volatile( typename T )` Returns true if and only if T is a volatile-qualified type.. Note: References are never cv-qualified. For pointers, refers to the pointer type itself, and NOT the pointed-to type. Returns true if T is both const and volatile qualified.

3.1.3.1.19.2.1 Type Trait Functions Overview (C++0x)

C++Builder 2009 supports a library of type trait functions designed to support compile time metaprogramming techniques.

These type trait functions are intrinsic type functions that are defined in a manner similar to **typeid**, **sizeof**, and **decltype**. The type trait functions accept a type at compile time and deliver a compile time constant expression as a result, typically of type **bool**.

Each type trait function is named after its respective type trait, prefixed with a double underscore (__), which marks a name reserved to the implementation.

For example, the following is a type trait function that evaluates True if T is a union type, or False otherwise:

```
bool __is_union(typename T)
```

The **typename** keyword here indicates a function that takes a type rather than a value as an argument, for illustration purposes only.

Differences Between Type Trait Functions and Other Intrinsic Functions

Type trait functions accept only named types, not arbitrary expressions (which would be accepted by **typeid**, **sizeof**, and **decltype**). You can specify multiple arguments with a type trait function, but a comma-separated list is interpreted as an application of the comma operator by **typeid**, **sizeof**, and **decltype**.

Similarly, any attempt to reference the type of a bit field (such as through **decltype**) produces the underlying storage type for the bit field, and that is what is tested in the type trait functions.

Incomplete Types and Type Trait Functions

Many of the type trait functions do work with incomplete types. For example, after a class has been forward declared, the type can be identified as a class, not a union, enum or fundamental type. The class can have references and pointers, and so forth. Therefore, most type trait functions accept two special incomplete types: void and array-of-unknown-bound (of complete types). For these two incomplete types, most type trait functions return False.

However, a few type functions require complete types. For example, a class declaration is not sufficient to know about bases or triviality.

For convenience, the following type trait function is implemented in C++Builder:

```
__is_complete_type(T)
```

This type trait function is unique in that it might return different results at compile time depending on its location in the translation unit. This phenomenon makes this type trait function ripe for ODR violations when used carelessly.

A table of type trait functions that require that the type be a complete type, an array of unknown bound, or (possibly cv-qualified) `void` is given in **Table 43**: “Type Property Predicates” in Section 20 of the Working Draft.

3.1.3.1.19.2.2 __alignment_of

Category

Type Trait Functions

Syntax:

```
unsigned int __alignment_of( typename T )
```

This function is not necessary, as alignof (see page 531) is a proposed new keyword.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 463)

3.1.3.1.19.2.3 __array_extent

Category

Type Trait Functions

Syntax

```
unsigned int __array_extent( typename T, unsigned intI )
```

Returns: If T is not an array type, or if it has rank less than I, or if `I` is 0 and `T` has type “array of unknown bound of U”, then 0; otherwise, the size of the `I`’th dimension of `T`.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.4 __array_rank

Category

Type Trait Functions

Syntax

```
unsigned int __array_rank( typename T )
```

Returns: If T names an array type, an integer representing the number of dimensions of T; otherwise, 0..

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.5 __has_nothrow_assign

Category

Type Trait Functions

Syntax

```
bool __has_nothrow_assign ( typename T )
```

Returns true if and only if compiler can prove T has a copy assignment operator that it cannot throw.

True if __has_trivial_assign(T).

Also true if copy assignment operator has an empty exception specification.

Ox interaction false if copy assignment is defined as deleted.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.6 __has_nothrow_copy_constructor

Category

Type Trait Functions

Syntax

```
bool __has_nothrow_copy_constructor ( typename T )
```

Returns true if and only if compiler can prove T has a copy constructor that cannot throw.

Error if T is an incomplete type.

True if `__has_trivial_copy_constructor(T)`.

Ox interaction false if copy constructor is defined as deleted.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.7 __has_nothrow_default_constructor

Category

Type Trait Functions

Syntax

```
bool __has_nothrow_default_constructor (typename T )
```

Returns true if and only if T can prove T has a default constructor it cannot throw.

Error if T is an incomplete type.

True if `__has_trivial_default_constructor(T)`.

True if default constructor has an empty exception specification.

False (but well-formed) if a class type does not have a default constructor.

False if T is a reference type.

Ox interaction false if the default constructor is defined as deleted.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.8 __has_trivial_assign

Category

Type Trait Functions

Syntax

```
bool __has_trivial_assign (typename T )
```

Returns true if and only if T has a trivial copy assignment operator.

Error if T is an incomplete type.

The definition from Section 20.4.4.3 of the Working Draft notes says a type T has a trivial copy assignment operator if T is neither const nor a reference type and T is one of:

- a scalar type (or array thereof)
- a class type with a trivial copy assignment operator

According to Section 21.8 p11 of the Working Draft, a copy assignment operator for class X is trivial if:

- It is not user provided
- class X has no virtual functions
- class X has no virtual base classes
- each direct base class of X has a trivial copy assignment operator.
- for all the non-static data members of X that are of class type (or array thereof), each such class type has a trivial copy assignment operator;

A copy assignment operator is not user provided if it is implicitly declared, or defined inline as `= default;`.

Ox interaction false if the copy assign operator is defined as deleted.

Ox interaction false if the copy assign operator is defined as deleted.

Ox interaction false if the default constructor is defined as deleted.

Ox interaction with default function definitions.

Type Trait Functions Overview (see page 472)

Working Draft - Standard for Programming Language C++ - http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2008/n2588.pdf

3.1.3.1.19.2.9 __has_trivial_copy_constructor

Category

Type Trait Functions

Syntax

```
bool __has_trivial_copy_constructor ( typename T )
```

Returns true if and only if T has a trivial default constructor.

Error if T is an incomplete type.

False (but well-formed) if a class type does not have a default constructor

The definition (from Section 20.4.4.3 of the Working Draft) notes has a type T has a trivial copy constructor if it is in the list::

- a scalartype (or array thereof)
- a reference type (or array thereof)
- an array of class type with trivial destructor
- a class type with a trivial copy constructor (12.8)

According to Section 12.8 p6 of the Working Draft:

A copy constructor for class X is trivial if:

- It is not user provided (see Section 8.4)
- class X has no virtual functions
- class X has no virtual base classes
- each direct base class of X has a trivial copy constructor.
- for all the non-static data members of X that are of class type (or array thereof), each such class type has a trivial copy constructor;.

A copy constructor is not user provided if it is implicitly declared, or defined inline as `= default;`

Ox interaction false if the default constructor is defined as deleted.

Ox interactionwith default function definitions.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

Working Draft - Standard for Programming Language C++: http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2008/n2588.pdf

3.1.3.1.19.2.10 __has_trivial_default_constructor

Category

Type Trait Functions

Syntax

```
bool __has_trivial_default_constructor (typename T )
```

Returns true if and only if T has a trivial default constructor.

Errorif T is an incomplete type.

False (but well-formed) if a class type does not have a default constructor.

According to the definition from Section 20.4.4.3 of the Working Draft notes, a type T has a trivial copy assignment operator if:

- a scalar type (or array thereof)
- an array of class type with a trivial default constructor
- a class type with a trivial default constructorr

Especially note false for reference types.

According to Section 21.1 p5 of the Working Draft, a default constructor is trivial if:

- It is not user provided

- Its class has no virtual functions
- Its class has no virtual base classes
- Each direct base class of X has a trivial copy assignment operator.
- All the direct base classes of its class have trivial default constructors.
- For all the non-static data members of its class that are of class type (or array thereof), each such class has a trivial default constructor.

A default consructor is not user provided if it is implicitly declared, or defined inline as `= default;`.

Ox interaction if the copy assign operator is defined as deleted.

Ox interaction false if the default constructor is defined as deleted.

Ox interaction with default function definitions.

Type Trait Functions Overview (see page 472)

Working Draft - Standard for Programming Language C++ - http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2008/n2588.pdf

3.1.3.1.19.2.11 __has_trivial_destructor

Category

Type Trait Functions

Syntax

```
bool __has_trivial_destructor (typename T )
```

Returns true if and only if T has a trivial destructor.

Errorif T is an incomplete type.

Note: Definition from 20.4.4.3 notes has a type T has a trivial destructor if T is one of:

- a scalartype (or array thereof)
- a scalartype (or array thereof)
- an array of class type with a trivial destructor
- an array of class type with a trivial destructor
- a class type with a trivial destructor

According to Section 12.4, p 3 of the Working Draft, a destructor for class X is trivial if:

- it is not user-provided
- class X has no virtual functions
- class X has no virtual base classes
- all of the direct base classes of its class have trivial destructors
- for all of the non-static data members of its class that are of class type (or array thereof), each such class has a trivial destructor.

A destructor is not user provided if it is implicitly declared, or defined inline as = default;

Ox interaction false if the destructor is defined as deleted.

Ox interaction with default function definitions.

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.12 __has_virtual_destructor

Category

Type Trait Functions

Syntax

```
bool __has_virtual_destructor (typename T )
```

Returns true if and only if T is a class type and the destructor is declared virtual.

Error if T is an incomplete type.

Derived classes have a virtual destructor if the a base class destructor is declared virtual, even if not explicitly declared as virtual in the derived class.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.13 __is_abstract

Category

Type Trait Functions

Syntax

```
bool __is_abstract( typename T )
```

Returns true if and only if T is an abstract class type.

Error if T is an incomplete type.

Note: An abstract class is one that contains or inherits (without overriding) at least one pure virtual function, according to Section 10.4 of the Working Draft.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

Working Draft — Standard for Programming Language C++ - http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2008/n2588.pdf

3.1.3.1.19.2.14 __is_arithmetic

Category

Type Trait Functions

Syntax

```
bool __is_arithmetic ( typename T )
```

Returns __is_integral(T) || __is_floating_point(T).

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.15 __is_array

Category

Type Trait Functions

Syntax

```
bool __is_array( typename T )
```

Returns true if and only if T is an array type.

Note: False for decayed pointer-to-array and reference to array; true for array-of-unknown bounds.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.16 __is_base_of

Category

Type Trait Functions

Syntax

```
bool __is_base_of (typename Base, typename Derived)
```

Returns true if and only if Base is a base class of Derived.

Error if Derived is an incomplete type and Base is a class-type..

Note: False (but well formed) if either Base or Derived is a union or non-class type, even if the other is an incomplete type.

True if any class in the DAG of base classes for Derived is Base. This includes private, protected, ambiguous or virtual bases so simply return true the first time the search finds a match.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.17 __is_class

Category

Type Trait Functions

Syntax

```
bool __is_class(typename T)
```

Returns true if and only if T is a class type, and NOT a union type.

Returns true for classes declared with the class key class or struct.

Returns false for reference/pointer to class type.

Returns true for specialization of a class template.

Ill-formed if called with the name of a template, without specifying the template parameters. A template is not a type; it is a type generator.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.18 __is_complete_type (typename T)

Category

Type Trait Functions

Syntax

```
bool __is_complete_type(T)
```

Returns True if and only if T is a complete type at the point of the function call.

This is a support function to help users track ill-formed code, not a distinct type trait required by the standard. This function is typically used in `static_assert` statements, because most other uses risk violating the ODR. Note that void and arrays of unknown bound are always incomplete types.

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.19 __is_compound

Category

Type Trait Functions

Syntax

```
bool __is_compound( typename T )
```

Returns true if and only if T is a compound type..

A compound type is essentially one item from the following list:

- array
- function
- pointer
- pointer-to-member
- reference
- class
- union
- enumeration

Compound types are defined in Section 3.92 of the Working Draft.

3.1.3.1.19.2.20 __is_const

Category

Type Trait Functions

Syntax

```
bool __is_const(typename T)
```

Returns true if and only if T is a const-qualified type.

Note: References are never cv-qualified.

For pointers, refers to the pointer type itself, and NOT the pointed-to type.

Returns true if T is both const and volatile qualified.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.21 __is_convertible

Category

Type Trait Functions

Syntax

```
bool __is_convertible ( typename From, typename To )
```

Returns true if and only if **From** is implicitly convertible to **To**.

Error if either From or To is an incomplete type.

Note: Exact test described in Working Draft Section 20.4.4.3 is true if the following code is well formed:

```
template <class T>
typename add_rvalue_reference<T>::type create();

To test() { return create<From>(); |
```

Type Trait Functions Overview (see page 472)

Working Draft - Standard for Programming Language C++ - http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2008/n2588.pdf

3.1.3.1.19.2.22 __is_empty

Category

Type Trait Functions

Syntax

```
bool __is_empty( typename T )
```

Returns true if and only if T is an 'empty' type.

Error if T is an incomplete type

Definition of `__is_empty` is given in the table in Section 20.4.4.3 of the Working Draft.

A type T is *empty* if T:

- is a class type but not a union type.
- has no non-static data members other than bit-fields of length 0
- has no virtual member functions
- has no virtual base classes
- has no base class which is not *empty*.

Type Trait Functions Overview (see page 472)

Working Draft — Standard for Programming Language C++ - http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2008/n2588.pdf

3.1.3.1.19.2.23 __is_enum

Category

Type Trait Functions

Usage: `bool _is_enum ( typename T )`

Returns true if and only if T is an enum type.

Returns true for the C++0x strongly typed enums as well.

Returns false for reference/pointer to enum type.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.24 __is_floating_point

Category

Type Trait Functions

Syntax

```
bool __is_floating_point(typename T)
```

Returns true if and only if T is a (potentially cv-qualified) floating point type.

The standard set of floating point types is:

- floating
- double

- long double

Floating point types are defined in Section 3.9.1 p 7 of the Working Draft.

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

Working Draft — Standard for Programming Language C++ - http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2008/n2588.pdf

3.1.3.1.19.2.25 __is_function

Category

Type Trait Functions

Syntax

```
bool __is_function( typename T )
```

Returns true if and only if T is a function type.

Returns false for reference/pointer to function type.

Returns true for specialization of a function template.

Ill-formed if called with the name of a template, without specifying the template parameters. A template is not a type; it is a type generator.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions (C++0x) (see page 472)

3.1.3.1.19.2.26 __is_fundamental

Category

Type Trait Functions

Syntax

```
bool __is_fundamental( typename T )
```

Returns true if and only if T is a fundamental type.

Fundamental types are defined in Section 3.9.1 of the Working Draft.

Definition is essentially `__is_arithmetic(T) || __is_void(T)`

Alternative is a compound type, such as pointer, reference, enum, class or array.

3.1.3.1.19.2.27 __is_integral

Category

Type Trait Functions

Syntax

```
bool __is_integral(typename T)
```

Returns True if and only if T is an (potentially cv-qualified) integral type.

Integral types are defined in the Working Standard, Section 3.9.1 page 7.

The standard set of integral types is: bool, char, signed char, unsigned char, char16_t, char32_t, wchar_t, [unsigned]short, [unsigned] int, [unsigned] long, and [unsigned] long.

3.1.3.1.19.2.28 __is_lvalue_expr

Category

Type Trait Functions

Syntax

```
bool __is_lvalue_expr( typename T )
```

Returns true if and only if T is an lvalue expression.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.29 __is_lvalue_reference

Category

Type Trait Functions

Syntax

```
bool __is_lvalue_reference( typename T )
```

Returns true if and only if T is an lvalue reference type.

Can be a reference to an object or function type.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.30 __is_member_function_pointer

Category

Type Trait Functions

Syntax

```
bool __is_member_function_pointer( typename T )
```

Returns true if and only if T is a pointer-to-member-function type .

Returns false for a pointer-to-data member.

Returns false for a regular object pointer.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.31 __is_member_object_pointer

Category

Type Trait Functions

Syntax

```
bool __is_member_object_pointer( typename T )
```

Returns true if and only if T is a pointer-to-data-member type.

Returns false for pointer-to-member-function.

Returns false for a regular object pointer.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.32 __is_member_pointer

Category

Type Trait Functions

Syntax

```
bool __is_member_pointer( typename T )
```

Returns: `__is_member_object_pointer(T) || __is_member_function_pointer(T)`.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.33 __is_object

Category

Type Trait Functions

Syntax

```
bool __is_object( typename T)
```

Returns true if and only if T is an object type.

Defined in Section 3.9 p8 of the Working Draft, essentially:

`!__is_reference(T) && !__is_function(T) && !__is_void(T)`.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

Working Draft — Standard for Programming Language C++ - http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2008/n2588.pdf

3.1.3.1.19.2.34 __is_pod

Category

Type Trait Functions

Syntax

```
bool __is_pod( typename T )
```

Returns true if and only if T is a POD (plain ol' data) type.

Error if T is an incomplete type.

POD types are defined in Section 3.9 p10 of the Working Draft.

POD classes are defined in Section 9 p9 of the Working Draft.

Effectively __is_trivial_type(T) && is standard_layout(T)

3.1.3.1.19.2.35 __is_pointer

Category

Type Trait Functions

Syntax

```
bool __is_pointer( typename T )
```

Returns true if and only if T is a pointer type.

Can be an object pointer or a function pointer.

False for pointer-to-member.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.36 __is_polymorphic

Category

Type Trait Functions

Syntax

```
bool __is_polymorphic( typename T )
```

Returns true if and only if T is a poiymorphic class type.

Error if T is an incomplete type.

Polymorphic classes are defined in Section 10.3 of the Working Draft.

"A class that declares or inherits a virtual function is called a polymorphic class."

3.1.3.1.19.2.37 __is_reference

Category

Type Trait Functions

Syntax

```
bool __is_reference( typename T )
```

Returns: `__is_lvalue_reference(T) || __is_rvalue_reference(T)`.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.38 __is_rvalue_expr

Category

Type Trait Functions

Syntax

```
bool __is_rvalue_expr( typename T )
```

Returns true if and only if T is an rvalue expression.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.39 __is_rvalue_reference

Category

Type Trait Functions

Usage: `bool __is_rvalue_reference( typename T )`

Returns true if and only if T is an rvalue reference type.

Can be a reference to an object or function type, even though function type rvalues make little sense beyond metaprogramming in the type system.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.40 __is_same

Category

Type Trait Functions

Syntax

```
bool __is_same( typename T, typename U )
```

Returns true if and only if T and U are the same type, with identical CV qualifiers.

Names of types when calling `__is_same` may be different aliases for the same type, if called with typedefs or template type parameters.

Ox interaction: template aliases will allow another way to alias the same type name.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.41 __is_scalar

Category

Type Trait Functions

Syntax

```
bool __is_scalar( typename T )
```

Returns true if and only if T is a scalar type.

Scalar type is defined in Section 3.9 p10 of the Working Draft, essentially:

```
__is_arithmetic( T ) || __is_enumeration(T) ||
__is_pointer(T) || __is_member_pointer(T)
```

Scalar types have a built in meaning for operator < as well as operator ==. Therefore, `__closure` is not a scalar type.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

Working Draft — Standard for Programming Language C++ - http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2008/n2588.pdf

3.1.3.1.19.2.42 __is_signed

Category

Type Trait Functions

Syntax

```
_bool __is_signed( typename T )
```

Returns true if and only if `__is_arithmetic(T)` and T recognizes values less than zero.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.43 __is_standard_layout

Category

Type Trait Functions

Syntax

```
bool __is_standard_layout(typename T)
```

Returns true if and only if T is a standard layout type.

Error if T is an incomplete type.

Standard layout classes are defined in Section 9, p 6 of the Working Draft.

A standard layout type is:

- a scalar type
- an array of standard layout types
- a standard layout class type:

A standard layout class is a class that has:

- no non-static data members other than standard layout types
- same access control for all non-static data members (such as all public or private)
- no base classes other than standard layout classes
- no virtual functions and no virtual base classes
- no more than one class in the DAG of inheritance tree has any non-static data
- no base class of same type as the first (if any) non-static data member

Standard layout types trigger several special clauses in the standard, which may affect code generation and optimizations, or simply whether certain constructs are undefined. In particular, standard layout classes require the empty base optimization.

Note that standard layout types are a generalization of PODs in the 2003 standard, if the POD/standard layout refinement has

not happened when this type function is initially implanted.

Type Trait Functions Overview (see page 472)

Working Draft — Standard for Programming Language C++ - http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2008/n2588.pdf

3.1.3.1.19.2.44 __is_trivial

Category

Type Trait Functions

Syntax

```
bool __is_trivial( typename T )
```

Returns true if and only if T is a trivial type.

Error if T is an incomplete type.

Trivial types are defined in Section 3.9 p10 of the Working Draft.

Trivial classes are defined in Section 9 p5 of the Working Draft.

Returns true if T is both const and volatile qualified.

A type is trivial if it is:

- a scalar type
- an array of trivial types
- a class/union type where all 4 special members are trivial:
- default constructor
- copy constructor
- copy assignment operator
- destructor

Consult this online help for the definition of each `__has_trivial_*` traits.

Trivial types trigger several special clauses in the standard, which may affect code generation and optimizations, or simply whether certain constructs are undefined.

Note that trivial types are a generalization of PODs (plain old data objects) in the 2003 standard, if the POD/trivial refinement has not happened when this type function is initially implanted.

3.1.3.1.19.2.45 __is_union

Category

Type Trait Functions

Syntax

```
bool __is_union( typename T )
```

Returns true if and only if T is a union type.

Note: unions are class types declared with the class-key union.

Returns false for reference/pointer to union type.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.46 __is_unsigned (typename T)

Category

Type Trait Functions

Syntax

```
bool __is_unsigned
```

Returns true if `_is_arithmetic(T)` and T does not recognize values less than zero

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.47 __is_void

Category

Type Trait Functions

Syntax

```
bool __is_void( typename T )
```

Returns True if T is (potentially cv-qualified) void. Returns False otherwise, including for pointer or reference to void.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.2.48 __is_volatile

Category

Type Trait Functions

Syntax

```
bool __is_volatile( typename T )
```

Returns true if and only if T is a volatile-qualified type..

Note: References are never cv-qualified.

For pointers, refers to the pointer type itself, and NOT the pointed-to type.

Returns true if T is both const and volatile qualified.

C++0x Features (C++Builder 2009) (see page 462)

Type Trait Functions Overview (see page 472)

3.1.3.1.19.3 Attributes noreturn and final (C++0x)

The C++0x standard includes the addition of attributes that might be applied to the declaration of a class, a general function, a constructor, an array, and so forth. C++Builder 2009 implements two attributes: **noreturn** and **final**.

Attributes are set off in the code by double brackets, such as `[[noreturn]]`.

The noreturn Attribute

The **noreturn** attribute specifies that a function does not return. If a function marked **noreturn** is called and eventually executes a return statement, the program is considered ill-formed, but the compiler does not issue a message.

For example:

```
void f [[noreturn]] () {
   throw “error”;           // OK
}
void g [[noreturn]] (int i) {   // ill-formed if called with i<=0
   if (i > 0)
      throw “positive”;
}
```

The **noreturn** attribute is useful for a few library functions that cannot return, such as abort and exit. You can also define your own functions that never return by using the **noreturn** attribute.

For example:

```
void fatal(void) [[noreturn]];
void fatal(...)
{
...
        exit(1);
}
```

The noreturn keyword tells the C++ compiler to assume that fatal cannot return. The compiler can then optimize without regard to what would happen if fatal ever did return. Thus, using noreturn can make better code. More importantly, it helps avoid spurious warnings of uninitialized variables. You cannot assume that registers saved by the calling function are restored before calling the function with the noreturn attribute. It does not make sense for a noreturn function to have a return type other than void.

The final Attribute

The **final** attribute prevents a class or function from being further inherited. You can add the **final** attribute to a class definition or to a virtual member function declaration inside a class definition.

A class with the **final** attribute is not allowed to be a base class for another class. A virtual function with the **final** attribute is not overridden in a subclass. If the attribute is specified for a class definition, it is equivalent to being specified for each virtual

member function of that class, including inherited member functions.

If a virtual member function f in some class B is marked **final** and in a class D derived from B, a function D::f overrides B::f, the program is ill-formed (the compiler does not issue a message).

For example:

```
struct B {
   virtual void f [[ final ]] ();
};
struct D : B {
   void f();   // ill-formed
};
```

C++0x Features (C++Builder 2009) (see page 462)

noreturn (see page 557)

final (see page 550)

3.1.3.1.19.4 Explicit Conversion Operators (C++0x)

C++Builder 2009 includes support for explicit conversion operators, one of the features in the C++0x standard.

You can now apply the function specifier **explicit** in the definition of a user-defined conversion operator. Previously, explicit constructors (including copy constructors) were added to the language in order to prevent unintended conversions being implicitly called by the compiler. Now explicit conversion operators have been added to provide the same control over unintended conversion calls. .

Conversion functions declared as explicit work in the same contexts as explicit constructors (that is, direct-initialization, explicit type conversion). Explicit conversion operators produce compiler diagnostics in the same contexts (copy-initialization) as explicit constructors do.

For example:

```
class T { };

class X {

public:

explicit operator T() const;

};

void m() {

X x;

// with cast:

T tc = (T)x;// ok

// without cast:

T t = x;// error: E2034

// gets: Error E2034 x.cpp 13: Cannot convert 'X' to 'T' in function m()

}
```

Draft Working Paper

Summary of Working Group Papers

3.1.3.1.19.5 extern Templates (C++0x)

C++Builder 2009 includes the use of **extern** templates, which allow you to define templates that are not instantiated in a translation unit. Using **extern** templates thus reduces both compilation time and the size of the compiled module. This feature is part of the new C++0x standard.

Explicit Instantiation and Declaration

An **extern** template allows you to declare a template without instantiating it in the translation unit.

To illustrate, the following both creates and instantiates a template:

```
template <class T>
class MyClass {
   //various code
}

template class MyClass<int>;
...
MyClass<int> myClass;
```

The line `template class MyClass<int>` is an explicit template definition and causes the template to be instantiated explicitly in its code unit, resulting in generating code for the template in that unit. Similarly, the line `MyClass<int> myClass;` implicitly instantiates the template, also resulting in code generation in the unit. If either of these lines of code are in your unit, the template is instantiated there.

However, suppose you want to have a library in which all instantiations of this template occur, and you want to refer to these instantiations in an executable. To make an explicit template declaration that does not instantiate the template in your code unit, use the following:

```
extern template class MyClass<int>;
```

You can then reference the template, but the compiler does not generate code for it in that translation unit.

extern Template Usage

Here are the rules for using extern templates:

- A template instantiation must either follow an explicit template declaration in that translation unit or be in another translation unit. This is similar to the usual use of **extern**: the entity referenced must be defined somewhere.
- An explicit template definition must occur only once in a unit.
- An explicit template definition must follow an explicit template declaration if both are present in a translation unit.
- An explicit template declaration can only apply to names of objects, functions, and explicit template instantiations. It may not refer to a static function, but may apply to a static member function.
- The **extern** specifier may not be used in declaration of class members or parameters.
- An explicit template declaration only suppresses code generation if that template has not been instantiated with the same specialization. For instance:

```
template class MyClass<int>;
...
extern template class MyClass<int>;    // not allowed
extern template class MyClass<float>;  // OK
```

Working Draft - Standard for Programming Language C++ (Sec. 17.2)

3.1.3.1.19.6 Forward Declaration of Enums (C++0x)

C++Builder 2009 introduces forward declaration of enums. You can declare an enumeration without providing a list of enumerators. Such declarations would not be definitions and can be provided only for enumerations with fixed underlying types. An enumeration can then be re-declared, possibly providing the missing list of enumerators, but the re-declaration must match the previous declaration. This feature is one of the C++0x features added to C++Builder 2009.

```
enum E : short;           // OK: unscoped, underlying type is short
enum F:                   // illegal: enum-base is required
enum class G : short      // OK: scoped, underlying type is short
enum class H;             // OK: scoped, underlying type is int
enum E : short;           // OK: redeclaration of E
enum class G : short;     // OK: redeclaration of G
enum class H;             // OK: redeclaration of H
enum class H : int;       // OK: redeclaration of H
enum class E : short;     // illegal: previously declared as unscoped
enum G : short;           // illegal: previously declared as scoped
enum E;                   // illegal: enum-base is required
enum E : int              // illegal: different underlying type
enum class G;             // illegal: different underlying type
enum class H : short;     // illegal: different underlying type
enum class H {/* */}]     // OK:  this redeclaration is a definition
```

C++0x Features (C++Builder 2009) (see page 462)

Strongly Typed Enums (see page 498)

3.1.3.1.19.7 rvalue References (C++0x)

C++Builder 2009 includes the use of rvalue references, which allow creating a reference to temporaries. Also, rvalue references avoid unnecessary copying and make possible perfect forwarding functions. This feature is one of the C++0x features.

Description

Rvalue references are a compound type like standard C++ references, which are referred to as lvalue references. An lvalue reference is formed by appending the ampersand character (**&**) to a type:

```
SomeClass l;
SomeClass& lReference = l;    //lvalue rererence
```

The syntax of an rvalue reference is to add **&&** after a type:

```
SomeClass r;
SomeClass&& rReference = r;    //rvalue rererence
```

An rvalue reference behaves like an lvalue reference, except that you can bind an rvalue reference to a temporary -- an rvalue.

```
SomeClass a;
a = SomeClass();
SomeClass& lReference = a;          //OK-lvalue reference can bind to an lvalue such as "a"
SomeClass& lReference2 = SomeClass();   //error-lvalue reference can't bind to an rvalue
SomeClass&& rReference = SomeClass();   //OK for rvalue reference to bind to rvalue

// Both references can be used the same way
SomeOtherClass value1 = SomeFunc(lReference);
SomeOtherClass value2 = SomeFunc(rReference);
```

In the example above, `SomeClass()` is not bound to an identifiier, so it is an rvalue and can be bound to an rvalue reference -- but not an lvalue reference.

Eliminating Unnecessary Copying

In many cases, data is copied that simply needs to be moved, that is, the original data holder need not retain the data. An example is swapping data in two structures, so neither structure holds its previous data. It would be logically sufficient to simply switch the references to the data.

Rvalue rererences can be used to distinguish cases that require copying versus cases that merely require moving data. Since copying can be a lengthy operation, you want to avoid it if possible.

If a function wants to copy something that has been passed to it as an rvalue, then it can do a move rather than a copy, because it knows that the value is temporary. If a function is passed an lvalue, it may need to do a full copy if copy elision doesn't apply. You can distinguish these cases with the function signature.

Consider a class ExampleClass that has a clone function that makes a deep copy of class instances. You want to define a move function that moves an object's value. This function can be overloaded as follows:

```
// Parameter is lvalue
ExampleClass move(ExampleClass& l)
{
    return l.clone();   //returns a copy since we can't touch the original value

// Parameter is rvalue
ExampleClass move(ExampleClass&& r)
{
    return r;       //returns a reference since we don't care about the temporary's value
}
template class MyClass<int>;
...
extern template class MyClass<int>;    // not allowed
extern template class MyClass<float>;  // OK
```

We could then use the move function for both rvalues and lvalues:

```
ExampleClass a, b, c;
a = ExampleClass();
b = b.move(a);          //parameter is lvalue
c = c.move(ExampleClass()); //parameter is rvalue
```

Note that the move function for the rvalue parameter does very little, so it executes much more quickly than the move for an lvalue parameter.

You can use a similar technique for functions that need to make copies, such as copy constructors and assignment operators. Suppose we have a template class with a pointer to some other class, where clone is again a deep copy function:

```
template <class T>
class PointerClass
{
private:
    T* pointer;
public:
    // Regular constructor
    PointerClass(void);

    // Copy constructor for lvalues
    PointerClass(PointerClass& pcl) : pointer(pcl.pointer ? pcl.pointer.clone() : 0) {} //make
full copy
    // Copy constructor for rvalues
    PointerClass(PointerClass&& pcr) : pointer(pcr.pointer) {pcr.pointer = 0;}
```

The copy constructor that takes an rvalue:

- Does a move, not a copy. That is, it simply returns a reference to the data.

- Treats the rvalue argument **pcr** just like an lvalue in its code.
- Leaves the rvalue object in a defined state so that it can safely be deleted.

Non-Copyable but Movable Types

Types that are not copyable, such as ones that use unique_ptr, can be made movable. Although they cannot define assignment operators, they can implement move functions and swap functions, since these do not require copying when rvalue references are used. A sort function could be developed, since it only requires swapping, not copying.

For instance, consider this factory function that takes one argument:

```
template <class T, class U>
factory(const U& u)
{
    return new T(u);
}
```

The above definition of factory works in this case:

```
T* p = factory<T>(7);
```

However, a compiler error occurs when a T is used whose constructor's parameter is a non-const reference. You could fix this case by removing const from the definition:

```
template <class T, class U>
factory(U& u)
{
    return new T(u);
}
```

However, the previous example now fails:

```
T* p = factory<T>(7); // compiler error
T* u = new T(7);    //OK
```

This causes an error because the value 7 causes the template argument to be matched to int &, but this does not bind to the rvalue 7.

This could be remedied by defining a factory function for each case of const and non-const. This is problematic, because the number of functions needed increases exponentially with the number of arguments.

If you make the argument an rvalue reference, you can simplify the situation:

```
template <class T, class U.
factory(u&& u)
{
   return new T(forward<U>(u));
}
```

Now the argument **u** binds to both rvalues and lvalues. The `forward` function returns an rvalue or lvalue, exactly as it was passed. It can be defined in this way:

```
template <class U>
struct identity
{
    typedef U type;
};

template <class U>
U&& forward(typename identity<U>::type&& u)
{
    return u;
}
```

A Proposal to Add an Rvalue Reference to the C++ Language

A Brief Introduction to Rvalue References

3.1.3.1.19.8 Static Assertions (C++0x)

The **static_assert** keyword is used to test assertions at compile time. This is one of the C++0x features added to C++Builder 2009.

This keyword operates differently than the macro **assert**, which raises assertions at run time. The keyword **static_assert** also differs from the preprocessor directive **#error**, which operates during preprocessing and simply emits a message.

Syntax

A static assertion's declaration is:

```
static_assert (constant-expression, error-message);
```

The `constant-expression` must be one that can be statically evaluated as a boolean. If `constant-expression` is true, the statement does nothing. If false, the compiler generates an error with the text `error-message`. Because the assertion is tested at compile time, **static_assert** can do error checking in templates. For instance:

```
template <class T>
   T Test(T x, T y) {
   static_assert(sizeof T <= sizeof long, "Type is too large");
   ...
   };
```

static_assert is useful for static type checking. A certain function might fail if the implementation of an int is too small, so **static_assert** has utility outside of templates.

Working Draft - Standard for Programming Language C++ (Sec. 7.1 - Specifiers)

3.1.3.1.19.9 Strongly Typed Enums (C++0x)

C++Builder 2009 introduces scoped enums. In addition, existing enums are extended with underlying type and explicit scoping. This feature is one of the C++0x features added to C++Builder 2009.

Scoped enums are generally characterized as follows:

- Enumerators are in the scope of their enum.
- Enumerators and enums do not implicitly convert to int (as do "plain" enumerators and enums).
- Enums and their enumerators can have a defined underlying type.

Declaration

You declare a scoped enum by specifying `enum class` or `enum struct`. For example:

```
enum class A {A1, A2, A3 = 50, A4 /* = 51 */};
```

No Implicit Type Conversion

With scoped enums, there is no longer any implicit conversion to or from an integer.

Underlying Type

For scoped enums, the underlying type is well specified (the default is `int`). You can specify the underlying type of the enumeration and all the enumerators by writing : type after the enumeration name (you can specify any integral type except `wchar_t`). The following example declares an enum of underlying type `unsigned long`:

```
enum class A : unsigned long {A1 = 1, A2 = 2, Abig = 0xFFFFFFFOU };
```

Scoping

A scoped enum introduces its own scope. The names of enumerators are in the enum's scope, and are not injected into the enclosing scope. For instance:

```
enum class A { A1, A2, A3 = 100, A4 /* = 101 */ };
A a1 = A1;  // error
A a2 = A::A2;   // OK-scope specified
```

Changes to Existing Enums

In addition, existing enums are being extended as follows:

- You can now specify the underlying type of any enum, just as with scoped enums (by adding `: type` to the declaration).
- Existing enums now introduce their own scopes, just as with scoped enums. The names of enumerators are defined in the enum's scope and are also injected into the enclosing scope.

For instance:

```
enum B { B1, B2, B3 = 100, B4 /* = 101 */ };
B b1 = B1;  // ok
B b2 = B::B2;   // ok
```

Examples

The following examples demonstrate the following two things:

- The method for calling scoped enumerators
- The fact that `enum class` (and `enum struct`) cannot be specified with elaborated-type-specifiers

```
enum class E { a, b };
enum E x1 = E::a; // OK
enum class E x2 = E::a; // illegal
```

Forward Declaration of Enumerations (see page 495)

3.1.3.1.19.10 Type Specifier decltype (C++0x)

The C++0x standard includes the **decltype** keyword and operator, which represents the type of an expression. This feature is one of the C++0x features added to C++Builder 2009.

Syntax

The format of the **decltype** operator is:

```
decltype ( expression )
```

Here are the rules for evaluating `decltype(e)`:

- If e is an identifier expresson or accessing a class member, `decltype(e)` is the type of the thing designated by e. If there is no such thing, or if e is the name of a set of overloaded functions so there is ambiguity, `decltype(e)` is invalid.
- Otherwise, if e is a function call or invokes an overloaded operator, `decltype(e)` is the type returned by the function.
- Otherwise, if e is an lvalue, `decltype(e)` is a reference to `T (T&)` where T is the type of e.
- If none of the other cases apply, `decltype(e)` is the type of e.

Examples

See the embedded contents in the following examples.

```
const char *namePtr, nameChar;
decltype(namePtr);      // type is const char*
decltype(nameChar);     // type is const char
int& F(void);
decltype(F());          // type is int&

struct; D {double value; }
const D* d = new D();

decltype(d->value);    // type is double
decltype((d->value));  // type is const double&

double GetValue(int one);
long int GetValue(double d);
decltype(GetValue);     // ill-formed -- ambiguous
```

3.1.3.1.19.11 Unicode Character Types and Literals (C++0x)

C++Builder 2009 implements new character types and character literals for Unicode. These types are among the C++0x features added to C++Builder 2009.

Character Types char16_t and char32_t

Two new types represent Unicode characters:

- char16_t is a 16 bit character type. char16_t is a C++ keyword. This type could be used for UTF-16 characters.
- char32_t is a 32 bit character type. char32_t is a C++ keyword. This type can be used for UTF-32 characters.

The existing wchar_t (see page 573) type is a type for a wide character in the execution wide-character set. A wchar_t wide-character literal begins with an uppercase L (such as `L'c'`).

Character Literals u'character' and U'character'

There are two new forms to create literals of the new types:

- u'character' is a literal for a single char16_t character, such as `u'g'`. A multicharacter literal such as u'kh' is badly formed. The value of a char16_t literal is equal to its ISO 10646 code point value, provided that the code point is representable as a 16-bit cvalue. Only characters in the basic multi-lingual plane (BMP) can be represented.
- U'character' is a literal for a single char32_t character, such as `U't'`. A multicharacter literal such as U'de' is ill-formed. The value of a char32_t literal is equal to its ISO 10646 code point value.

Multibyte character literals were previously only of the form L'characters', representing one or more characters of the type wchar_t. The value of a single character wide-character literal is that character's encoding in the execution wide-character set.

3.1.3.1.20 Unicode for C++

This section contains Unicode related feature topics for C++.

Topics

Name	Description
TCHAR Mapping (see page 501)	**TCHAR**, which is declared in the header file *tchar.h*, is a **typedef** (alias) that maps either to **char** or to **wchar_t**. When you want to write portable code, you should use **TCHAR** instead of hard coding **char** or **wchar_t**. The **TCHAR maps to** option controls the floating definition of _TCHAR. Your choices are: ***_TCHAR Mapping Options***
Floating Functions (see page 502)	This topic describes how to write portable code that correctly uses the floating definitions of RTL functions. The list of floating functions is useful for choosing the correct variant of a function.
Enabling C++ Applications for Unicode (see page 507)	C++ has a unique set of Unicode-related issues that Delphi users do not have. Some of these issues are: • String constants, such as `"string constant"`, are still narrow (`char*`), so you cannot pass them to VCL functions that take **PChar** as you did before. If you prefix the constant with **L**, as in `L"string constant"`, you can pass the constant to VCL functions with a **PChar** parameter. • The C++ RTL is as wide and narrow as it always was. Unless you planned ahead and used <tchar.h> and the _txxxxxx() macros, you need to do some... more (see page 507)

3.1.3.1.20.1 TCHAR Mapping

TCHAR, which is declared in the header file *tchar.h*, is a **typedef** (alias) that maps either to **char** or to **wchar_t**. When you want to write portable code, you should use **TCHAR** instead of hard coding **char** or **wchar_t**.

The **TCHAR maps to** option controls the floating definition of _TCHAR. Your choices are:

_TCHAR Mapping Options

char	_TCHAR does not float to a wide definition.
wchar_t	Sets the UNICODE and _UNICODE defines. _TCHAR floats to the wide definitions of standard library and API functions.

To set the **TCHAR maps to** option, go to the **Project ▸ Options ▸ Directories and Conditionals** dialog box.

Use _TCHAR maps to wchar_t for VCL

The VCL is implemented in Unicode and always expects Unicode. To use the VCL, you should set **TCHAR maps to** to **wchar_t**. For example, the following code does not compile unless you have set _TCHAR to **wchar_t**:

```
TResourceStream* res =  new
    TResourceStream(HInstance, ResourceId, RT_RCDATA);
```

If _TCHAR is **char**, RT_RCDATA maps to a `char*`, but VCL expects **wchar_t**.

Use _TEXT function for Constants Strings

To ensure that constants strings float properly to ANSI or Unicode, use either the function _TEXT or _T. For example:

```
::MessageBox(0, _TEXT("The message"),
    _TEXT("The caption"), MB_OK);
```

Code Changes Are Required for Using _TCHAR maps to wchar_t

Before you can set the _TCHAR option to **wchar_t**, your project must have an entry point called either _tmain or _tWinMain. New projects created with C++Builder 2009 have these entry points by default, but for imported projects you might need to add these entry points by hand. You must also include the *tchar.h* header file, which contains the floating definitions and the entry

points that you need. For a list of the floating functions contained in *tchar.h*, see Floating Functions (see page 502).

3.1.3.1.20.2 Floating Functions

This topic describes how to write portable code that correctly uses the floating definitions of RTL functions. The list of floating functions is useful for choosing the correct variant of a function.

Example of Writing Portable Code Using _TCHAR

RTL functions are available in either ANSI/MBCS or Unicode definitions. For example, the RTL function `strlen` can be used in ANSI/MBCS mode as follows:

```
void StorePersonData(const char* name)
{
   PersistToDB(name, strlen(name));
}
```

```
A more portable way of writing this code is:
```

```
void StorePersonData(const _TCHAR* name)
{
   PersistToDB(name, _tcstrlen(name));
}
```

This example assumes that `PersistToDB` has a Unicode version. Note that for functions that are not going to change or float, you should use either **char** or **wchar_t**.

List of Floating Definitions from tchar.h

The following table is derived from the *tchar.h* header file. The **char/ANSI** column lists the floating functions that are appropriate when `_TCHAR` is mapped to `char`, the ANSI version of the function. The **wchar_t/UNICODE** column lists the functions for **wchar_t**, the **UNICODE** version of the function. The **_TCHAR/Portable** column lists the portable version of the function, which maps to the appropriate function (either the ANSI or UNICODE version) as determined by the current setting of the `_TCHAR` mapping option.

TCHAR Mapping (see page 501)

Unicode in RAD Studio

Enabling Unicode in Your Applications

Enabling C++ Applications for Unicode (see page 507)

3.1.3.1.20.3 Enabling C++ Applications for Unicode

C++ has a unique set of Unicode-related issues that Delphi users do not have. Some of these issues are:

- String constants, such as `"string constant"`, are still narrow (`char*`), so you cannot pass them to VCL functions that take **PChar** as you did before. If you prefix the constant with **L**, as in `L"string constant"`, you can pass the constant to VCL functions with a **PChar** parameter.
- The C++ RTL is as wide and narrow as it always was. Unless you planned ahead and used <tchar.h> and the _txxxxxx() macros, you need to do some work to use the wide flavor of the RTL. VCL generally uses wide string data, so you probably need to use wide RTL functions.
- The Windows API is still narrow by default. The new _TCHAR mapping option helps trememdously here, but the option is OFF by default. You need to explicitly set the _**TCHAR maps to** option on the **Project**▶**Options**▶**Directories and Conditionals** dialog box.
- You can set the codepage for **AnsiString** types with `AnsiStringT<codepage>`. The same predefined types are available that Delphi provides:
- **AnsiString** is `AnsiStringT<0>`
- **UTF8String** is `AnsiStringT<65005>`
- **RawByteString** is `AnsiStringT<0xFFFF>`

3.1.3.1.21 Handling Delphi Features in C++Builder 2009

This section contains topics describing how you can handle issues that might arise when C++Builder 2009 interacts with certain new Delphi features.

Topics

Name	Description
How to Handle Delphi Anonymous Methods in C++ (see page 508)	This topic describes some programming issues that you might encounter when dealing with anonymous methods, one of Delphi's newest features. Under the cover, Delphi implements anonymous methods types (also known as method references) via an interface that implements an `Invoke(...)` method. So a method that takes a method reference parameter in Delphi is exposed to C++ as a method that takes an interface. Here's an example:
How to Handle Delphi AnsiString Code Page Specification in C++ (see page 510)	The C++ implementation of the AnsiString type provides CodePage support similar to that available in Delphi 2009. However, while the Delphi version is implemented via extension to the language, the C++ version is implemented via a template with a non-type parameter as codepage, as in:
How to Handle Delphi Generics in C++ (see page 511)	This topic describes some programming issues that you might encounter when dealing with generics, one of Delphi's newest features. Delphi generics are exposed to C++ as templates. However, it's important to realize that the instantiations occur on the Delphi side, not in C++. Therefore, you can only use these template for types that were explicitly instantiated in Delphi code. For example, let's declare a simply generic, `TList<T>`, in Delphi:

3.1.3.1.21.1 How to Handle Delphi Anonymous Methods in C++

This topic describes some programming issues that you might encounter when dealing with anonymous methods, one of Delphi's newest features.

Under the cover, Delphi implements anonymous methods types (also known as method references) via an interface that implements an `Invoke(...)` method. So a method that takes a method reference parameter in Delphi is exposed to C++ as a method that takes an interface. Here's an example:

```
interface

type

  TRefProc = reference to function (I, J: Integer): Integer;

  TTestClass = class
    public
      function TakeRefProc(RefProc: TRefProc; I, J: Integer): Integer;
  end;
```

The following is the .hpp file generated for the above:

```
__interface TRefProc;
typedef System::DelphiInterface <TRefProc> _di_TrefProc;

__interface TRefProc  : public System::IInterface
{
public:
 virtual int __fastcall Invoke(int I, int J) = 0 ;
};

class PASCALIMPLEMENTATION TTestClass : public System::TObject
{
public:
 int __fastcall TakeRefProc(_di_TRefProc RefProc, int I, int J);
};
```

C++ code that seeks to specify a function or member function as a method reference parameter has to wrap the latter behind an interface that exposes an `Invoke()` method. A C++ template can be used to encapsulated such an interface. The following C++ code shows an example of a template that can be used to pass C++ methods or member functions as method references to Delphi.

```
enum _DummyType{};      // Parameter used as default

template <typename INTF,                        // Interface with Invoke
```

```
                typename F,                            // Function type
                typename R,                           // Return type
                typename P1 = _DummyType,  // Param #1
                typename P2 = _DummyType,  // Param #2
                typename P3 = _DummyType,  // Param #3
                typename P4 = _DummyType,  // Param #4
                typename P5 = _DummyType> // Param #5
class TMethodRef : public TInterfacedObject, public INTF

{
private:
  F callback;
public:
  TMethodRef(F _callback) : callback(_callback) {}

  HRESULT STDMETHODCALLTYPE QueryInterface (const GUID& riid, void** ppvObject)
  { return TInterfacedObject::QueryInterface (riid, ppvObject); }
  ULONG STDMETHODCALLTYPE AddRef()
  { return TInterfacedObject::_AddRef(); }
  ULONG STDMETHODCALLTYPE Release()
  { return TInterfacedObject::_Release(); }

R __fastcall Invoke(P1 p1)
  {
    return callback(p1);
  }
  R __fastcall Invoke(P1 p1, P2 p2)
  {
    return callback(p1, p2);
  }
  R __fastcall Invoke(P1 p1, P2 p2, P3 p3)
  {
    return callback(p1, p2, p3);
  }
  R __fastcall Invoke(P1 p1, P2 p2, P3 p3, P4 p4)
  {
    return callback(p1, p2, p3, p4);
  }
  R __fastcall Invoke(P1 p1, P2 p2, P3 p3, P4 p4, P5 p5)
  {
    return callback(p1, p2, p3, p4, p5);
  }
};
```

The following code shows how to use the template shown above to pass a C++ routine as a method reference.

```
// C++ function we want to pass as a method reference.
int multiplyCallback(int i, int j)
{
  return i*j;
}

void UseRefProcFlat()
{
  std::auto_ptr<TTestClass> cls(new TTestClass());
  _di_TRefProc proc = new TMethodRef<TRefProc, int (*)(int, int), int, int,
int>(multiplyCallback);
  int i = cls->TakeRefProc(proc, 10, 20);
  assert(i == 200);
}
```

You can also use the template to pass a member function as a method reference. The following code illustrates this:

```
class TMyClass {
public:
  int add(int i, int j) {
```

```
    return i+j;
  }
};
typedef int (__closure *TClosure)(int, int);

void UseRefProcMember()
{
  TMyClass myClass;

  std::auto_ptr<TTestClass> cls(new TTestClass());
  _di_TRefProc proc = new TMethodRef<TRefProc, TClosure, int, int, int>(&myClass.add);

  int i = cls->TakeRefProc(proc, 10, 20);
  assert(i == 30);
}
```

Handling AnsiString Code Page Specification (see page 510)

3.1.3.1.21.2 How to Handle Delphi AnsiString Code Page Specification in C++

The C++ implementation of the AnsiString type provides CodePage support similar to that available in Delphi 2009. However, while the Delphi version is implemented via extension to the language, the C++ version is implemented via a template with a non-type parameter as codepage, as in:

```
template AnsiStringT<unsigned short codePage>
```

Therefore, the type previously known as AnsiString type is now simply a typedef of the new AnsiStringT template, as in:

```
 typedef AnsiStringT<65001> UTF8String;

 typedef AnsiStringT<65535> RawByteString;
```

You can declare other specializations of AnsiStringT with the codepage you need.

All assignments to an AnsiStringT instance will encode the data in the type's codepage. For example, in the following code, the Unicode data assigned to the UTF8String variable is automatically UTF8-encoded:

```
const wchar_t* data = L"???????";
UTF8String utfs(data);
```

The 'utfs' variable can be passed to a function expecting a UnicodeString and the original data will be restored without any loss incurred:

```
Button1->Caption = utfs; // Set button caption to "???????";
```

Note that while the AnsiStringT handles the codepage support behind the scene, you can still explicitly set the codepage of an instance by calling the following method:

```
AnsiStringT<CP>::SetCodePage(unsigned short codePage, bool
    convert=true)
```

This method should be used carefully because it might mislead users of the instance who expect the type to contain data encoded in its default codepage.

3.1.3.1.21.3 How to Handle Delphi Generics in C++

This topic describes some programming issues that you might encounter when dealing with generics, one of Delphi's newest features.

Delphi generics are exposed to C++ as templates. However, it's important to realize that the instantiations occur on the Delphi side, not in C++. Therefore, you can only use these template for types that were explicitly instantiated in Delphi code. For example, let's declare a simply generic, `TList<T>`, in Delphi:

```
 interface

type

    MyTList<T> = class(TList<T>) // TList is a class in the Generics.Collections namespace
        FItems: array of T;
    protected
        function GetLength: Integer;
    public
        function Get(Index: Integer): T;
    published
        property Len: Integer read GetLength;
    end;

    { ScoreList derived from a TList<double>}
    ScoreList = class(MyTList<double>)
    end;
    { StringList derived from a TList<string>}
    StringList = class(MyTList<string>)
    end;

implementation

{$R *.dfm}

function MyTList<T>.GetLength: Integer;
begin
    Result := Count;
end;

  function MyTList<T>.Get(Index: Integer): T;
begin
    Result := Items[Index];
end;
```

The interface above is exposed to C++ as the following:

```
// Template declaration generated by Delphi parameterized types is
// used only for accessing Delphi variables and fields.
// Don't instantiate with new type parameters in user code.
template<typename T> class PASCALIMPLEMENTATION MyTList__1 : public
Generics_collections::TList__1<T>
{
typedef Generics_collections::TList__1<T> inherited;

private:
typedef DynamicArray<T> _MyTList__1__1;

public:
    _MyTList__1__1 FItems;

 protected:
    int __fastcall GetLength(void);

public:
    T __fastcall Get(int Index);
```

```
__published:
     __property int Len = {read=GetLength, nodefault};
public:
/* TList<T>.Create */ inline __fastcall MyTList__1(void)/* overload */ :
Generics_collections::TList__1<T>() { }
      /* TList<T>.Destroy */ inline __fastcall virtual ~MyTList__1(void) { }

};

class DELPHICLASS ScoreList;
class PASCALIMPLEMENTATION ScoreList : public MyTList__1<double>
{
typedef MyTList__1<double> inherited;

public:
/* TList<Double>.Create */ inline __fastcall ScoreList(void)/* overload */ :
MyTList__1<double>() { }
      /* TList<Double>.Destroy */ inline __fastcall virtual ~ScoreList(void) { }

};

class DELPHICLASS StringList;
class PASCALIMPLEMENTATION StringList : public MyTList__1<System::UnicodeString>
{
typedef MyTList__1<System::UnicodeString> inherited;

public:
/* TList<string>.Create */ inline __fastcall StringList(void)/* overload */ :
MyTList__1<System::UnicodeString>() { }
/* TList<string>.Destroy */ inline __fastcall virtual ~StringList(void) { }

};
```

C++ code linking with the .obj created from the above Delphi unit can use instances of `TList__1<double>` or `ScoreList`.

```
void UseScoreList()
{
  ScoreList* list = new ScoreList();

  list->Add(1.0);
  list->Add(2.0);

  int len = list->Len;
  assert(len == 2);

  delete list;
}

void UseTList__1()

{
    // C++ code can use the Generics defined in Delphi directly
    // as long as the C++ code limits itself to types for which
    // the generic was instantiated on the Delphi size. For example,
    // since test.pas uses TList<String> and TList<double> we can use
    // these here. However, if we try to use TList__1>char> we'll get
    // an error since the Delphi side did not instantiate
    // TList<AnsiChar>.
    TList__1<double>* dblList = new MyTList__1<double>();
    dblList—>Add(1.0);
    dblList—>Add(1.5);
    double d = dblList—>Get(1);
    delete dblList;
```

```
    MyTList__1<UnicodeString> *stringList = new MyTList__1<UnicodeString>();
    stringList->Add("hiya");
    stringList->Add("there");
    stringList->Add("buckeroo");
    UnicodeString dstring = stringList->Get(0);
    delete stringList;
 }
```

If C++ code attempts to use a Delphi generic for types that were not instantiated in Delphi, you'll get errors at link time. For example, the following code attempts to use `TList__1<char>` when the Delphi code did not explicitly instantiate `TList<AnsiChar>`:

```
void UseListOfChar()
{
  TList__1<char>* charList = new TList__1<char>();
charList->Add('a');
  char ch = charList->Get(1);
  delete charList;
}
```

While the code above compiles, the following errors are generated at link time:

```
[ILINK32 Error] Error: Unresolved external 'Test::MyTList__1<char>::>::' referenced from
USETEST.OBJ
[ILINK32 Error] Error: Unresolved external '__fastcall Test::MyTList__1<char>>::Add(char)'
referenced from USETEST.OBJ
[ILINK32 Error] Error: Unresolved external '__fastcall Test::MyTList__1<char>::Get(int)'
referenced from USETEST.OBJ
```

To eliminate the error, you have to make sure that the Delphi code uses the type `MyTList<AnsiChar>`.

bitand, & (see page 533)	**Category** Alternative Representations of Operators and Tokens, Operators **Syntax** **Description** The **bitand** operator is an alternative representation of the **&**operator (bitwise AND). The bitwise AND operator compares each bit of the first operand to the corresponding bit of the second operand When both bits are 1, the corresponding result bit is set to 1. Otherwise, the corresponding result bit is set to 0. In order to use the **bitand** operator, you need to check the **Enable new operator names** option (the **-Vn** compiler switch, available on the **Compatibility** page of the **Project** ▶ **Options** dialog box).
bitor, | (see page 533)	**Category** Alternative Representations of Operators and Tokens, Operators **Syntax** **Description** The **bitor** operator is an alternative representation of the **|~**operator (bitwise OR). **bitor** takes integer or enumeration operands. **bitor** may pass two or more arguments. These arguments must be character or numeric. When coded as a keyword, **bitor** can only pass two arguments. In either case, the result type is the same as the arguments: (1) unsigned if all arguments are unsigned, or (2) an integer. In order to use the **bitor** operator, you need to check the **Enable new operator names** option (the **-VM** compiler switch, available... more (see page 533)

namespace (see page 556)	**Category** C++-Specific Keywords **Description** Most real-world applications consist of more than one source file. The files can be authored and maintained by more than one developer. Eventually, the separate files are organized and linked to produce the final application. Traditionally, the file organization requires that all names that aren't encapsulated within a defined namespace (such as function or class body, or translation unit) must share the same global namespace. Therefore, multiple definitions of names discovered while linking separate modules require some way to distinguish each name. The solution to the problem of name clashes in the global scope is provided... more (see page 556)
new (see page 556)	**Category** Operators, C++-Specific Keywords **Syntax**
noreturn (see page 557)	**Category** Attributes, Keyword extensions **Syntax**
not, ! (see page 557)	**Category** Alternative Representations of Operators and Tokens, Operators **Syntax** **Description** The **not** operator is an alternative representation of the **!**operator (logical negation). **not** returns *true* if its operand is *false*, and *false* if its operand is *true*. If an integer is 1, the expression of !1 indicates that the number is other than 1 So that is a true statement. **not** can also be used for strings as well. The expression !Smith indicates that the person's name is other than Smith.. **not** inverts the bits of the expression. In order to use the **not** operator, you need... more (see page 557)
not_eq, != (see page 558)	**Category** Alternative Representations of Operators and Tokens, Operators **Syntax** **Description** The **not_eq** operator is an alternative representation of **!=** (bitwise inequality). It tests for logical inequivalence. **not_eq** compares two expressions to determine whether or not they are the same. Therefore, 7 != 8 returns true, while 7 != 7 returns false. The same is true for any expression such as Smith != Smith. which returns false. In order to use the **not_eq** operator, you need to check the **Enable new operator names** option (the **-VM** compiler switch, available on the **Compatibility** page of the **Project** ▶ **Options** dialog box).

nullptr (see page 558)	**Category** Reserved Words **Syntax**
operator (see page 558)	**Category** Operators, C++-Specific Keywords **Syntax**
or, || (see page 559)	**Category** Alternative Representations of Operators and Tokens, Operators **Syntax** **Description** The **or** operator is an alternative representation of the **||** operator (logical OR). Only two statements can be evaluated at a time. **or** returns true if two values are different, such as 2 or 6. **or** returns false if both values are the same, such as 10 and 10. In order to use the **or** operator, you need to check the **Enable new operator names** option (the **-VM** compiler switch, available on the **Compatibility** page of the **Project** ▶ **Options** dialog box).
or_eq, |= (see page 559)	**Category** Alternative Representations of Operators and Tokens, Operators **Syntax** **Description** The **or_eq** operator is an alternative representation of **|=**(bitwise inclusive OR). **or_eq** tests for logical equivalence or bitwise equality. **or_eq** operates on two values. When the first value or the second value is 1, true is returned. When the values are 0, false is returned. In order to use the **not_eq** operator, you need to check the **Enable new operator names** option (the **-VM** compiler switch, available on the **Compatibility** page of the **Project** ▶ **Options** dialog box).

signed (see page 563)	**Category** Type specifiers **Syntax**

sizeof (see page 563)	**Category** Operators **Description** The **sizeof** operator has two distinct uses: **sizeof** unary-expression **sizeof** (type-name) The result in both cases is an integer constant that gives the size in bytes of how much memory space is used by the operand (determined by its type, with some exceptions). The amount of space that is reserved for each type depends on the machine. In the first use, the type of the operand expression is determined without evaluating the expression (and therefore without side effects). When the operand is of type **char** (**signed** or **unsigned**), **sizeof** gives the result 1. When the... more (see page 563)

void (see page 572)	**Category** Special types **Syntax**
volatile (see page 573)	**Category** Modifiers **Syntax**
wchar_t (see page 573)	**Category** C++-Specific Keywords, Type specifiers **Syntax**
while (see page 574)	**Category** Statements **Syntax**
xor, ^ (see page 574)	**Category** Alternative Representations of Operators and Tokens, Operators **Syntax** **Description** The **xor** operator is an alternative representation of the **^** operator (bitwise xor). It returns a Boolean true result if just one of its operands is true. This is in opposition to an inclusive **or** which denotes that both statements must be integers for a true statement to be returned. If 2 or 8.25 are stated to be integers, a true statement will be returned even though 8.25 is a decimal. If Jack and Jill are both stated to be male, a true statement would be returned even though Jill... more (see page 574)
__classmethod (see page 574)	**Category** Modifiers, Keyword extensions **Syntax**
alignas (see page 575)	**Category** C++-Specific Keywords **Syntax**
and_eq, &= (see page 575)	**Category** Alternative Representations of Operators and Tokens, Operators **Syntax** **Description** The **and_eq** operator is an alternative representation of the **&=** assignment operator (bitwise AND). The value of the first operand is added to the value of the second operand, and the result is stored in the first operand. In order to use the **and_eq** operator, you need to check the **Enable new operator names** option (the **-Vn** compiler switch, available on the **Compatibility** page of the **Project** ▶ **Options** dialog box).

3.1.3.2.1 __automated

Category

Keyword extensions

Syntax

```
_automated: <declarations>
```

Description

The visibility rules for automated members are identical to those of public members. The only difference between automated and public members is that OLE automation information is generated for member functions and properties that are declared in an automated section. This OLE automation type information makes it possible to create OLE Automation servers.

- For a member function, the types of all member function parameters and the function result (if any) must be automatable. Likewise, for a property, the property type and the types of any array property parameters must be automatable. The automatable types are: Currency, OleVariant, DelphiInterface, double, int, float, short, String, TDateTime, Variant, and unsigned short. Declaring member functions or properties that use non-automatable types in an __automated section results in a compile-time error.
- Member function declarations must use the __fastcall calling convention.
- Member functions can be virtual.

- Member functions may add __dispid(constant int expression) after the closing parenthesis of the parameter list.
- Property declarations can only include access specifiers (__dispid, read, and write). No other specifiers (index, stored, default, nodefault) are allowed.
- Property access specifiers must list a member function identifier. Data member identifiers are not allowed.
- Property access member functions must use the __fastcall calling convention.
- Property overrides (property declarations that don't include the property type) are not allowed.

See Also

__dispid (see page 525)

__closure (see page 523)

__property (see page 527)

__published (see page 528)

3.1.3.2.2 __classid

Category

Operators, Keyword extensions

Syntax

```
__classid(classType)
```

Description

The __**classid** operator was added to support the VCL framework. Normally, programmers should not directly use this operator. For more information, see the keyword extensions.

See Also

__classmethod (see page 574)

__property (see page 527)

3.1.3.2.3 __closure

Category

Keyword extensions

Syntax

```
<type> ( __closure * <id> ) (<param list>);
```

Description

The keyword __**closure** was added to support the VCL framework and is used when declaring event handler functions. For more information, see the keyword extensions.

See Also

__property (see page 527)

3.1.3.2.4 __declspec

Category

Modifiers, Keyword extensions, Storage class specifiers

Syntax

```
__declspec(<decl-modifier>)
```

Description

For a list of **__declspec** keyword arguments used for the VCL framework, see VCL class declarations.

Use the **__declspec** keyword to indicate the storage class attributes for a variable or function.

The **__declspec** keyword extends the attribute syntax for storage class modifiers so that their placement in a declarative statement is more flexible. The **__declspec** keyword and its argument can appear anywhere in the declarator list, as opposed to the old-style modifiers which could only appear immediately preceding the identifier to be modified.

```
__export void f(void);                      // illegal
void __export f(void)                       // correct
void __declspec(dllexport) f(void);         // correct
__declspec(dllexport)void f(void);          // correct
class __declspec(dllexport) ClassName { }   // correct
```

In addition to the arguments listed above, the supported decl-modifier arguments are:

- dllexport
- dllimport
- naked
- noreturn
- nothrow
- novtable
- property
- selectany
- thread
- uuid

These arguments are equivalent to the following storage class attribute keywords.

Argument	Comparable keyword
dllexport	__export
dllimport	__import
thread	__thread

See Also

_export (see page 530)

import (see page 554)

__declspec(dllexport) (see page 540)

__declspec(dllimport) (see page 541)

__declspec(naked) (see page 541)

__declspec(noreturn) (see page 541)

__declspec(nothrow) (see page 542)

__declspec(novtablet) (see page 542)

__declspec(property) (see page 543)

__declspec(selectany) (see page 543)

__declspec(thread) (see page 544)

__declspec(uuid) (see page 544)

3.1.3.2.5 __dispid

Category

Modifiers

Syntax

```
__dispid(constant int expression)
```

Description

A member function that has been declared in the __automated section of a class can include an optional __dispid(constant int expression) directive. The directive must be declared after the closing parenthesis of the parameter list.

The constant int expression gives the Automation dispatch ID of the member function or property. If a dispid directive is not used, the compiler automatically picks a number one larger than the largest dispatch ID used by any member function or property in the class and its base classes.

Specifying an already-used dispatch ID in a dispid directive causes a compile-time error.

See Also

__closure (see page 523)

__property (see page 527)

3.1.3.2.6 __except

Category

Statements, Keyword extensions

Syntax

```
__except (expression) compound-statement
```

Description

The __except keyword specifies the action that should be taken when the exception specified by expression has been raised.

See Also

__finally (see page 550)

__try (see page 529)

3.1.3.2.7 __inline

Category

Keyword extensions

Syntax

```
__inline <datatype> <class>_<function> (<parameters>) { <statements>; }
```

Description

Use the **__inline** keyword to declare or define C or C++ inline functions. The behavior of the **__inline** keyword is identical to that of the **inline** keyword, which is only supported in C++.

Inline functions are best reserved for small, frequently used functions.

3.1.3.2.8 __int8, __int16, __int32, __int64, Unsigned __int64, Extended Integer Types

Category

Keyword extensions

Description

You can specify the size for integer types. You must use the appropriate suffix when using extended integers.

Type	Suffix	Example	Storage
__int8	i8	__int8 c = 127i8;	8 bits
__int16	i16	__int16 s = 32767i16;	16 bits
__int32	i32	__int32 i = 123456789i32;	32 bits
__int64	i64	__int64 big = 12345654321i64;	64 bits
unsigned __int64	ui64	unsigned __int64 hugeInt = 1234567887654321ui64;	64 bits

3.1.3.2.9 __msfastcall

Category

Modifiers, Keyword extensions

Syntax

```
__msfastcall <function-name>
```

Description

This calling convention emulates the Microsoft implementation of the fastcall calling convertion. The first two DWORD or smaller arguments are passed in ECX and EDX registers, all other arguments are passed from right to left. The called function is responsible for removing these arguments from the stack.

3.1.3.2.10 __msreturn

Category

Modifiers, Keyword extensions

Syntax

```
__msreturn <function-name>
```

Description

This calling convention is used for Microsoft compatible __**fastcall** calling convention return values. Structures with a size that is greater than 4 bytes and less than 9 bytes, and having at least one of its members sized 4 bytes or larger, are returned in EAX/EDX.

3.1.3.2.11 __property

Category

Keyword extensions

Syntax

```
<property declaration> ::=
     __property <type> <id> [ <prop dim list> ] = "{" <prop attrib list> "}"

<prop dim list> ::=
     "[" <type> [ <id> ] "]" [ <prop dim list> ]

<prop attrib list> ::=
     <prop attrib> [ , <prop attrib list> ]

<prop attrib> ::=
     read = <data/function id> |
     write = <data/function id> |
     stored = <data/function id> |
     stored = <boolean constant> |
     default = <constant> |
     nodefault |
     index = <const int expression>
```

Description

The __**property** keyword was added to support the VCL

See Also

__closure (see page 523)

3.1.3.2.12 __published

Category

Keyword extensions

Syntax

```
__published: <declarations>
```

Description

The **__published** keyword was added to support the VCL.

See Also

__closure (see page 523)

__dispid (see page 525)

3.1.3.2.13 __rtti, -RT Option

Category (__rtti keyword)

Modifiers, C++ Keyword Extensions, C++-Specific Keywords

Description

Runtime type identification is enabled by default. You can disable RTTI on the C++ page of the Project Options dialog box. From the command-line, you can use the **-RT-** option to disable it or **-RT** to enable it.

If RTTI is disabled, or if the argument to **typeid** is a pointer or a reference to a non-polymorphic class, **typeid** returns a reference to a **const** type_info object that describes the declared type of the pointer or reference, and not the actual object that the pointer or reference is bound to.

In addition, even when RTTI is disabled, you can force all instances of a particular class and all classes derived from that class to provide polymorphic runtime type identification (where appropriate) by using the **__rtti** keyword in the class definition.

When runtime type identification is disabled, if any base class is declared **__rtti**, then all polymorphic base classes must also be declared **__rtti**.

```
struct __rtti S1 { virtual s1func(); };  /* Polymorphic */
struct __rtti S2 { virtual s2func(); };  /* Polymorphic */
struct X : S1, S2 { };
```

If you turn off the RTTI mechanism, type information might not be available for derived classes. When a class is derived from multiple classes, the order and type of base classes determines whether or not the class inherits the RTTI capability.

When you have polymorphic and non-polymorphic classes, the order of inheritance is important. If you compile the following declarations without RTTI, you should declare X with the **__rtti** modifier. Otherwise, switching the order of the base classes for the class X results in the compile-time error "Can't inherit non-RTTI class from RTTI base 'S1'."

```
struct __rtti S1 { virtual func(); };   /* Polymorphic class */
struct S2 { };                           /*  Non-polymorphic class */
struct __rtti X : S1, S2 { };
```

Note: The class X is explicitly declared with __rtti

. This makes it safe to mix the order and type of classes. In the following example, class X inherits only non-polymorphic classes. Class X does not need to be declared **__rtti**.

```
struct __rtti S1 {  };   // Non-polymorphic class
```

```
struct S2 { };
struct X : S2, S1 { };   // The order is not essential
```

Neither the __**rtti** keyword, nor enabling RTTI will make a static class into a polymorphic class.

See Also

Runtime Type Identification (RTTI) Overview (see page 453)

Runtime Type Identification And Destructors (see page 454)

3.1.3.2.14 __thread, Multithread Variables

Category

Keyword extensions

Description

The keyword __**thread** is used in multithread programs to preserve a unique copy of global and static class variables. Each program thread maintains a private copy of a __**thread** variable for each thread.

The syntax is Type __**thread** variable__name. For example

```
int __thread x;
```

This statement declares an integer type variable that will be global but private to each thread in the program in which the statement occurs.

3.1.3.2.15 __try

Category

Statements, Keyword extensions

Syntax

```
__try compound-statement handler-list__try
__try compound-statement termination-statement
```

Description

The __**try** keyword is supported in both C and C++ programs. You can also use try in C++ programs.

A block of code in which an exception can occur must be prefixed by the keyword __**try**. Following the try keyword is a block of code enclosed by braces. This indicates that the program is prepared to test for the existence of exceptions. If an exception occurs, the normal program flow is interrupted. The program begins a search for a handler that matches the exception. If the exception is generated in a C module, it is possible to handle the structured exception in either a C module or a C++ module.

If a handler can be found for the generated structured exception, the following actions can be taken:

- Execute the actions specified by the handler
- Ignore the generated exception and resume program execution
- Continue the search for some other handler (regenerate the exception)

If no handler is found, the program will call the terminate function. If no exceptions are thrown, the program executes in the normal fashion.

See Also

catch (see page 536)

__finally (see page 550)

3.1.3.2.16 _export, __export

Category

Modifiers, Keyword extensions

Form 1

```
class _export <class name>
```

Form 2

```
return_type _export <function name>
```

Form 3

```
data_type _export <data name>
```

Description

These modifiers are used to export classes, functions, and data.

The linker enters functions flagged with **_export** or **__export** into an export table for the module.

Using **_export** or **__export** eliminates the need for an EXPORTS section in your module definition file.

Functions that are not modified with **_export** or **__export** receive abbreviated prolog and epilog code, resulting in a smaller object file and slightly faster execution.

Note: If you use _export

or **__export** to export a function, that function will be exported by name rather than by ordinal (ordinal is usually more efficient). If you want to change various attributes from the default, you'll need a module definition file.

3.1.3.2.17 _fastcall, __fastcall

Category

Modifiers, Keyword extensions

Syntax

```
return-value _fastcall function-name(parm-list)
return-value __fastcall function-name(parm-list)
```

Description

Use the **__fastcall** modifier to declare functions that expect parameters to be passed in registers. The first three parameters are passed (from left to right) in EAX, EDX, and ECX, if they fit in the register. The registers are not used if the parameter is a floating-point or struct type.

Note: All VCL class member functions and form class member functions must use the __fastcall

convention. The compiler treats this calling convention as a new language specifier, along the lines of _cdecl and _pascal

Functions declared using **_cdecl** or **_pascal** cannot have the **_fastcall** modifier because they use the stack to pass parameters. Likewise, the **__fastcall** modifier cannot be used together with _export.

The compiler prefixes the **__fastcall** function name with an at-sign ("@"). This prefix applies to both unmangled C function names and to mangled C++ function names.

For Microsoft C++ style **__fastcall** implementation, see __msfastcall and __msreturn.

Note: Note: The __fastcall modifier is subject to name mangling. See the description of the -VC option.

3.1.3.2.18 _stdcall, __stdcall

Category

Modifiers, Keyword extensions

Syntax

```
__stdcall <function-name>
_stdcall <function-name>
```

Description

The **_stdcall** and **__stdcall** keywords force the compiler to generate function calls using the Standard calling convention. Functions must pass the correct number and type of arguments; this is unlike normal C use, which permits a variable number of function arguments.

Such functions comply with the standard WIN32 argument-passing convention.

Note: Note: The __stdcall modifier is subject to name mangling. See the description of the -VC option.

3.1.3.2.19 alignof

Category

Operators, Keyword extensions

Syntax

```
alignof(type);
```

Description

The **alignof** operator tells you the alignment of a type. This feature is one of the C++0x features added to C++Builder 2009.

The result is an integer constant of type `std::size_t`. The value indicates the boundaries on which elements of that type are aligned in memory. An alignment of 2 means that the type must begin on even memory addresses, for instance. A typical value for `alignof(double)` might be 8.

Applying **alignof** to a reference type yields the alignment of the referenced type. If you apply **alignof** to an array type, you get the alignment of its element's type.

See Also

C++0x Features (C++Builder 2009) (see page 462)

Working Draft - Standard for Programming Language C++ (Sec. 5.3.6)

alignof Operator (C++0x) (see page 463)

3.1.3.2.20 and, &&

Category

Alternative Representations of Operators and Tokens, Operators

Syntax

Description

The **and** operator is an alternative representation of the **&&** operator (binary or logical AND).

If both operands have a value of true, the result has the value true. Otherwise, the result has the value false. Both operands are implicitly converted to bool and the result type is bool.

Unlike the **&** (bitwise AND) operator, the **&&** operator guarantees left-to-right evaluation of the operands. If the left operand evaluates to 0 (or false), the right operand is not evaluated.

Both the **and** and **&&** operators short-circuit (that is, do not evaluate the second operand if the first evaluates as false). Thus, it is both valid and safe to test for a null pointer, as in the following example:

In order to use the **and** operator, you need to check the **Enable new operator names** option (the **-Vn** compiler switch, available on the **Compatibility** page of the **Project** ▸ **Options** dialog box).

Example of and

```
bool test( int * p ) {
  return (p != 0) and (*p > 5);
};
}
```

Substituting **&&** for **and** is also valid.

Overloading && or and

You can overload the && operator as well as the alternative representation, **and**. Keep in mind that when the operator is overloaded, the logic is not short-circuited, and the empty pointer test is not safe. Here is an example demonstrating how to overload **and**:

```
struct example {   bool operator and ( const example & ) {return true;}// same as operator &&}
```

Using && in rvalue References

As part of the new C++0x standard, C++Builder now supports rvalue references. An rvalue reference is formed by placing an && (but not an **and**) after a type in a declaration, as follows:

```
Apt a;Apt&& a_ref1 = a;
```

A major difference between the familiar lvalue reference and the new rvalue reference is that rvalue references can bind to a temporary (that is, an rvalue), but an lvalue reference (at least one that is not a const) cannot bind to an rvalue.

3.1.3.2.21 asm, _asm, __asm

Category

Keyword extensions, C++-Specific Keywords

Syntax

```
asm <opcode> <operands> <; or newline>_asm__asm
_asm <opcode> <operands> <; or newline>
__asm <opcode> <operands> <; or newline>
```

Description

Use the **asm, _asm**, or **__asm** keyword to place assembly language statements in the middle of your C or C++ source code. Any C++ symbols are replaced by the appropriate assembly language equivalents.

You can group assembly language statements by beginning the block of statements with the **asm** keyword, then surrounding the statements with braces ({}).

3.1.3.2.22 auto

Category

Storage class specifiers

Syntax

```
[auto] <data-definition> ;
```

Description

Use the **auto** modifer to define a local variable as having a local lifetime.

This is the default for local variables and is rarely used.

3.1.3.2.23 bitand, &

Category

Alternative Representations of Operators and Tokens, Operators

Syntax

Description

The **bitand** operator is an alternative representation of the **&**operator (bitwise AND).

The bitwise AND operator compares each bit of the first operand to the corresponding bit of the second operand When both bits are 1, the corresponding result bit is set to 1. Otherwise, the corresponding result bit is set to 0.

In order to use the **bitand** operator, you need to check the **Enable new operator names** option (the **-Vn** compiler switch, available on the **Compatibility** page of the **Project**▸**Options** dialog box).

3.1.3.2.24 bitor, |

Category

Alternative Representations of Operators and Tokens, Operators

Syntax

Description

The **bitor** operator is an alternative representation of the **|~**operator (bitwise OR).

bitor takes integer or enumeration operands. **bitor** may pass two or more arguments. These arguments must be character or numeric.

When coded as a keyword, **bitor** can only pass two arguments. In either case, the result type is the same as the arguments: (1) unsigned if all arguments are unsigned, or (2) an integer.

In order to use the **bitor** operator, you need to check the **Enable new operator names** option (the **-VM** compiler switch, available on the **Compatibility** page of the **Project**▸**Options** dialog box).

3.1.3.2.25 bool, false, true

Category

C++-Specific Keywords

Syntax

```
bool <identifier>;
```

Description

Use **bool** and the literals **false** and **true** to perform Boolean logic tests.

The **bool** keyword represents a type that can take only the value **false** or **true**. The keywords **false** and **true** are Boolean literals with predefined values. **false** is numericallly zero and **true** is numerically one. These Boolean literals are rvalues; you cannot make an assignment to them.

You can convert an rvalue that is of type **bool** to an rvalue that is **int** type. The numerical conversion sets **false** to zero and **true** becomes one.

You can convert arithmetic, enumeration, pointer, or pointer to member rvalue types to an rvalue of type **bool**. A zero value, null pointer value, or null member pointer value is converted to **false**. Any other value is converted to **true**.

3.1.3.2.26 break

Category

Statements

Syntax

Description

Use the **break** statement within loops to pass control to the first statement following the innermost **switch**, **for**, **while**, or **do** block.

Example

This example illustrates the use of keywords **break**, **case**, **default**, **return**, and **switch**.

```
#include <iostream>

using namespace std;

int main(int argc, char* argv[])
{
  char ch;

  cout << "PRESS a, b, OR c. ANY OTHER CHOICE WILL TERMINATE THIS PROGRAM." << endl;
  for ( /* FOREVER */; cin >> ch; )
    switch (ch)
    {
      case 'a' :    /* THE CHOICE OF a HAS ITS OWN ACTION. */
        cout << endl << "Option a was selected." << endl;
        break;
      case 'b' :    /* BOTH b AND c GET THE SAME RESULTS. */
      case 'c' :
        cout << endl << "Option b or c was selected." << endl;
        break;
      default :
        cout << endl << "NOT A VALID CHOICE!  Bye ..." << endl;
        return(-1);
    }
}
```

See Also

continue (see page 540)

do (see page 546)

for (see page 552)

while (see page 574)

case (see page 535)

default (see page 545)

switch (see page 567)

3.1.3.2.27 case

Category

Statements

Syntax

```
switch ( <switch variable> ){casebreakdefault
case <constant expression> : <statement>; [break;]
    .
    .
    .
default : <statement>;
}
```

Description

Use the **case** statement in conjunction with switches to determine which statements evaluate.

The list of possible branch points within <statement> is determined by preceding substatements with

```
case <constant expression> : <statement>;
```

where <constant expression> must be an **int** and must be unique.

The <constant expression> values are searched for a match for the <switch variable>.

If a match is found, execution continues after the matching **case** statement until a **break** statement is encountered or the end of the **switch** statement is reached.

If no match is found, control is passed to the **default** case.

Note: It is illegal to have duplicate case

constants in the same **switch** statement. **Example**

This example illustrates the use of keywords **break**, **case**, **default**, **return**, and **switch**.

```
#include <iostream>

using namespace std;

int main(int argc, char* argv[])
{
  char ch;

  cout << "PRESS a, b, OR c. ANY OTHER CHOICE WILL TERMINATE THIS PROGRAM." << endl;
  for ( /* FOREVER */; cin >> ch; )
    switch (ch)
    {
      case 'a' :    /* THE CHOICE OF a HAS ITS OWN ACTION. */
        cout << endl << "Option a was selected." << endl;
        break;
```

```
        case 'b' :    /* BOTH b AND c GET THE SAME RESULTS. */
        case 'c' :
          cout << endl << "Option b or c was selected." << endl;
          break;
        default :
          cout << endl << "NOT A VALID CHOICE!  Bye ..." << endl;
          return(-1);
      }
  }
```

See Also

break (see page 534)

default (see page 545)

switch (see page 567)

3.1.3.2.28 catch

Category

Statements, C++-Specific Keywords

Syntax

```
catch (exception-declaration) compound-statement
```

Description

The exception handler is indicated by the **catch** keyword. The handler must be used immediately after the statements marked by the try keyword. The keyword **catch** can also occur immediately after another **catch**. Each handler will only evaluate an exception that matches, or can be converted to, the type specified in its argument list.

3.1.3.2.29 cdecl, _cdecl, __cdecl

Category

Modifiers, Keyword extensions

Syntax

```
cdecl <data/function definition> ;_cdecl__cdecl
_cdecl <data/function definition> ;
__cdecl <data/function definition> ;
```

Description

Use a **cdecl**, **_cdecl**, or **__cdecl** modifier to declare a variable or a function using the C-style naming conventions (case-sensitive, with a leading underscore appended). When you use **cdecl**, **_cdecl**, or **__cdecl** in front of a function, it affects how the parameters are passed (parameters are pushed right to left, and the caller cleans up the stack). The **__cdecl** modifier overrides the compiler directives and IDE options.

The **cdecl**, **_cdecl**, and **__cdecl** keywords are specific to CodeGear C++.

3.1.3.2.30 char

Category

Type specifiers

Syntax

```
[signed|unsigned] char <variable_name>
```

Description

Use the type specifier **char** to define a character data type. Variables of type **char** are 1 byte in length.

A **char** can be signed, unsigned, or unspecified. By default, **signed char** is assumed.

Objects declared as characters (**char**) are large enough to store any member of the basic ASCII character set.

3.1.3.2.31 char16_t

Category

C++-Specific Keywords, Type specifiers

Syntax

```
char16_t <identifier>;
```

Description

In C++ programs, **char16_t** is a fundamental data type that can represent a 16 bit character type. This type could be used for UTF-16 characters. You can create a **char16_t** type with `u'<character>'`, which is a literal for a single **char16_t** character

3.1.3.2.32 char32_t

Category

C++-Specific Keywords, Type specifiers

Syntax

```
char32_t <identifier>;
```

Description

In C++ programs, **char32_t** is a fundamental data type that can represent a 32 bit character type. This type could be used for UTF-32 characters. You can create a **char32_t** type with `U'<character>'`, which is a literal for a single **char32_t** character

3.1.3.2.33 class

Category

C++-Specific Keywords, Type specifiers

Syntax

```
<classkey> <classname> <baselist> { <member list> }
```

- <classkey> is either a class**,** struct, or union.
- <classname> can be any name unique within its scope.
- <baselist> lists the base class(es) that this class derives from. <baselist> is optional
- <member list> declares the class's data members and member functions.

Description

Use the **class** keyword to define a C++ class.

Within a class:

- the data are called data members
- the functions are called member functions

See Also

Private (see page 560)

Protected (see page 560)

public (see page 561)

3.1.3.2.34 compl, ~

Category

Alternative Representations of Operators and Tokens, Operators

Syntax

Description

The **compl** operator is an alternative representation of the **~**operator (bitwise NOT).

The **compl** operator is the abbreviation for complement.

compl Inverts true to false and false to true, The tilde (~) is placed in front of the integer used for the complement.

The complement of 1 would be 0, and vice versa.

Besides an integer, ~ also outputs an enumeration type; this can be the result of the one's complement of the operand. Integral calculations are performed.

The type of the result is the type of the promoted operand.

There can be ambiguity in the unary expression ~X(), where X is a class-name. The ambiguity is resolved in favor of treating ~ as a unary complement rather than treating ~X as a destructor.

In order to use the **compl** operator, you need to check the **Enable new operator names** option (the **-VM** compiler switch, available on the **Compatibility** page of the **Project**▸**Options** dialog box).

3.1.3.2.35 const

Category

Modifiers

Syntax

```
const <variable name> [ = <value> ];
<function name> ( const <type>*<variable name> ;)
<function name> const;
```

Description

Use the **const** modifier to make a variable value unmodifiable.

Use the **const** modifier to assign an initial value to a variable that cannot be changed by the program. Any future assignments to a **const** result in a compiler error.

A **const** pointer cannot be modified, though the object to which it points can be changed. Consider the following examples.

```
const float pi   = 3.14;

// When used by itself, const is equivalent to int.
const  maxint  = 12345;

// A constant pointer
char *const str1 = "Hello, world";

// A pointer to a constant character string.
char const *str2 = "CodeGear Corporation";
```

Given these declarations, the following statements are illegal.

```
pi   = 3.0;         // Assigns a value to a const.
i     = maxint++;   // Increments a const.
str1 = "Hi, there!" // Points str1 to something else.
```

Using the const Keyword in C++ Programs

C++ extends **const** to include classes and member functions. In a C++ class definition, use the **const** modifier following a member function declaration. The member function is prevented from modifying any data in the class.

A class object defined with the **const** keyword attempts to use only member functions that are also defined with **const**. If you call a member function that is not defined as **const**, the compiler issues a warning that a non-const function is being called for a **const** object. Using the **const** keyword in this manner is a safety feature of C++.

Warning: A pointer can indirectly modify a **const** variable, as in the following:

```
*(int *)&my_age = 35;
```

If you use the **const** modifier with a pointer parameter in a function's parameter list, the function cannot modify the variable that the pointer points to. For example,

```
int printf (const char *format, ...);
```

printf is prevented from modifying the format string.

See Also

mutable (see page 555)

3.1.3.2.36 const_cast (typecast Operator)

Category

C++-Specific Keywords

Syntax

```
const_cast< T > (arg)
```

Description

Use the **const_cast** operator to add or remove the **const** or **volatile** modifier from a type.

In the statement, const_cast< T > (arg), T and arg must be of the same type except for **const** and **volatile** modifiers. The cast is resolved at compile time. The result is of type T. Any number of const or volatile modifiers can be added or removed with a single **const_cast** expression.

A pointer to **const** can be converted to a pointer to non-**const** that is in all other respects an identical type. If successful, the resulting pointer refers to the original object.

A **const** object or a reference to **const** cast results in a non-**const** object or reference that is otherwise an identical type.

The **const_cast** operator performs similar typecasts on the **volatile** modifier. A pointer to volatile object can be cast to a pointer

to non-**volatile** object without otherwise changing the type of the object. The result is a pointer to the original object. A **volatile**-type object or a reference to **volatile**-type can be converted into an identical non-**volatile** type.

See Also

Dynamic_cast (typecast Operator) (see page 547)

Reinterpret_cast (typecast Operator) (see page 561)

3.1.3.2.37 continue

Category

Statements

Syntax

```
continue;
```

Description

Use the **continue** statement within loops to pass control to the end of the innermost enclosing end brace belonging to a looping construct, such as **for** or **while**; at which point the loop continuation condition is re-evaluated.

Example

This example illustrates the use of the keyword **continue**.

```
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  float array[20];

  // Code to initialize array...
  for (int i = 0; i < 20; i++)
  {
    array[i] = random(i + 20);
  }
  array[6] = 0;

        for (int i = 0; i < 20; i++)
  {
    if (array[i] == 0)
      continue;
    array[i] = 1/array[i];
    ListBox1->Items->Add(array[i]);
  }
}
```

See Also

for (see page 552)

while (see page 574)

3.1.3.2.38 __declspec(dllexport)

Category

Modifiers, Keyword extensions, Storage class specifiers

Syntax

```
__declspec( dllexport ) declarator
```

The

dllexport storage-class attribute is used for Microsoft C and C++ language compatibility. This attribute enables you to export functions, data, and objects from a DLL. This attribute explicitly defines the DLL's interface to its client, which can be the executable file or another DLL. Declaring functions as **dllexport** eliminates the need for a module-definition (.DEF) file, at least with respect to the specification of exported functions.

Note: dllexport

replaces the __**export** keyword.

3.1.3.2.39 __declspec(dllimport)

Category

Modifiers, Keyword extensions, Storage class specifiers

Syntax

```
__declspec( dllimport ) declarator
```

The **dllimport** storage-class attribute is used for Microsoft C and C++ language compatability. This attribute enables you to import functions, data, and objects to a DLL

Note: Note

: **dllimport** replaces the __**import** keyword.

3.1.3.2.40 __declspec(naked)

Category

Modifiers, Keyword extensions, Storage class specifiers

Syntax

```
__declspec( naked ) declarator
```

Use of the naked argument suppresses the prolog/epilog code. Be aware when using __**declspec(naked)** that it does not set up a normal stack frame. A function with __**declspec(naked)** will not preserve the register values that are normally preserved. It is the programmer's responsibility to conform to whatever conventions the caller of the function expects.

You can use this feature to write your own prolog/epilog code using inline assembler code. Naked functions are particularly useful in writing virtual device drivers.

The **naked** attribute is relevant only to the definition of a function and is not a type modifier.

Example

This code defines a function with the **naked** attribute:

```
// Example of the naked attribute
__declspec( naked ) int func( formal_parameters )
{
// Function body
}
```

3.1.3.2.41 __declspec(noreturn)

Category

Modifiers, Keyword extensions, Storage class specifiers

Syntax

```
__declspec( noreturn ) declarator
```

This **__declspec** attribute tells the compiler that a function does not return. As a consequence, the compiler knows that the code following a call to a **__declspec(noreturn)** function is unreachable.

If the compiler finds a function with a control path that does not return a value, it generates a warning. If the control path cannot be reached due to a function that never returns, you can use **__declspec(noreturn)** to prevent this warning or error.

Example

Consider the following code. The **else** clause does not contain a return statement, so the programmer declares fatal as **__declspec(noreturn)** to avoid an error or warning message.

```
__declspec(noreturn) extern void fatal ()
{
   // Code omitted
}
int foo()
{
   if(...)
      return 1;
   else if(...)
      return 0;
   else
      fatal();
}
```

3.1.3.2.42 __declspec(nothrow)

Category

Modifiers, Keyword extensions, Storage class specifiers

Syntax

```
__declspec( nothrow ) declarator
```

This is a **__declspec** extended attribute that can be used in the declaration of functions. This attribute tells the compiler that the declared function and the functions it calls never throw an exception. With the synchronous exception handling model, now the default, the compiler can eliminate the mechanics of tracking the lifetime of certain unwindable objects in such a function, and significantly reduce the code size.

The following three declarations are equivalent:

```
#define WINAPI __declspec(nothrow) __stdcall
void WINAPI foo1();
void __declspec(nothrow) __stdcall foo2();
void __stdcall foo3() throw();
```

Using **void __declspec(nothrow) __stdcall foo2();** has the advantage that you can use an API definition, such as the illustrated by the **#define** statement, to easily specify nothrow on a set of functions. The third declaration, **void __stdcall foo3() throw();** is the syntax defined by the C++ standard.

3.1.3.2.43 __declspec(novtable)

Category

Modifiers, Keyword extensions, Storage class specifiers

Syntax

```
__declspec( novtable ) declarator
```

This form of **_declspec** can be applied to any class declaration, but should only be applied to pure interface classes, that is classes that will never be instantiated on their own. The **_declspec** stops the compiler from generating code to initialize the vfptr in the constructor(s) and destructor of the class. In many cases, this removes the only references to the vtable that are associated with the class and, thus, the linker will remove it. Using this form of **_declspec** can result in a significant reduction in code size

3.1.3.2.44 __declspec(property)

Category

Modifiers, Keyword extensions, Storage class specifiers

Syntax

```
__declspec( property( get=get_func_name ) ) declarator
__declspec( property( put=put_func_name ) ) declarator
__declspec( property( get=get_func_name, put=put_func_name ) ) declarator
```

This attribute can be applied to non-static “virtual data members” in a class or structure definition. The compiler treats these “virtual data members” as data members by changing their references into function calls.

When the compiler sees a data member declared with this attribute on the right of a member-selection operator (“**.**” or “**->**“), it converts the operation to a **get** or **put** function, depending on whether such an expression is an l-value or an r-value. In more complicated contexts, such as “**+=**“, a rewrite is performed by doing both **get** and **put**.

This attribute can also be used in the declaration of an empty array in a class or structure definition.

Example

__**declspec**(property(get=GetX, put=PutX)) int x[];

The above statement indicates that x[] can be used with one or more array indices. In this case:

```
i=p->x[a][b]
```

will be turned into:

```
i=p->GetX(a, b),
```

and

```
p->x[a][b] = i
```

will be turned into

```
p->PutX(a, b, i);
```

3.1.3.2.45 __declspec(selectany)

Category

Modifiers, Keyword extensions, Storage class specifiers

Syntax

```
__declspec( selectany ) declarator
```

A global data item can normally be initialized only once in an application or library. This attribute can be used in initializing global data defined by headers, when the same header appears in more than one source file.

Note This attribute can only be applied to the actual initialization of global data items that are externally visible.

Example

This code shows how to use the **selectany** attribute:

```
//Correct - x1 is initialized and externally visible
__declspec(selectany) int x1=1;
//Incorrect - const is by default static in C++, so
//x2 is not visible externally (This is OK in C, since
//const is not by default static in C)
const __declspec(selectany) int x2 =2;
//Correct - x3 is extern const, so externally visible
extern const __declspec(selectany) int x3=3;
//Correct - x4 is extern const, so it is externally visible
extern const int x4;
const __declspec(selectany) int x4=4;
//Incorrect - __declspec(selectany) is applied to the uninitialized //declaration of x5 extern __declspec(selectany) int x5;
```

3.1.3.2.46 __declspec(thread)

Category

Modifiers, Keyword extensions, Storage class specifiers

Syntax

```
__declspec( thread ) declarator
```

Thread Local Storage (TLS) is the method by which each thread in a given multithreaded process allocates storage for thread-specific data.

The **thread** extended storage-class modifier is used to declare a thread local variable. The **thread** attribute must be used with the **__declspec** keyword.

3.1.3.2.47 __declspec(uuid(“ComObjectGUID”))

Category

Modifiers, Keyword extensions, Storage class specifiers

Syntax

```
__declspec( uuid(“ComObjectGUID”) ) declarator
```

The compiler attaches a GUID to a class or structure declared or defined (full COM object definitions only) with the **uuid** attribute. The **uuid** attribute takes a string as its argument. This string names a GUID in normal registry format with or without the **{ }** delimiters. For example:

```
struct __declspec(uuid("00000000-0000-0000-c000-000000000046")) IUnknown;
struct __declspec(uuid("{00020400-0000-0000-c000-000000000046}")) IDispatch;
```

This attribute can be applied in a redeclaration. This allows the system headers to supply the definitions of interfaces such as

IUnknown, and the redeclaration in some other header (such as COMDEF.H) to supply the GUID.

The keyword __uuidof can be applied to retrieve the constant GUID attached to a user-defined type.

3.1.3.2.48 decltype

Category

Type specifiers

Syntax

```
decltype ( expression )
```

Description

Use the **decltype** type specifier to obtain the type specifier of an expression.

decltype may be applied to expressions that are identifiers, class members and function names or calls.

3.1.3.2.49 default

Category

Statements

Syntax

```
switch ( <switch variable> ){casebreakdefault
case <constant expression> : <statement>; [break;]
    .
    .
    .
default : <statement>;
}
```

Description

Use the default statement in switch statement blocks.

- If a case match is not found and the **default** statement is found within the switch statement, the execution continues at this point.
- If no default is defined in the **switch** statement, control passes to the next statement that follows the switch statement block.

Example

This example illustrates the use of keywords **break**, **case**, **default**, **return**, and **switch**.

```
#include <iostream>

using namespace std;

int main(int argc, char* argv[])
{
  char ch;

  cout << "PRESS a, b, OR c. ANY OTHER CHOICE WILL TERMINATE THIS PROGRAM." << endl;
  for ( /* FOREVER */; cin >> ch; )
    switch (ch)
    {
      case 'a' :    /* THE CHOICE OF a HAS ITS OWN ACTION. */
        cout << endl << "Option a was selected." << endl;
        break;
      case 'b' :    /* BOTH b AND c GET THE SAME RESULTS. */
```

```
        case 'c' :
          cout << endl << "Option b or c was selected." << endl;
          break;
        default :
          cout << endl << "NOT A VALID CHOICE!  Bye ..." << endl;
          return(-1);
      }
}
```

See Also

break (see page 534)

case (see page 535)

switch (see page 567)

3.1.3.2.50 delete

Category

Operators, C++-Specific Keywords

Syntax

```
void operator delete(void *ptr) throw();
void operator delete(void *ptr, const std::nothrow_t&) throw();
void operator delete[](void *ptr) throw();
void operator delete[](void *ptr, const std::nothrow_t &) throw();
void operator delete(void *ptr, void *) throw();   // Placement form
void operator delete[](void *ptr, void *) throw(); // Placement form
```

Description

The **delete** operator deallocates a memory block allocated by a previous call to new. It is similar but superior to the standard library function free.

You should use the **delete** operator to remove all memory that has been allocated by the **new** operator. Failure to free memory can result in memory leaks.

The default placement forms of **operator delete** are reserved and cannot be redefined. The default placement **delete** operator performs no action (since no memory was allocated by the default placement **new** operator). If you overload the placement version of operator new, it is a good idea (though not strictly required) to provide the overload the placement delete operator with the corresponding signature.

See Also

Overloading The Operator delete (see page 436)

The Delete Operator With Arrays (see page 437)

3.1.3.2.51 do

Category

Statements

Syntax

```
do <statement> while ( <condition> );
```

Description

The **do** statement executes until the condition becomes **false**.

<statement> is executed repeatedly as long as the value of <condition> remains **true**.

Since the conditon tests after each the loop executes the <statement>, the loop will execute at least once.

See Also

while (see page 574)

3.1.3.2.52 double

Category

Type specifiers

Syntax

```
[long] double <identifier>
```

Description

Use the **double** type specifier to define an identifier to be a floating-point data type. The optional modifier **long** extends the accuracy of the floating-point value.

If you use the **double** keyword, the floating-point math package will automatically be linked into your program.

See Also

float (see page 552)

long (see page 555)

3.1.3.2.53 dynamic_cast (typecast Operator)

Category

C++-Specific Keywords

Description

In the expression, dynamic_cast< T > (ptr), T must be a pointer or a reference to a defined class type or **void***. The argument ptr must be an expression that resolves to a pointer or reference.

If T is void* then ptr must also be a pointer. In this case, the resulting pointer can access any element of the class that is the most derived element in the hierarchy. Such a class cannot be a base for any other class.

Conversions from a derived class to a base class, or from one derived class to another, are as follows: if T is a pointer and ptr is a pointer to a non-base class that is an element of a class hierarchy, the result is a pointer to the unique subclass. References are treated similarly. If T is a reference and ptr is a reference to a non-base class, the result is a reference to the unique subclass.

A conversion from a base class to a derived class can be performed only if the base is a polymorphic type.

The conversion to a base class is resolved at compile time. A conversion from a base class to a derived class, or a conversion across a hierarchy is resolved at runtime.

If successful, dynamic_cast< T > (ptr) converts ptr to the desired type. If a pointer cast fails, the returned pointer is valued 0. If a cast to a reference type fails, the Bad_cast exception is thrown.

Note: Runtime type identification (RTTI) is required for dynamic_cast

.

See Also

Const_cast (typecast Operator) (see page 539)

Reinterpret_cast (typecast Operator) (see page 561)

__rtti (see page 528)

static_cast (typecast Operator) (see page 565)

3.1.3.2.54 enum

Category

Type specifiers

Syntax

```
enum [<type_tag>] {<constant_name> [= <value>], ...} [var_list];
```

- <type_tag> is an optional type tag that names the set.
- <constant_name> is the name of a constant that can optionally be assigned the value of <value>. These are also called enumeration constants.
- <value> must be an integer. If <value> is missing, it is assumed to be: <prev> + 1 where <prev> is the value of the previous integer constant in the list. For the first integer constant in the list, the default value is 0.
- <var_list> is an optional variable list that assigns variables to the enum type.

Description

Use the **enum** keyword to define a set of constants of type **int**, called an enumeration data type.

An enumeration data type provides mnemonic identifiers for a set of integer values. Use the **-b** flag to toggle the Treat Enums As Ints option. .Enums are always interpreted as **int**s if the range of values permits this, but if they are not **int**s the value gets promoted to an **int** in expressions. Depending on the values of the enumerators, identifiers in an enumerator list are implicitly of type **signed char**, **unsigned char**, **short**, **unsigned short**, **int**, or **unsigned int**.

In C, an enumerated variable can be assigned any value of type int--no type checking beyond that is enforced. In C++, an enumerated variable can be assigned only one of its enumerators.

In C++, you can omit the **enum** keyword if <tag_type> is not the name of anything else in the same scope. You can also omit <tag_type> if no further variables of this **enum** type are required.

In the absence of a <value> the first enumerator is assigned the value of zero. Any subsequent names without initializers will then increase by one. <value> can be any expression yielding a positive or negative integer value (after possible integer promotions). These values are usually unique, but duplicates are legal.

Enumeration tags share the same name space as structure and union tags. Enumerators share the same name space as ordinary variable identifiers.

In C++, enumerators declared within a class are in the scope of that class.

3.1.3.2.55 explicit

Category

C++-Specific Keywords

Syntax

```
explicit <single-parameter constructor declaration>
```

Description

Normally, a class with a single-parameter constructor can be assigned a value that matches the constructor type. This value is automatically (implicitly) converted into an object of the class type to which it is being assigned. You can prevent this kind of implicit conversion from occurring by declaring the constructor of the class with the **explicit** keyword. Then all objects of that class must be assigned values that are of the class type; all other assignments result in a compiler error.

Objects of the following class can be assigned values that match the constructor type or the class type:

```
class X {
public:
X(int);
X(const char*, int = 0);
};
```

Then, the following assignment statements are legal.

```
void f(X arg) {
X a = 1;
X B = "Jessie";
a = 2;
}
```

However, objects of the following class can be assigned values that match the class type only:

```
class X {
public:
explicit X(int);
explicit X(const char*, int = 0);
};
```

The **explicit** constructors then require the values in the following assignment statements to be converted to the class type to which they are being assigned.

```
void f(X arg) {
X a = X(1);
X b = X("Jessie",0);
a = X(2);
}
```

3.1.3.2.56 export

Category

Unimplemented

Syntax

```
export template < template-parameter-list > declaration
```

Description

The **export** keyword is reserved for future implementation, but has no effect in this release.

See Also

_export (see page 530)

3.1.3.2.57 extern

Category

Storage class specifiers

Syntax

```
extern <data definition> ;
```

```
[extern] <function prototype> ;
```

Description

Use the **extern** modifier to indicate that the actual storage and initial value of a variable, or body of a function, is defined in a separate source code module. Functions declared with extern are visible throughout all source files in a program, unless you redefine the function as static.

The keyword **extern** is optional for a function prototype.

Use extern "C" to prevent function names from being mangled in C++ programs.

Also, **extern** templates allow you to define templates that are not instantiated in a translation unit. Using **extern** templates thus reduces both compilation time and the size of the compiled module. The extern template (see page 494) feature is part of the new C++0x standard.

3.1.3.2.58 final

Category

Attributes, Keyword extensions

Syntax

```
return-type function-name [[final]]
```

Description

The **final** attribute prevents a class or function from being further inherited. You can add the **final** attribute to a class definition or to a virtual member function declaration inside a class definition. If the attribute is specified for a class definition, it is equivalent to being specified for each virtual member function of that class, including inherited member functions.

See Also

Attributes noreturn and final (see page 492)

3.1.3.2.59 __finally

Category

Statements, Keyword extensions

Syntax

```
__finally {compound-statement}
```

Description

The **__finally** keyword specifies actions that should be taken regardless of how the flow within the preceding __try exits.

The following is the code fragment shows how to use the **try/__finally** construct:

```
#include <stdio.h>#include <string.h>#include <windows.h>class
Exception{public:Exception(char* s = "Unknown"){what = strdup(s);      }Exception(const
Exception& e ){what = strdup(e.what); } ~Exception()                    {free(what);         }
char* msg() const             {return what;           }private:char* what;};int main(){float
e, f, g;try  {try    {f = 1.0;g = 0.0;try      {puts("Another exception:");e = f / g;
}__except(EXCEPTION_EXECUTE_HANDLER)      {puts("Caught a C-based
exception.");throw(Exception("Hardware error: Divide by 0"));      }    }catch(const
Exception& e)    {printf("Caught C++ Exception: %s :\n", e.msg());    }  }__finally
{puts("C++ allows __finally too!");  }return e;}
#include <string.h>
#include <windows.h>
```

```
class Exception
{
public:
Exception(char* s = "Unknown"){what = strdup(s);      }
Exception(const Exception& e ){what = strdup(e.what); }
 ~Exception()                    {free(what);         }
  char* msg() const              {return what;          }
private:
char* what;
};
int main()
{
float e, f, g;
try
  {
try
    {
f = 1.0;
g = 0.0;
try
      {
puts("Another exception:");
e = f / g;
      }
__except(EXCEPTION_EXECUTE_HANDLER)
      {
puts("Caught a C-based exception.");
throw(Exception("Hardware error: Divide by 0"));
      }
    }
catch(const Exception& e)
    {
printf("Caught C++ Exception: %s :\n", e.msg());
    }
  }
__finally
  {
puts("C++ allows __finally too!");
  }
return e;
}
#include <iostream>#include <stdexcept>using namespace std;class MyException : public
exception {public:virtual const char *what() const throw() {return("MyException
occurred.");}};// Give me any integer...void myFunc(int a){ MyException e;   // ...but not
that one.   if(a == 0)     throw(e);}void main(){   int g;   // Note __finally must be in its
own try block (with no preceding catch).   try {     try {       g = 0;       myFunc(g);
}     catch(MyException &e) {       cout << "Exception: " << e.what() << endl;     }   }
__finally {       cout << "Finally block reached." << endl;   }
#include <stdexcept>
using namespace std;
class MyException : public exception {
public:
virtual const char *what() const throw() {
return("MyException occurred.");
}
};
// Give me any integer...
void myFunc(int a)
{
 MyException e;
   // ...but not that one.
   if(a == 0)
     throw(e);
}
void main()
{
```

```
    int g;
    // Note __finally must be in its own try block (with no preceding catch).
    try {
      try {
        g = 0;
        myFunc(g);
      }
      catch(MyException &e) {
        cout << "Exception: " << e.what() << endl;
      }
    }
    __finally {
        cout << "Finally block reached." << endl;
    }
}
```

Running the above program results in the following:

```
Another exception:Caught a C-based exception.Caught C++ exception[Hardware error: Divide by
0]C++ allows __finally too!Exception: MyException occurred.Finally block reached.
Caught a C-based exception.Caught C++ exception[Hardware error: Divide by 0]C++ allows
__finally too!Exception: MyException occurred.Finally block reached.
```

3.1.3.2.60 float

Category

Type specifiers

Syntax

```
float <identifier>
```

Description

Use the **float** type specifier to define an identifier to be a floating-point data type.

Type	Length	Range
float	32 bits	3.4 * (10**-38) to 3.4 * (10**+38)

The floating-point math package will be automatically linked into your program if you use floating-point values or operators.

See Also

double (see page 547)

3.1.3.2.61 for

Category

Statements

Syntax

```
for ( [<initialization>] ; [<condition>] ; [<increment>] )  <statement>
```

Description

The **for** statement implements an iterative loop.

<condition> is checked before the first entry into the block.

<statement> is executed repeatedly UNTIL the value of <condition> is false.

- Before the first iteration of the loop, <initialization> initializes variables for the loop.
- After each iteration of the loop, <increments> increments a loop counter. Consequently, j++ is functionally the same as ++j.

In C++, <initialization> can be an expression or a declaration.

The scope of any identifier declared within the **for** loop extends to the end of the control statement only.

A variable defined in the **for**-initialization expression is in scope only within the **for**-block. See the description of the -Vd option.

All the expressions are optional. If <condition> is left out, it is assumed to be always true.

3.1.3.2.62 friend

Category

C++-Specific Keywords

Syntax

```
friend <identifier>;
```

Description

Use **friend** to declare a function or class with full access rights to the private and protected members of the class, without being a member of that class. The outside class has fill access to the class that declares that outside class a friend.

In all other respects, the **friend** is a normal function in terms of scope, declarations, and definitions.

3.1.3.2.63 goto

Category

Statements

Syntax

```
goto <identifier> ;
```

Description

Use the **goto** statement to transfer control to the location of a local label specified by <identifier>.

Labels are always terminated by a colon.

3.1.3.2.64 if, else

Category

Operators

C++ Syntax

```
if ( <condition1> )  <statement1>
if ( <condition1> )  <statement1>;
 else  <statement2>;
if ( <condition1> )  <statement1>;
 else if ( <condition2> )  <statement2>;
 else  <statement3>;
if ( <condition1> )
{
  if ( <condition2> ) {
  <statement1>
  <statement2>
```

```
  }
  else <statement3>
}
else
  <statement4>
```

Description

Use **if** to implement a conditional statement.

You can declare variables in the condition expression. For example,

```
if (int val = func(arg))
```

is valid syntax. The variable val is in scope for the **if** statement and extends to an **else** block when it exists.

The condition statement must convert to a **bool** type. Otherwise, the condition is ill-formed.

When <condition> evaluates to **true**, <statement1> executes.

If <condition> is **false**, <statement2> executes.

The **else** keyword is optional, but no statements can come between an **if** statement and an **else**.

The #if and #else preprocessor statements (directives) look similar to the **if** and **else** statements, but have very different effects. They control which source file lines are compiled and which are ignored.

3.1.3.2.65 import, _import, __import

Category

Modifiers, Keyword extensions

Form 1

```
class _import <class name>
class __import <class name>
```

Form 2

```
return_type _import <function name>
return_type __import <function name>
```

Form 3

```
data_type _import <data name>
data_type __import <data name>
```

Description

This keyword can be used as a class, function, or data modifier.

3.1.3.2.66 inline

Category

C++-Specific Keywords

Syntax

```
inline <datatype> <class>_<function> (<parameters>) { <statements>; }
```

Description

Use the **inline** keyword to declare or define C++ inline functions.

Inline functions are best reserved for small, frequently used functions.

3.1.3.2.67 int

Category

Type specifiers

Syntax

```
[signed|unsigned] int <identifier> ;
```

Description

Use the **int** type specifier to define an integer data type.

Variables of type **int** can be signed (default) or unsigned.

3.1.3.2.68 long

Category

Type specifiers

Syntax

```
long [int] <identifier> ;
[long] double <identifier> ;
```

Description

When used to modify a **double**, it defines a floating-point data type with 80 bits of precision instead of 64.

The floating-point math package will be automatically linked with your program if you use floating-point values or operators.

3.1.3.2.69 mutable

Category

C++-Specific Keywords, Storage class specifiers

Syntax

```
mutable <variable name>;
```

Description

Use the **mutable** specifier to make a variable modifiable even though it is in a **const**-qualified expression.

Using the mutable Keyword

Only class data members can be declared mutable. The **mutable** keyword cannot be used on **static** or **const** names. The purpose of **mutable** is to specify which data members can be modified by **const** member functions. Normally, a **const** member function cannot modify data members.

See Also

const (see page 538)

3.1.3.2.70 namespace

Category

C++-Specific Keywords

Description

Most real-world applications consist of more than one source file. The files can be authored and maintained by more than one developer. Eventually, the separate files are organized and linked to produce the final application. Traditionally, the file organization requires that all names that aren't encapsulated within a defined namespace (such as function or class body, or translation unit) must share the same global namespace. Therefore, multiple definitions of names discovered while linking separate modules require some way to distinguish each name. The solution to the problem of name clashes in the global scope is provided by the C++ namespace mechanism.

The namespace mechanism allows an application to be partitioned into a number of subsystems. Each subsystem can define and operate within its own scope. Each developer is free to introduce whatever identifiers are convenient within a subsystem without worrying about whether such identifiers are being used by someone else. The subsystem scope is known throughout the application by a unique identifier.

It only takes two steps to use C++ namespaces. The first is to uniquely identify a namespace with the keyword **namespace**. The second is to access the elements of an identified namespace by applying the **using** keyword.

3.1.3.2.71 new

Category

Operators, C++-Specific Keywords

Syntax

```
void *operator new(std::size_t size) throw(std::bad_alloc);
void *operator new(std::size_t size, const std::nothrow_t &) throw();
void *operator new[](std::size_t size) throw(std::bad_alloc);
void *operator new[](std::size_t size, const std::nothrow_t &) throw();
void *operator new(std::size_t size, void *ptr) throw();    // Placement form
void *operator new[](std::size_t size, void *ptr) throw();  // Placement form
```

Description

The **new** operators offer dynamic storage allocation, similar but superior to the standard library function malloc. These allocation functions attempt to allocate size bytes of storage. If successful, **new** returns a pointer to the allocated memory. If the allocation fails, the **new** operator will call the new_handler function. The default behavior of new_handler is to throw an exception of type bad_alloc. If you do not want an exception to be thrown, use the nothrow version of **operator new**. The nothrow versions return a null pointer result on failure, instead of throwing an exception.

The default placement forms of **operator new** are reserved and cannot be redefined. You can, however, overload the placement form with a different signature (i.e. one having a different number, or different type of arguments). The default placement forms accept a pointer of type void, and perform no action other than to return that pointer, unchanged. This can be useful when you want to allocate an object at a known address. Using the placement form of **new** can be tricky, as you must remember to explicitly call the destructor for your object, and then free the pre-allocated memory buffer. Do not call the **delete** operator on an object allocated with the placement **new** operator.

A request for non-array allocation uses the appropriate **operator new()** function. Any request for array allocation will call the appropriate **operator new[]()** function. Remember to use the array form of **operator delete[]()**, when deallocating an array created with **operator new[]()**.

Note: Arrays of classes require that a default constructor be defined in the class.

A request for allocation of 0 bytes returns a non-null pointer. Repeated requests for zero-size allocations return distinct, non-null pointers.

Example of Operator new with Nothrow

```
#include <new>
int main(int argc, char* argv[])
{
   int *pn;
        // nothrow version returns null pointer rather than throwing a
        // bad_alloc exception.
        pn = new(nothrow) int[5000000];
        if(pn != NULL) {
          // Allocation succeded.
        }
        return 0;
}
```

Delete (see page 546)

The Operator new With Arrays (see page 437)

Operator new (see page 437)

Operator new Placement Syntax (see page 436)

Handling Errors For The New Operator (see page 435)

3.1.3.2.72 noreturn

Category

Attributes, Keyword extensions

Syntax

```
void function-name [[noreturn]]
```

Description

Use the **noreturn** modifier to declare functions that have no return value.

See Also

Attributes noreturn and final (see page 492)

3.1.3.2.73 not, !

Category

Alternative Representations of Operators and Tokens, Operators

Syntax

Description

The **not** operator is an alternative representation of the **!**operator (logical negation).

not returns *true* if its operand is *false*, and *false* if its operand is *true*t.

If an integer is 1, the expression of !1 indicates that the number is other than 1 So that is a true statement. **not** can also be used

for strings as well. The expression !Smith indicates that the person's name is other than Smith.. **not** inverts the bits of the expression.

In order to use the **not** operator, you need to check the **Enable new operator names** option (the **-VM** compiler switch, available on the **Compatibility** page of the **Project**▸**Options** dialog box).

3.1.3.2.74 not_eq, !=

Category

Alternative Representations of Operators and Tokens, Operators

Syntax

Description

The **not_eq** operator is an alternative representation of **!=** (bitwise inequality). It tests for logical inequivalence.

not_eq compares two expressions to determine whether or not they are the same.

Therefore, 7 != 8 returns true, while 7 != 7 returns false. The same is true for any expression such as Smith != Smith. which returns false.

In order to use the **not_eq** operator, you need to check the **Enable new operator names** option (the **-VM** compiler switch, available on the **Compatibility** page of the **Project**▸**Options** dialog box).

3.1.3.2.75 nullptr

Category

Reserved Words

Syntax

```
nullptr
```

Description

Reserved for future use. **nullptr** is a literal that can be assigned to any pointer to indicate the pointer doesn't point to anything.

Warning: C++Builder does not implement nullptr

but does treat it as a keyword when the -Ax compiler flag is set. Do not use **nullptr** as an identifier.

3.1.3.2.76 operator

Category

Operators, C++-Specific Keywords

Syntax

```
operator <operator symbol>( <parameters> )
{
<statements>;
}
```

Description

Use the **operator** keyword to define a new (overloaded) action of the given operator. When the operator is overloaded as a member function, only one argument is allowed, as *this is implicitly the first argument.

When you overload an operator as a friend, you can specify two arguments.

See Also

class (see page 537)

3.1.3.2.77 or, ||

Category

Alternative Representations of Operators and Tokens, Operators

Syntax

Description

The **or** operator is an alternative representation of the **||** operator (logical OR).

Only two statements can be evaluated at a time.

or returns true if two values are different, such as 2 or 6.

or returns false if both values are the same, such as 10 and 10.

In order to use the **or** operator, you need to check the **Enable new operator names** option (the **-VM** compiler switch, available on the **Compatibility** page of the **Project**▸**Options** dialog box).

3.1.3.2.78 or_eq, |=

Category

Alternative Representations of Operators and Tokens, Operators

Syntax

Description

The **or_eq** operator is an alternative representation of **!=**(bitwise inclusive OR).

or_eq tests for logical equivalence or bitwise equality.

or_eq operates on two values. When the first value or the second value is 1, true is returned. When the values are 0, false is returned.

In order to use the **not_eq** operator, you need to check the **Enable new operator names** option (the **-VM** compiler switch, available on the **Compatibility** page of the **Project**▸**Options** dialog box).

3.1.3.2.79 pascal, _pascal, __pascal

Category

Modifiers, Keyword extensions

Syntax

```
pascal <data-definition/function-definition> ;
_pascal <data-definition/function-definition> ;
__pascal <data-definition/function-definition> ;
```

Description

Use the **pascal**, **_pascal**, and **__pascal** keywords to declare a variable or a function using a Pascal-style naming convention

(the name is in uppercase).

In addition, **pascal** declares Delphi language-style parameter-passing conventions when applied to a function header (parameters pushed left to right; the called function cleans up the stack).

In C++ programs, functions declared with the **pascal** modifier are still mangled.

3.1.3.2.80 private

Category

C++-Specific Keywords

Syntax

```
private: <declarations>
```

Description

Access to **private** class members is restricted to member functions within the class, and to **friend** classes.

Class members are **private** by default.

Structure (**struct**) and **union** members are **public** by default. You can override the default access specifier for structures, but not for unions.

Friend declarations can be placed anywhere in the class declaration; friends are not affected by access control specifiers.

See Also

class (see page 537)

friend (see page 553)

Protected (see page 560)

3.1.3.2.81 protected

Category

C++-Specific Keywords

Syntax

```
protected: <declarations>
```

Description

Access to **protected** class members is restricted to member functions within the class, member functions of derived classes, and to **friend** classes.

Structure (**struct**) and **union** members are **public** by default. You can override the default access specifier for structures, but not for unions.

Friend declarations can be placed anywhere in the class declaration; friends are not affected by access control specifiers.

See Also

class (see page 537)

friend (see page 553)

Private (see page 560)

3.1.3.2.82 public

Category

C++-Specific Keywords

Syntax

```
public: <declarations>
```

Description

A **public** class member can be accessed by any function.

Members of a struct or union are **public** by default.

You can override the default access specifier for structures, but not for unions.

Friend declarations can be placed anywhere in the class declaration; friends are not affected by access control specifiers.

See Also

class (see page 537)

friend (see page 553)

Private (see page 560)

Protected (see page 560)

__published (see page 528)

struct (see page 566)

3.1.3.2.83 register

Category

Storage class specifiers

Syntax

```
register <data definition> ;
```

Description

Use the register storage class specifier to store the variable being declared in a CPU register (if possible), to optimize access and reduce code.

Note: The compiler can ignore requests for register allocation. Register allocation is based on the compiler's analysis of how a variable is used.

3.1.3.2.84 reinterpret_cast (typecast Operator)

Category

C++-Specific Keywords

Syntax

```
reinterpret_cast< T > (arg)
```

Description

In the statement, reinterpret_cast< T > (arg), T must be a pointer, reference, arithmetic type, pointer to function, or pointer to member.

A pointer can be explicitly converted to an integral type.

An integral arg can be converted to a pointer. Converting a pointer to an integral type and back to the same pointer type results in the original value.

A yet undefined class can be used in a pointer or reference conversion.

A pointer to a function can be explicitly converted to a pointer to an object type provided the object pointer type has enough bits to hold the function pointer. A pointer to an object type can be explicitly converted to a pointer to a function only if the function pointer type is large enough to hold the object pointer.

See Also

Const_cast (typecast Operator) (see page 539)

Dynamic_cast (typecast Operator) (see page 547)

3.1.3.2.85 return

Category

Statements

Syntax

```
return [ <expression> ] ;
```

Description

Use the **return** statement to exit from the current function back to the calling routine, optionally returning a value.

Example

This example illustrates the use of keywords **break**, **case**, **default**, **return**, and **switch**.

```
#include <iostream>

using namespace std;

int main(int argc, char* argv[])
int main(int argc, char* argv[])
{
  char ch;

  cout << "PRESS a, b, OR c. ANY OTHER CHOICE WILL TERMINATE THIS PROGRAM." << endl;
  for ( /* FOREVER */; cin >> ch; )
  switch (ch)
  {
    case 'a' :    /* THE CHOICE OF a HAS ITS OWN ACTION. */
      cout << endl << "Option a was selected." << endl;
      break;
    case 'b' :    /* BOTH b AND c GET THE SAME RESULTS. */
    case 'c' :
      cout << endl << "Option b or c was selected." << endl;
      break;
    default :
      cout << endl << "NOT A VALID CHOICE!  Bye ..." << endl;
      return(-1);
    }
}
```

3.1.3.2.86 short

Category

Type specifiers

Syntax

```
short int <variable> ;
```

Description

Use the short type modifier when you want a variable smaller than an int. This modifier can be applied to the base type int.

When the base type is omitted from a declaration, int is assumed.

See Also

long (see page 555)

signed (see page 563)

3.1.3.2.87 signed

Category

Type specifiers

Syntax

```
signed <type> <variable> ;
```

Description

Use the signed type modifier when the variable value can be either positive or negative. The signed modifier can be applied to base types **int**, **char**, **long**, **short**, and **__int64**.

When the base type is omitted from a declaration, **int** is assumed.

See Also

char (see page 536)

int (see page 555)

long (see page 555)

short (see page 563)

unsigned (see page 571)

3.1.3.2.88 sizeof

Category

Operators

Description

The **sizeof** operator has two distinct uses:

sizeof unary-expression

sizeof (type-name)

The result in both cases is an integer constant that gives the size in bytes of how much memory space is used by the operand (determined by its type, with some exceptions). The amount of space that is reserved for each type depends on the machine.

In the first use, the type of the operand expression is determined without evaluating the expression (and therefore without side effects). When the operand is of type **char** (**signed** or **unsigned**), **sizeof** gives the result 1. When the operand is a non-parameter of array type, the result is the total number of bytes in the array (in other words, an array name is not converted to a pointer type). The number of elements in an array equals sizeof array/ sizeof array[0] .

If the operand is a parameter declared as array type or function type, **sizeof** gives the size of the pointer. When applied to structures and unions, **sizeof** gives the total number of bytes, including any padding.

You cannot use **sizeof** with expressions of function type, incomplete types, parenthesized names of such types, or with an lvalue that designates a bit field object.

The integer type of the result of **sizeof** is size_t.

You can use **sizeof** in preprocessor directives; this is specific to CodeGear C++.

In C++, sizeof(classtype), where classtype is derived from some base class, returns the size of the object (remember, this includes the size of the base class).

Example

```
/*  USE THE sizeof OPERATOR TO GET SIZES OF DIFFERENT DATA TYPES. */
#include <stdio.h>
struct st {
char *name;
int age;
double height;
};
struct st St_Array[]= {  /* AN ARRAY OF structs */
{ "Jr.",     4,  34.20 },  /* St_Array[0] */
{ "Suzie",  23,  69.75 },  /* St_Array[1] */
};
int main()
{
long double LD_Array[] = { 1.3, 501.09, 0.0007, 90.1, 17.08 };
printf("\nNumber of elements in LD_Array = %d",
sizeof(LD_Array) / sizeof(LD_Array[0]));
/****  THE NUMBER OF ELEMENTS IN THE St_Array. ****/
printf("\nSt_Array has %d elements",
sizeof(St_Array)/sizeof(St_Array[0]));
/****  THE NUMBER OF BYTES IN EACH St_Array ELEMENT.  ****/
printf("\nSt_Array[0] = %d", sizeof(St_Array[0]));
/****  THE TOTAL NUMBER OF BYTES IN St_Array.  ****/
printf("\nSt_Array=%d", sizeof(St_Array));
return 0;
}
```

Output

```
Number of elements in LD_Array = 5
St_Array has 2 elements
St_Array[0] = 16
St_Array= 32
```

3.1.3.2.89 static

Category

Storage class specifiers

Syntax

```
static <data definition> ;static
static <function name> <function definition> ;
```

Description

Use the **static** storage class specifier with a local variable to preserve the last value between successive calls to that function. A **static** variable acts like a local variable but has the lifetime of an external variable.

In a class, data and member functions can be declared **static**. Only one copy of the **static** data exists for all objects of the class.

A **static** member function of a global class has external linkage. A member of a local class has no linkage. A **static** member function is associated only with the class in which it is declared. Therefore, such member functions cannot be **virtual**.

Static member functions can only call other **static** member functions and only have access to **static** data. Such member functions do not have a **this** pointer.

See Also

Static Members (see page 394)

3.1.3.2.90 static_assert

Category

Statements, C++-Specific Keywords

Syntax

```
static_assert (constant-expression, error-message);
```

Description

The **static_assert** keyword is used to test assertions at compile-time, rather than at preprocessor or run-time.

3.1.3.2.91 static_cast (typecast Operator)

Category

C++-Specific Keywords

Syntax

```
static_cast< T > (arg)
```

Description

In the statement, static_cast< T > (arg), T must be a pointer, reference, arithmetic type, or enum type. Both T and arg must be fully known at compile time.

If a complete type can be converted to another type by some conversion method already provided by the language, then making such a conversion by using **static_cast** achieves exactly the same thing.

Integral types can be converted to **enum** types. A request to convert arg to a value that is not an element of **enum** is undefined.

The null pointer is converted to the null pointer value of the destination type, T.

A pointer to one object type can be converted to a pointer to another object type. Note that merely pointing to similar types can cause access problems if the similar types are not similarly aligned.

You can explicitly convert a pointer to a class X to a pointer to some class Y if X is a base class for Y. A static conversion can be made only under the following conditions:

- if an unambiguous conversion exists from Y to X
- if X is not a virtual base class

An object can be explicitly converted to a reference type X& if a pointer to that object can be explicitly converted to an X*. The result of the conversion is an lvalue. No constructors or conversion functions are called as the result of a cast to a reference.

An object or a value can be converted to a class object only if an appropriate constructor or conversion operator has been declared.

A pointer to a member can be explicitly converted into a different pointer-to-member type only if both types are pointers to members of the same class or pointers to members of two classes, one of which is unambiguously derived from the other.

When T is a reference the result of static_cast< T > (arg) is an lvalue. The result of a pointer or reference cast refers to the original expression.

See Also

Const_cast (typecast Operator) (see page 539)

Dynamic_cast (typecast Operator) (see page 547)

Reinterpret_cast (typecast Operator) (see page 561)

3.1.3.2.92 struct

Category

Type specifiers

Syntax

```
struct [<struct type name>] {
[<type> <variable-name[, variable-name, ...]>] ;
    .
    .
    .
} [<structure variables>] ;
```

Description

Use a **struct** to group variables into a single record.

<struct type name> An optional tag name that refers to the structure type.

<structure variables> The data definitions, also optional.

Though both <struct type name> and <structure variables> are optional, one of the two must appear.

You define elements in the record by naming a <type>, followed by one or more <variable-name> (separated by commas).

Separate different variable types by a semicolon.

Use the **.** operator, or the **->** operator to access elements in a structure.

To declare additional variables of the same type, use the keyword **struct** followed by the <struct type name>, followed by the variable names. In C++ the keyword **struct** can be omitted.

Note: The compiler allows the use of anonymous struct embedded within another structure.

See Also

class (see page 537)

public (see page 561)

union (see page 571)

3.1.3.2.93 switch

Category

Statements

Syntax

```
switch ( <switch variable> ) {casebreakdefault
case <constant expression> : <statement>; [break;]
    .
    .
    .
default : <statement>;
}
```

Description

Use the switch statement to pass control to a case that matches the <switch variable>. At which point the statements following the matching case evaluate.

If no case satisfies the condition the default case evaluates.

To avoid evaluating any other cases and relinquish control from the switch, terminate each case with **break**.

Example

This example illustrates the use of keywords **break**, **case**, **default**, **return**, and **switch**.

```
#include <iostream>

using namespace std;

int main(int argc, char* argv[])
{
  char ch;

  cout << "PRESS a, b, OR c. ANY OTHER CHOICE WILL TERMINATE THIS PROGRAM." << endl;
  for ( /* FOREVER */; cin >> ch; )
    switch (ch)
    {
      case 'a' :    /* THE CHOICE OF a HAS ITS OWN ACTION. */
        cout << endl << "Option a was selected." << endl;
        break;
      case 'b' :    /* BOTH b AND c GET THE SAME RESULTS. */
      case 'c' :
        cout << endl << "Option b or c was selected." << endl;
        break;
      default :
        cout << endl << "NOT A VALID CHOICE!  Bye ..." << endl;
        return(-1);
    }
}
```

See Also

break (see page 534)

case (see page 535)

default (see page 545)

3.1.3.2.94 template

Category

C++-Specific Keywords

Syntax

```
template-declaration:templateclass
   template < template-argument-list > declaration
template-argument-list:
   template-argument
   template-argument-list, template argument
template-argument:
   type-argument
   argument-declaration
type-argument:
   class typename identifier
template-class-name:
   template-name < template-arg-list >
template-arg-list:
   template-arg
   template-arg-list , template-arg
template-arg:
   expression
   type-name
< template-argument-list > declaration
```

Description

Use templates (also called generics or parameterized types) to construct a family of related functions or classes.

3.1.3.2.95 this

Category

C++-Specific Keywords

Example

```
class X {
  int a;
public:
  X (int b) {this -> a = b;}
};
```

Description

In nonstatic member functions, the keyword **this** is a pointer to the object for which the function is called. All calls to nonstatic member functions pass **this** as a hidden argument.

this is a local variable available in the body of any nonstatic member function. Use it implicitly within the function for member references. It does not need to be declared and it is rarely referred to explicitly in a function definition.

For example, in the call x.func(y) , where y is a member of X, the keyword **this** is set to &x and y is set to this->y, which is equivalent to x.y.

Static member functions do not have a **this** pointer because they are called with no particular object in mind. Thus, a static member function cannot access nonstatic members without explicitly specifying an object with . or ->.

See Also

class (see page 537)

3.1.3.2.96 throw

Category

Statements, C++-Specific Keywords

Syntax

```
throw assignment-expression
```

Description

When an exception occurs, the throw expression initializes a temporary object of the type T (to match the type of argument arg) used in throw(T arg). Other copies can be generated as required by the compiler. Consequently, it can be useful to define a copy constructor for the exception object.

See Also

catch (see page 536)

3.1.3.2.97 try

Category

Statements, C++-Specific Keywords

Syntax

```
try compound-statement handler-list
```

Description

The **try** keyword is supported only in C++ programs. Use __try in C programs. C++ also allows __**try**.

A block of code in which an exception can occur must be prefixed by the keyword **try**. Following the try keyword is a block of code enclosed by braces. This indicates that the program is prepared to test for the existence of exceptions. If an exception occurs, the program flow is interrupted. The sequence of steps taken is as follows:

- The program searches for a matching handler
- If a handler is found, the stack is unwound to that point
- Program control is tranferred to the handler

If no handler is found, the program will call the terminate function. If no exceptions are thrown, the program executes in the normal fashion.

See Also

catch (see page 536)

3.1.3.2.98 typedef

Category

Storage class specifiers

Syntax

```
typedef <type definition> <identifier> ;
```

Description

Use the **typedef** keyword to assign the symbol name <identifier> to the data type definition <type definition>.

3.1.3.2.99 typeid

Category

Operators, C++-Specific Keywords

Syntax

```
typeid( expression )
typeid( type-name )
```

Description

You can use **typeid** to get runtime identification of types and expressions. A call to **typeid** returns a reference to an object of type **const** type_info. The returned object represents the type of the **typeid** operand.

If the **typeid** operand is a dereferenced pointer or a reference to a polymorphic type, **typeid** returns the dynamic type of the actual object pointed or referred to. If the operand is non-polymorphic, **typeid** returns an object that represents the static type.

You can use the **typeid** operator with fundamental data types as well as user-defined types.

When the **typeid** operand is a Delphi class object/reference, **typeid** returns the static rather than runtime type.

If the **typeid** operand is a dereferenced NULL pointer, the Bad_typeid exception is thrown.

3.1.3.2.100 typename

Category

C++-Specific Keywords

Syntax 1

```
typename identifier
```

Syntax 2

```
template < typename identifier  > class identifier
```

Description

Use the syntax 1 to reference a type that you have not yet defined. See example 1.

Use syntax 2 in place of the **class** keyword in a template declaration. See example 2.

Note: When using the typename

keyword with templates, the compiler will not always report an error in cases where the ANSI standard requires the typename keyword. The compiler will flag the omission of typename when the compiler is invoked with the **-A** switch. For example, given the following code:

```
#include <stdio.h>
struct A{ typedef int AInt; };
```

Note: The compiler will flag the omission of typename when the compiler is invoked with the -A

switch.

Note: Compile with: bcc32 (no -A switch)

```
bc++bcc32 test.cpp
```

The result is no error. The Compiler should not assume AInt is a **typename**, but it does unless **-A** switch is used

Note: Compile with: bcc32 (-A

switch)

```
bc++bcc32 -A test.cpp
```

The result is:

Error E2089 47071.cpp 7: Identifier 'AInt' cannot have a type qualifier

Error E2303 47071.cpp 7: Type name expected

Error E2139 47071.cpp 7: Declaration missing ;

Both results are as expected.

3.1.3.2.101 union

Category

Type specifiers

Syntax

```
union [<union type name>] {
<type> <variable names> ;
  ...
} [<union variables>] ;
```

Description

Use unions to define variables that share storage space.

The compiler allocates enough storage in a_number to accommodate the largest element in the union.

Unlike a struct, the members of a union occupy the same location in memory. Writing into one overwrites all others.

Use the record selector (.) to access elements of a union .

See Also

class (see page 537)

public (see page 561)

3.1.3.2.102 unsigned

Category

Type specifiers

Syntax

```
unsigned <type> <variable> ;
```

Description

Use the **unsigned** type modifier when variable values will always be positive. The **unsigned** modifer can be applied to base types **int**, **char**, **long, short,** and **__int64**.

When the base type is omitted from a declaration, **int** is assumed.

See Also

char (see page 536)

int (see page 555)

long (see page 555)

short (see page 563)

signed (see page 563)

3.1.3.2.103 using (declaration)

Category

C++-Specific Keywords

Description

You can access namespace members individually with the using-declaration syntax. When you make a using declaration, you add the declared identifier to the local namespace. The grammar is

using-declaration:

using :: unqualified-identifier;

3.1.3.2.104 virtual

Category

C++-Specific Keywords

Syntax

```
virtual class-namevirtual
virtual function-name
```

Description

Use the **virtual** keyword to allow derived classes to provide different versions of a base class function. Once you declare a function as **virtual**, you can redefine it in any derived class, even if the number and type of arguments are the same.

The redefined function overrides the base class function.

3.1.3.2.105 void

Category

Special types

Syntax

```
void identifier
```

Description

void is a special type indicating the absence of any value. Use the **void** keyword as a function return type if the function does not return a value.

```
void hello(char *name)
{
```

```
printf("Hello, %s.",name);
}
```

Use **void** as a function heading if the function does not take any parameters.

```
int init(void)
{
return 1;
}
```

Void Pointers

Generic pointers can also be declared as **void**, meaning that they can point to any type.

void pointers cannot be dereferenced without explicit casting because the compiler cannot determine the size of the pointer object.

3.1.3.2.106 volatile

Category

Modifiers

Syntax

```
volatile <data definition> ;
```

Description

Use the **volatile** modifier to indicate that a background routine, an interrupt routine, or an I/O port can change a variable. Declaring an object to be **volatile** warns the compiler not to make assumptions concerning the value of the object while evaluating expressions in which it occurs because the value could change at any moment. It also prevents the compiler from making the variable a **register** variable.

```
volatile int ticks;
void timer( ) {
ticks++;
}
void wait (int interval) {
ticks = 0;
while (ticks < interval);  // Do nothing
}
```

The routines in this example (assuming timer has been properly associated with a hardware clock interrupt) implement a timed wait of ticks specified by the argument interval. A highly optimizing compiler might not load the value of ticks inside the test of the **while** loop since the loop doesn't change the value of ticks.

Note: C++ extends volatile

to include classes and member functions. If you've declared a **volatile** object, you can use only its **volatile** member functions.

See Also

const (see page 538)

3.1.3.2.107 wchar_t

Category

C++-Specific Keywords, Type specifiers

Syntax

```
wchar_t <identifier>;
```

Description

In C++ programs, **wchar_t** is a fundamental data type that can represent distinct codes for any element of the largest extended character set in any of the supported locales. In CodeGear C++, A **wchar_t** type is the same size, signedness, and alignment requirement as an unsigned short type.

3.1.3.2.108 while

Category

Statements

Syntax

```
while ( <condition> ) <statement>
```

Description

Use the **while** keyword to conditionally iterate a statement.

<statement> executes repeatedly until the value of <condition> is **false**.

The test takes place before <statement> executes. Thus, if <condition> evaluates to **false** on the first pass, the loop does not execute.

3.1.3.2.109 xor, ^

Category

Alternative Representations of Operators and Tokens, Operators

Syntax

Description

The **xor** operator is an alternative representation of the **^** operator (bitwise xor).

It returns a Boolean true result if just one of its operands is true. This is in opposition to an inclusive **or** which denotes that both statements must be integers for a true statement to be returned.

If 2 or 8.25 are stated to be integers, a true statement will be returned even though 8.25 is a decimal.

If Jack and Jill are both stated to be male, a true statement would be returned even though Jill is female.

In order to use the **xor** operator, you need to check the **Enable new operator names** option (the **-VM** compiler switch, available on the **Compatibility** page of the **Project ▸ Options** dialog box).

3.1.3.2.110 __classmethod

Category

Modifiers, Keyword extensions

Syntax

```
virtual __classmethod int <funcdecl> ( int );
        __classmethod virtual int <funcdecl> (int );
```

Description

The __**classmethod** keyword was added to declare class methods in C++. The modifier __**classmethod** indicates that a function may be invoked on a class name--as well as on an instance of that class.

See Also

__classid (see page 523)

Class Methods (see page 406)

3.1.3.2.111 alignas

Category

C++-Specific Keywords

Syntax

```
alignas
```

Description

Reserved for future use.

Warning: C++Builder does not implement alignas

but does treat it as a keyword when the -Ax compiler flag is set.

3.1.3.2.112 and_eq, &=

Category

Alternative Representations of Operators and Tokens, Operators

Syntax

Description

The **and_eq** operator is an alternative representation of the **&=** assignment operator (bitwise AND).

The value of the first operand is added to the value of the second operand, and the result is stored in the first operand.

In order to use the **and_eq** operator, you need to check the **Enable new operator names** option (the **-Vn** compiler switch, available on the **Compatibility** page of the **Project** ▸ **Options** dialog box).

See Also

Assignment Operators (see page 591)

3.1.3.2.113 axiom

Category

Reserved Words

Syntax

```
axiom
```

Description

Reserved for future use.

Warning: C++Builder does not implement axiom

but does treat it as a keyword when the -Ax compiler flag is set.

3.1.3.2.114 concept

Category

Reserved Words

Syntax

```
concept
```

Description

Reserved for future use.

Warning: C++Builder does not implement concept

but does treat it as a keyword when the -Ax compiler flag is set.

3.1.3.2.115 concept_map

Category

Reserved Words

Syntax

```
concept_map
```

Description

Reserved for future use.

Warning: C++Builder does not implement concept_map

but does treat it as a keyword when the -Ax compiler flag is set.

3.1.3.2.116 constexpr

Category

Reserved Words

Syntax

```
constexpr
```

Description

Reserved for future use.

Warning: C++Builder does not implement constexpr

but does treat it as a keyword when the -Ax compiler flag is set.

3.1.3.2.117 late_check

Category

Reserved Words

Syntax

```
late_check
```

Description

Reserved for future use.

Warning: C++Builder does not implement late_check

but does treat it as a keyword when the -Ax compiler flag is set.

3.1.3.2.118 requires

Category

Reserved Words

Syntax

```
requires
```

Description

Reserved for future use.

Warning: C++Builder does not implement requires

but does treat it as a keyword when the -Ax compiler flag is set.

3.1.3.2.119 thread_local

Category

Reserved Words

Syntax

```
thread_local
```

Description

Reserved for future use.

Warning: C++Builder does not implement thread_local

but does treat it as a keyword when the -Ax compiler flag is set.

3.1.3.2.120 xor_eq, ^=

Category

Alternative Representations of Operators and Tokens, Operators

Syntax

Description

The **xor_eq** operator is an alternative representation of the **^=;** operator (bitwise XOR assignment)..

True is returned if one number on the left side of an equation is the same as another number on the right side, such as 10*5!=10*2.

False is returned even if 6*3=9*2.

In order to use the **xor** operator, you need to check the **Enable new operator names** option (the **-VM** compiler switch, available on the **Compatibility** page of the **Project**▶**Options** dialog box).

3.1.3.2.121 _Bool

Category

Reserved Words

Syntax

```
_Bool
```

Description

Reserved for future use.

Warning: C++Builder does not implement _Bool

but does treat it as a keyword when the -An compiler flag is set.

3.1.3.2.122 _Complex

Category

Reserved Words

Syntax

```
_Complex
```

Description

Reserved for future use.

Warning: C++Builder does not implement _Complex

but does treat it as a keyword when the -An compiler flag is set.

3.1.3.2.123 _Imaginary

Category

Reserved Words

Syntax

```
_Imaginary
```

Description

Reserved for future use. **_Imaginary** is a literal that can be assigned to any pointer to indicate the pointer doesn't point to anything.

Warning: C++Builder does not implement _Imaginary

but does treat it as a keyword when the -An compiler flag is set. Do not use **_Imaginary** as an identifier.

3.1.3.2.124 restrict

Category

Reserved Words

Syntax

```
restrict
```

Description

Reserved for future use.

Warning: C++Builder does not implement restrict

but does treat it as a keyword when the -An compiler flag is set.

3.1.3.3 Keywords, By Category

This section contains Keywords, By Category topics.

Topics

Name	Description
Alternative Representations of Tokens (see page 579)	This section contains topics about alternative representations of C++ tokens.

3.1.3.3.1 Alternative Representations of Tokens

This section contains topics about alternative representations of C++ tokens.

Keyword Topics

The following table summarizes the alternative representation keywords and the token that each keyword represents.

Keyword / Alternative Representation	Token Represented	Definition
and (see page 531)	&&	logical AND
and_eq (see page 575)	&=	assignment by bitwise AND
bitand (see page 533)	&	bitwise AND
bitor (see page 533)	|	bitwise OR
compl (see page 538)	~	bitwise NOT (bitwise one's complement)
not (see page 557)	!	logical negation
not_eq (see page 558)	!=	bitwise inequality

or (see page 559)	||	logical OR
or_eq (see page 559)	|=	bitwise inclusive OR
xor (see page 574)	^	bitwise exclusive OR
xor_eq (see page 577)	^=	bitwise XOR assignment

3.1.3.3.11 Type Specifiers (C++)

This section contains C++ Type Specifier keyword topics.

Keyword Topics

char (see page 536)

case (see page 535)

char16_t (see page 537)

char32_t (see page 537)

class (see page 537)

decltype (see page 545)

double (see page 547)

enum (see page 548)

float (see page 552)

int (see page 555)

long (see page 555)

short (see page 563)

signed (see page 563)

struct (see page 566)

union (see page 571)

unsigned (see page 571)

wchar_t (see page 573)

3.1.3.4 Language Structure

The topics in this section provide a formal definition of C++ language and its implementation in the CodeGear C++ compiler. They describe the legal ways in which tokens can be grouped together to form expressions, statements, and other significant units.

Topics

Name	Description
Binary Operators (see page 587)	This section contains Binary Operator topics.
Declarations (see page 593)	This section briefly reviews concepts related to declarations: objects, storage classes, types, scope, visibility, duration, and linkage. A general knowledge of these is essential before tackling the full declaration syntax. Scope, visibility, duration, and linkage determine those portions of a program that can make legal references to an identifier in order to access its object.
Declaration Syntax (see page 600)	All six interrelated attributes (storage classes, types, scope, visibility, duration, and linkage) are determined in diverse ways by declarations. Declarations can be defining declarations (also known as definitions) or referencing declarations (sometimes known as nondefining declarations). A defining declaration, as the name implies, performs both the duties of declaring and defining; the nondefining declarations require a definition to be added somewhere in the program. A referencing declaration introduces one or more identifier names into a program. A definition actually allocates memory to an object and associates an identifier with that object.

Enumerations (see page 617)	This section contains Enumeration topics.
Expressions (see page 619)	This section contains C++ Expression topics.
Functions (see page 624)	This section contains Function topics.
Operators Summary (see page 635)	This section contains Operator Summary topics.
Pointers (see page 637)	This section contains Pointer topics.
Postfix Expression Operators (see page 642)	This section contains Postfix Expression Operator topics.
Primary Expression Operators (see page 644)	This section contains Primary Expression Operator topics.
Statements (see page 646)	This section contains Statement topics.
Structures (see page 649)	This section contains Structure topics.
Unary Operators (see page 656)	This section contains C++ Unary Operator topics.
Unions (see page 658)	This section contains Union topics.

3.1.3.4.1 Binary Operators

This section contains Binary Operator topics.

Topics

Name	Description
Binary Operators (see page 587)	These are the binary operators in CodeGear C++:
Bitwise Operators (see page 589)	**Syntax**
C++ Specific Operators (see page 590)	The operators specific to C++ are:
Equality Operators (see page 590)	There are two equality operators: **==** and **!=**. They test for equality and inequality between arithmetic or pointer values, following rules very similar to those for the relational operators. **Note:** Notice that == and **!=** have a lower precedence than the relational operators **<** and **>**, **<=**, and **>=**. Also, **==** and **!=** can compare certain pointer types for equality and inequality where the relational operators would not be allowed. The syntax is
Logical Operators (see page 590)	**Syntax**
>, <, >=, <= Relational Operators (see page 591)	**Syntax**
Assignment Operators (see page 591)	**Syntax**
Comma Operator (see page 592)	**Syntax**
Conditional Operators (see page 592)	**Syntax**
Multiplicative Operators (see page 593)	**Syntax**

3.1.3.4.1.1 Binary Operators

These are the binary operators in CodeGear C++:

Arithmetic Operator	Description
+	Binary plus (add)
—	Binary minus (subtract)
*	Multiply
/	Divide
%	Remainder (modulus)

Bitwise Operator	Description
<<	Shift left
>>	Shift right
&	Bitwise AND

^	Bitwise XOR (exclusive OR)
|	Bitwise inclusive OR

Logical Operator	Description
&&	Logical AND

Assignment Operator	Description
=	Assignment
*=	Assign product
/=	Assign quotient
%=	Assign remainder (modulus)
+=	Assign sum
—=	Assign difference
<<=	Assign left shift
>>=	Assign right shift
&=	Assign bitwise AND
^=	Assign bitwise XOR
|=	Assign bitwise OR

Relational Operator	Description
<	Less than
>	Greater than
<=	Less than or equal to
>=	Greater than or equal to
==	Equal to
!=	Not equal to

Component Selection Operator	Description
.	Direct component selector
->	Indirect component selector

Class Member Operator	Description
::	Scope access/resolution
.*	Dereference pointer to class member

->*	Dereference pointer to class member

Conditional Operator	Description
?:	Actually a ternary operator. For example: a ? x : y means "if a then x else y"

Comma Operator	Description
,	Evaluate

3.1.3.4.1.2 Bitwise Operators

Syntax

```
AND-expression &  equality-expression
exclusive-OR-expr ^ AND-expression
inclusive-OR-expr exclusive-OR-expression
~cast-expression
shift-expression << additive-expression
shift-expression >> additive-expression
```

Remarks

Use the bitwise operators to modify the individual bits rather than the number.

Operator	What it does
&	bitwise AND; compares two bits and generates a 1 result if both bits are 1, otherwise it returns 0.
|	bitwise inclusive OR; compares two bits and generates a 1 result if either or both bits are 1, otherwise it returns 0.
^	bitwise exclusive OR; compares two bits and generates a 1 result if the bits are complementary, otherwise it returns 0.
~	bitwise complement; inverts each bit. ~ is used to create destructors.
>>	bitwise shift right; moves the bits to the right, discards the far right bit and if unsigned assigns 0 to the left most bit, otherwise sign extends.
<<	bitwise shift left; moves the bits to the left, it discards the far left bit and assigns 0 to the right most bit.

Both operands in a bitwise expression must be of an integral type.

A	B	A & B	A ^ B	A | B
0	0	0	0	0
0	1	0	1	1
1	0	0	1	1
1	1	1	0	1

Note: &, >>, << are context sensitive. & can also be the pointer reference operator.

Note: >> is often overloaded to be the input operator in I/O expressions. << is often overloaded to be the output operator in I/O expressions.

3.1.3.4.1.3 C++ Specific Operators

The operators specific to C++ are:

Operator	Meaning
::	Scope access (or resolution) operator
.*	Dereference pointers to class members
->*	Dereference pointers to pointers to class members
const_cast	adds or removes the **const** or **volatile** modifier from a type
delete	dynamically deallocates memory
dynamic_cast	converts a pointer to a desired type
new	dynamically allocates memory
reinterpret_cast	replaces casts for conversions that are unsafe or implementation dependent
static_cast	converts a pointer to a desired type
typeid	gets run-time identification of types and expressions

Use the scope access (or resolution) operator ::(two semicolons) to access a global (or file duration) name even if it is hidden by a local redeclaration of that name.

Use the .* and ->* operators to dereference pointers to class members and pointers to pointers to class members.

3.1.3.4.1.4 Equality Operators

There are two equality operators: **==** and **!=**. They test for equality and inequality between arithmetic or pointer values, following rules very similar to those for the relational operators.

Note: Notice that ==

and **!=** have a lower precedence than the relational operators **<** and **>**, **<=**, and **>=**. Also, **==** and **!=** can compare certain pointer types for equality and inequality where the relational operators would not be allowed. The syntax is

```
equality-expression:==!=
relational-expression
equality-expression == relational-expression
equality-expression != relational-expression
```

3.1.3.4.1.5 Logical Operators

Syntax

```
logical-AND-expr  && inclusive-OR-expression
logical-OR-expr   || logical-AND-expression
! cast-expression
```

Remarks

Operands in a logical expression must be of scalar type.

&& logical AND; returns **true** only if both expressions evaluate to be nonzero, otherwise returns **false**. If the first expression evaluates to **false**, the second expression is not evaluated.

|| logical OR; returns **true** if either of the expressions evaluate to be nonzero, otherwise returns **false**. If the first expression evaluates to **true**, the second expression is not evaluated.

! logical negation; returns **true** if the entire expression evaluates to be nonzero, otherwise returns **false**. The expression !E is

equivalent to (0 == E).

3.1.3.4.1.6 >, <, >=, <= Relational Operators

Syntax

```
relational-expression  <   shift-expression
relational-expression  >   shift-expression
relational-expression  <=  shift-expression
relational-expression  >=  shift-expression
```

Considerations about Relational Operators

Use relational operators to test equality or inequality of expressions. If the statement evaluates to be **true** it returns a nonzero character; otherwise it returns **false** (0).

Relational Operator	Description
>	greater than
<	less than
>=	greater than or equal to
<=	less than or equal to

In the expression:

```
E1 <operator> E2
```

the operands must follow one of these conditions:

- Both E1 and E2 are of arithmetic type.
- Both E1 and E2 are pointers to qualified or unqualified versions of compatible types.
- Either E1 or E2 is a pointer to an object or incomplete type, and the other is a pointer to a qualified or unqualified version of void.
- Either E1 or E2 is a pointer, and the other is a null pointer constant.

3.1.3.4.1.7 Assignment Operators

Syntax

```
unary-expr  assignment-op  assignment-expr
```

Remarks

The assignment operators are:

```
=    *=     /=     %=    +=    -=
<<=  >>=    &=     ^=    |=
```

The = operator is the only simple assignment operator, the others are compound assignment operators.

In the expression E1 = E2, E1 must be a modifiable lvalue. The assignment expression itself is not an lvalue.

The expression

```
E1 op= E2
```

has the same effect as

```
E1 = E1 op E2
```

except the lvalue E1 is evaluated only once. For example, E1 += E2 is the same as E1 = E1 + E2.

The expression's value is E1 after the expression evaluates.

For both simple and compound assignment, the operands E1 and E2 must obey one of the following rules:

- 1. E1 is a qualified or unqualified arithmetic type and E2 is an arithmetic type.
- 2. E1 has a qualified or unqualified version of a structure or union type compatible with the type of E2.
- 3. E1 and E2 are pointers to qualified or unqualified versions of compatible types, and the type pointed to by the left has all the qualifiers of the type pointed to by the right.
- 4. Either E1 or E2 is a pointer to an object or incomplete type and the other is a pointer to a qualified or unqualified version of void. The type pointed to by the left has all the qualifiers of the type pointed to by the right.
- 5. E1 is a pointer and E2 is a null pointer constant.

Note: Spaces separating compound operators (+<space>=) will generate errors.

Note: There are certain conditions where assignment operators are not supported when used with properties.

3.1.3.4.1.8 Comma Operator

Syntax

```
expression , assignment-expression
```

Remarks

The comma separates elements in a function argument list.

The comma is also used as an operator in comma expressions. Mixing the two uses of comma is legal, but you must use parentheses to distinguish them.

The left operand E1 is evaluated as a void expression, then E2 is evaluated to give the result and type of the comma expression. By recursion, the expression

```
E1, E2, ..., En
```

results in the left-to-right evaluation of each Ei, with the value and type of En giving the result of the whole expression.

To avoid ambiguity with the commas in function argument and initializer lists, use parentheses. For example,

```
func(i, (j = 1, j + 4), k);
```

calls func with three arguments (i, 5, k), not four.

3.1.3.4.1.9 Conditional Operators

Syntax

```
logical-OR-expr ? expr : conditional-expr
```

Remarks

The conditional operator ?: is a ternary operator.

In the expression E1 ? E2 : E3, E1 evaluates first. If its value is **true**, then E2 evaluates and E3 is ignored. If E1 evaluates to **false**, then E3 evaluates and E2 is ignored.

The result of E1 ? E2 : E3 will be the value of either E2 or E3 depending upon which evaluates.

E1 must be a scalar expression. E2 and E3 must obey one of the following rules:

- 1. Both of arithmetic type. E2 and E3 are subject to the usual arithmetic conversions, which determines the resulting type.
- 2. Both of compatible **struct** or **union** types. The resulting type is the structure or union type of E2 and E3.
- 3. Both of **void** type. The resulting type is **void**.
- 4. Both of type pointer to qualified or unqualified versions of compatible types. The resulting type is a pointer to a type

qualified with all the type qualifiers of the types pointed to by both operands.

- 5. One operand is a pointer, and the other is a null pointer constant. The resulting type is a pointer to a type qualified with all the type qualifiers of the types pointed to by both operands.
- 6. One operand is a pointer to an object or incomplete type, and the other is a pointer to a qualified or unqualified version of **void**. The resulting type is that of the non-pointer-to-**void** operand.

3.1.3.4.1.10 Multiplicative Operators

Syntax

```
multiplicative-expr * cast-expr
multiplicative-expr / cast-expr
multiplicative-expr % cast-expr
```

Remarks

There are three multiplicative operators:

- * (multiplication)
- / (division)
- % (modulus or remainder)

The usual arithmetic conversions are made on the operands.

(op1 * op2) Product of the two operands

(op1 / op2) Quotient of (op1 divided by op2)

(op1 % op2) Remainder of (op1 divided by op2)

For / and %, op2 must be nonzero op2 = 0 results in an error. (You can't divide by zero.)

When op1 and op2 are integers and the quotient is not an integer:

- 1. If op1 and op2 have the same sign, op1 / op2 is the largest integer less than the true quotient, and op1 % op2 has the sign of op1.
- 2. If op1 and op2 have opposite signs, op1 / op2 is the smallest integer greater than the true quotient, and op1 % op2 has the sign of op1.

  Note: Rounding is always toward zero.

  * is context sensitive and can be used as the pointer reference operator.

3.1.3.4.2 Declarations

This section briefly reviews concepts related to declarations: objects, storage classes, types, scope, visibility, duration, and linkage. A general knowledge of these is essential before tackling the full declaration syntax. Scope, visibility, duration, and linkage determine those portions of a program that can make legal references to an identifier in order to access its object.

Topics

Name	Description
Duration (see page 594)	Duration, closely related to storage class, defines the period during which the declared identifiers have real, physical objects allocated in memory. We also distinguish between compile-time and run-time objects. Variables, for instance, unlike **typedef**s and types, have real memory allocated during run time. There are three kinds of duration: static, local, and dynamic. **Static** Memory is allocated to objects with static duration as soon as execution is underway; this storage allocation lasts until the program terminates. All functions, wherever defined, are objects with static duration. All variables with file scope have static duration. Other variables can be given static... more (see page 594)

Linkage (see page 595)	An executable program is usually created by compiling several independent translation units, then linking the resulting object files with preexisting libraries. A problem arises when the same identifier is declared in different scopes (for example, in different files), or declared more than once in the same scope. Linkage is the process that allows each instance of an identifier to be associated correctly with one particular object or function. All identifiers have one of three linkage attributes, closely related to their scope: external linkage, internal linkage, or no linkage. These attributes are determined by the placement and format of your declarations,... more (see page 595)
Objects (see page 596)	An object is a specific region of memory that can hold a fixed or variable value (or set of values). (This use of the word object is different from the more general term used in object-oriented languages.) Each value has an associated name and type (also known as a data type). The name is used to access the object. This name can be a simple identifier, or it can be a complex expression that uniquely references the object. The type is used • to determine the correct memory allocation requirements. • to interpret the bit patterns found in the object during subsequent... more (see page 596)
Scope (see page 597)	The scope of an identifier is that part of the program in which the identifier can be used to access its object. There are six categories of scope: block (or local), function, function prototype, file, class (C++ only), condition (C++ only), and namespace (C++ only). These depend on how and where identifiers are declared. • **Block**. The scope of an identifier with block (or local) scope starts at the declaration point and ends at the end of the block containing the declaration (such a block is known as the enclosing block). Parameter declarations with a function definition also have block... more (see page 597)
Storage Classes And Types (see page 598)	Associating identifiers with objects requires each identifier to have at least two attributes: storage class and type (sometimes referred to as data type). The C++ compiler deduces these attributes from implicit or explicit declarations in the source code. Storage class dictates the location of the object and its duration or lifetime (the entire running time of the program, or during execution of some blocks of code). Storage class can be established by the syntax of the declaration, by its placement in the source code, or by both of these factors. The type determines how much memory is allocated to an... more (see page 598)
Translation Units (see page 599)	The term translation unit refers to a source code file together with any included files, but less any source lines omitted by conditional preprocessor directives. Syntactically, a translation unit is defined as a sequence of external declarations:
Visibility (see page 599)	The visibility of an identifier is that region of the program source code from which legal access can be made to the identifier's associated object. Scope and visibility usually coincide, though there are circumstances under which an object becomes temporarily hidden by the appearance of a duplicate identifier: the object still exists but the original identifier cannot be used to access it until the scope of the duplicate identifier is ended. **Note:** Visibility cannot exceed scope, but scope can exceed visibility. Again, special rules apply to hidden class names and class member names: C++ operators allow hidden identifiers to be... more (see page 599)

3.1.3.4.2.1 Duration

Duration, closely related to storage class, defines the period during which the declared identifiers have real, physical objects allocated in memory. We also distinguish between compile-time and run-time objects. Variables, for instance, unlike **typedef**s and types, have real memory allocated during run time. There are three kinds of duration: static, local, and dynamic.

Static

Memory is allocated to objects with static duration as soon as execution is underway; this storage allocation lasts until the program terminates. All functions, wherever defined, are objects with static duration. All variables with file scope have static duration. Other variables can be given static duration by using the explicit **static** or **extern** storage class specifiers.

Static duration objects are initialized to zero (or null) in the absence of any explicit initializer or, in C++, a class constructor.

Don't confuse static duration with file or global scope. An object can have static duration and local scope.

Local

Local duration objects, also known as automatic objects, lead a more precarious existence. They are created on the stack (or in a register) when the enclosing block or function is entered. They are deallocated when the program exits that block or function. Local duration objects must be explicitly initialized; otherwise, their contents are unpredictable. Local duration objects must always have local or function scope. The storage class specifier **auto** can be used when declaring local duration variables, but is usually redundant, because **auto** is the default for variables declared within a block. An object with local duration also has local scope, because it does not exist outside of its enclosing block. The converse is not true: a local scope object can have static duration.

When declaring variables (for example, **int**, **char**, **float**), the storage class specifier **register** also implies **auto**; but a request (or hint) is passed to the compiler that the object be allocated a register if possible. The compiler can be set to allocate a register to a local integral or pointer variable, if one is free. If no register is free, the variable is allocated as an **auto**, local object with no warning or error.

Note: The compiler can ignore requests for register allocation. Register allocation is based on the compiler's analysis of how a variable is used.

Dynamic

Dynamic duration objects are created and destroyed by specific function calls during a program. They are allocated storage from a special memory reserve known as the heap, using either standard library functions such as malloc, or by using the C++ operator **new**. The corresponding deallocations are made using free or **delete**.

Linkage (see page 595)

The keyword static (see page 564)

3.1.3.4.2.2 Linkage

An executable program is usually created by compiling several independent translation units, then linking the resulting object files with preexisting libraries. A problem arises when the same identifier is declared in different scopes (for example, in different files), or declared more than once in the same scope. Linkage is the process that allows each instance of an identifier to be associated correctly with one particular object or function. All identifiers have one of three linkage attributes, closely related to their scope: external linkage, internal linkage, or no linkage. These attributes are determined by the placement and format of your declarations, together with the explicit (or implicit by default) use of the storage class specifier **static** or **extern**.

Each instance of a particular identifier with external linkage represents the same object or function throughout the entire set of files and libraries making up the program. Each instance of a particular identifier with internal linkage represents the same object or function within one file only. Identifiers with no linkage represent unique entities.

External and internal linkage rules

Any object or file identifier having file scope will have internal linkage if its declaration contains the storage class specifier **static**.

For C++, if the same identifier appears with both internal and external linkage within the same file, the identifier will have external

linkage. In C, it will have internal linkage.

If the declaration of an object or function identifier contains the storage class specifier **extern**, the identifier has the same linkage as any visible declaration of the identifier with file scope. If there is no such visible declaration, the identifier has external linkage.

If a function is declared without a storage class specifier, its linkage is determined as if the storage class specifier **extern** had been used.

If an object identifier with file scope is declared without a storage class specifier, the identifier has external linkage.

Identifiers with no linkage attribute:

- Any identifier declared to be other than an object or a function (for example, a **typedef** identifier)
- Function parameters
- Block scope identifiers for objects declared without the storage class specifier **extern**

Name mangling

When a C++ module is compiled, the compiler generates function names that include an encoding of the function's argument types. This is known as name mangling. It makes overloaded functions possible, and helps the linker catch errors in calls to functions in other modules. However, there are times when you won't want name mangling. When compiling a C++ module to be linked with a module that does not have mangled names, the C++ compiler has to be told not to mangle the names of the functions from the other module. This situation typically arises when linking with libraries or .obj files compiled with a C compiler

To tell the C++ compiler not to mangle the name of a function, declare the function as extern "C", like this:

```
extern "C" void Cfunc( int );
```

This declaration tells the compiler not to mangle references to the function Cfunc.

You can also apply the extern "C" declaration to a block of names:

```
extern "C" {
   void Cfunc1( int );
   void Cfunc2( int );
   void Cfunc3( int );
};
```

As with the declaration for a single function, this declaration tells the compiler that references to the functions Cfunc1, Cfunc2, and Cfunc3 should not be mangled. You can also use this form of block declaration when the block of function names is contained in a header file:

```
extern "C" {
   #include "locallib.h"
};
```

Note: extern “C” cannot be used with class identifiers.

Declarations (see page 593)

Objects (see page 596)

Storage Classes And Types (see page 598)

Scope (see page 597)

Visibility (see page 599)

Duration (see page 594)

3.1.3.4.2.3 Objects

An object is a specific region of memory that can hold a fixed or variable value (or set of values). (This use of the word object is

different from the more general term used in object-oriented languages.) Each value has an associated name and type (also known as a data type). The name is used to access the object. This name can be a simple identifier, or it can be a complex expression that uniquely references the object. The type is used

- to determine the correct memory allocation requirements.
- to interpret the bit patterns found in the object during subsequent accesses.
- in many type-checking situations, to ensure that illegal assignments are trapped.

Borland's C++ compiler supports all standard data types, including signed and unsigned integers in various sizes, floating-point numbers in various precisions, structures, unions, arrays, and classes. In addition, pointers to most of these objects can be established and manipulated in memory.

Objects and declarations

Declarations establish the necessary mapping between identifiers and objects. Each declaration associates an identifier with a data type. Most declarations, known as defining declarations, also establish the creation (where and when) of the object; that is, the allocation of physical memory and its possible initialization. Other declarations, known as referencing declarations, simply make their identifiers and types known to the compiler. There can be many referencing declarations for the same identifier, especially in a multifile program, but only one defining declaration for that identifier is allowed.

Generally speaking, an identifier cannot be legally used in a program before its declaration point in the source code. Legal exceptions to this rule (known as forward references) are labels, calls to undeclared functions, and class, struct, or union tags.

lvalues

An lvalue is an object locator: an expression that designates an object. An example of an lvalue expression is *P, where P is any expression evaluating to a non-null pointer. A modifiable lvalue is an identifier or expression that relates to an object that can be accessed and legally changed in memory. A **const** pointer to a constant, for example, is not a modifiable lvalue. A pointer to a constant can be changed (but its dereferenced value cannot).

Historically, the l stood for "left," meaning that an lvalue could legally stand on the left (the receiving end) of an assignment statement. Now only modifiable lvalues can legally stand to the left of an assignment statement. For example, if a and b are nonconstant integer identifiers with properly allocated memory storage, they are both modifiable lvalues, and assignments such as a = 1; and b = a + b are legal.

rvalues

The expression a + b is not an lvalue: a + b = a is illegal because the expression on the left is not related to an object. Such expressions are often called rvalues (short for right values).

Declarations (see page 593)

Storage Classes And Types (see page 598)

Scope (see page 597)

Visibility (see page 599)

Duration (see page 594)

Linkage (see page 595)

3.1.3.4.2.4 Scope

The scope of an identifier is that part of the program in which the identifier can be used to access its object. There are six categories of scope: block (or local), function, function prototype, file, class (C++ only), condition (C++ only), and namespace (C++ only). These depend on how and where identifiers are declared.

- **Block**. The scope of an identifier with block (or local) scope starts at the declaration point and ends at the end of the block containing the declaration (such a block is known as the enclosing block). Parameter declarations with a function definition also have block scope, limited to the scope of the block that defines the function.
- **Function**. The only identifiers having function scope are statement labels. Label names can be used with **goto** statements

anywhere in the function in which the label is declared. Labels are declared implicitly by writing label_name: followed by a statement. Label names must be unique within a function.

- **Function prototype**. Identifiers declared within the list of parameter declarations in a function prototype (not part of a function definition) have function prototype scope. This scope ends at the end of the function prototype.
- **File**. File scope identifiers, also known as globals, are declared outside of all blocks and classes; their scope is from the point of declaration to the end of the source file.
- **Class** (C++). A class is a named collection of members, including data structures and functions that act on them. Class scope applies to the names of the members of a particular class. Classes and their objects have many special access and scoping rules; see Classes.
- **Condition** (C++). Declarations in conditions are supported. Variables can be declared within the expression of **if**, **while**, and **switch** statements. The scope of the variable is that of the statement. In the case of an **if** statement, the variable is also in scope for the **else** block.
- **namespace** (C++). A namespace is a logical grouping of program entities (e.g. identifiers, classes, and functions). Namespaces are open, that is, they can span multiple compilation units. You can think of a namespace as introducing a named scope, similar in many ways to a class in C++. See the help for the namespace keyword for more inforrmation on how to declare and use namespaces.

Name spaces

Name space is the scope within which an identifier must be unique. Note that a C++ namespace extends this concept by allowing you to give the scope a name. In addition to the named-scoping capability of C++, the C programming language uses four distinct classes of identifiers:

- **goto** label names. These must be unique within the function in which they are declared.
- Structure, union, and enumeration tags. These must be unique within the block in which they are defined. Tags declared outside of any function must be unique.
- Structure and union member names. These must be unique within the structure or union in which they are defined. There is no restriction on the type or offset of members with the same member name in different structures.
- Variables, **typedef**s, functions, and enumeration members. These must be unique within the scope in which they are defined. Externally declared identifiers must be unique among externally declared variables.

3.1.3.4.2.5 Storage Classes And Types

Associating identifiers with objects requires each identifier to have at least two attributes: storage class and type (sometimes referred to as data type). The C++ compiler deduces these attributes from implicit or explicit declarations in the source code.

Storage class dictates the location of the object and its duration or lifetime (the entire running time of the program, or during execution of some blocks of code). Storage class can be established by the syntax of the declaration, by its placement in the source code, or by both of these factors.

The type determines how much memory is allocated to an object and how the program will interpret the bit patterns found in the object's storage allocation. A given data type can be viewed as the set of values (often implementation-dependent) that identifiers of that type can assume, together with the set of operations allowed on those values. The compile-time operator, **sizeof**, lets you determine the size in bytes of any standard or user-defined type. See sizeof for more on this operator.

Scope (see page 597)

Visibility (see page 599)

Duration (see page 594)

Linkage (see page 595)

3.1.3.4.2.6 Translation Units

The term translation unit refers to a source code file together with any included files, but less any source lines omitted by conditional preprocessor directives. Syntactically, a translation unit is defined as a sequence of external declarations:

```
translation-unit:
external-declaration
translation-unit external-declaration
external-declaration
function-definition
declaration
```

word external has several connotations in C; here it refers to declarations made outside of any function, and which therefore have file scope. (External linkage is a distinct property; see the section Linkage..) Any declaration that also reserves storage for an object or function is called a definition (or defining declaration). For more details, see External declarations and definitions.

Declarations (see page 593)

Objects (see page 596)

Storage Classes And Types (see page 598)

Scope (see page 597)

Visibility (see page 599)

Duration (see page 594)

Linkage (see page 595)

3.1.3.4.2.7 Visibility

The visibility of an identifier is that region of the program source code from which legal access can be made to the identifier's associated object.

Scope and visibility usually coincide, though there are circumstances under which an object becomes temporarily hidden by the appearance of a duplicate identifier: the object still exists but the original identifier cannot be used to access it until the scope of the duplicate identifier is ended.

Note: Visibility cannot exceed scope, but scope can exceed visibility.

Again, special rules apply to hidden class names and class member names: C++ operators allow hidden identifiers to be accessed under certain conditions

3.1.3.4.3 Declaration Syntax

All six interrelated attributes (storage classes, types, scope, visibility, duration, and linkage) are determined in diverse ways by declarations.

Declarations can be defining declarations (also known as definitions) or referencing declarations (sometimes known as nondefining declarations). A defining declaration, as the name implies, performs both the duties of declaring and defining; the nondefining declarations require a definition to be added somewhere in the program. A referencing declaration introduces one or more identifier names into a program. A definition actually allocates memory to an object and associates an identifier with that object.

Topics

Name	Description
Tentative Definitions (see page 602)	The ANSI C standard supports the concept of the tentative definition. Any external data declaration that has no storage class specifier and no initializer is considered a tentative definition. If the identifier declared appears in a later definition, then the tentative definition is treated as if the **extern** storage class specifier were present. In other words, the tentative definition becomes a simple referencing declaration. If the end of the translation unit is reached and no definition has appeared with an initializer for the identifier, then the tentative definition becomes a full definition, and the object defined has uninitialized (zero-filled) space... more (see page 602)
Possible Declarations (see page 603)	The range of objects that can be declared includes • Variables • Functions • Classes and class members (C++) • Types • Structure, union, and enumeration tags • Structure members • Union members • Arrays of other types • Enumeration constants • Statement labels • Preprocessor macros The full syntax for declarations is shown in Tables 2.1 through 2.3. The recursive nature of the declarator syntax allows complex declarators. You'll probably want to use **typedefs** to improve legibility. In CodeGear C++ declaration syntax., note the restrictions on the number and order of modifiers and qualifiers. Also, the modifiers listed are the only addition to the declarator syntax that are... more (see page 603)

External Declarations and Definitions (see page 606)	The storage class specifiers auto and register cannot appear in an external declaration. For each identifier in a translation unit declared with internal linkage, no more than one external definition can be given. An external definition is an external declaration that also defines an object or function; that is, it also allocates storage. If an identifier declared with external linkage is used in an expression (other than as part of the operand of sizeof), then exactly one external definition of that identifier must exist in the entire program. The C++ compiler allows later declarations of external names, such as arrays,... more (see page 606)
Type Specifiers (see page 607)	The type determines how much memory is allocated to an object and how the program interprets the bit patterns found in the object's storage allocation. A data type is the set of values (often implementation-dependent) identifiers can assume, together with the set of operations allowed on those values. The type specifier with one or more optional modifiers is used to specify the type of the declared identifier:
Type Categories (see page 608)	Provides information on C++ type categories. The four basic type categories (and their subcategories) are as follows:
The Fundamental Types (see page 609)	The fundamental type specifiers are built from the following keywords:
Initialization (see page 611)	Initializers set the initial value that is stored in an object (variables, arrays, structures, and so on). If you don't initialize an object, and it has static duration, it will be initialized by default in the following manner: • To zero if it is an arithmetic type • To null if it is a pointer type **Note:** If the object has automatic storage duration, its value is indeterminate. **Syntax for initializers**
Declaration and Declarators (see page 612)	A **declaration** is a list of names. The names are sometimes referred to as **declarators** or identifiers. The declaration begins with optional storage class specifiers, type specifiers, and other modifiers. The identifiers are separated by commas and the list is terminated by a semicolon. Simple declarations of variable identifiers have the following pattern:
Use of Storage Class Specifiers (see page 614)	Provides information on C++ storage class specifiers. Storage classes specifiers are also called type specifiers. They dictate the location (data segment, register, heap, or stack) of an object and its duration or lifetime (the entire running time of the program, or during execution of some blocks of code). Storage class can be established by the declaration syntax, by its placement in the source code, or by both of these factors. The keyword **mutable** does not affect the lifetime of the class member to which it is applied. The storage class specifiers in C++ are: • auto (see page 533) • __declspec (see page 523) • extern (see page 549) • mutable (see page 555) • register (see page 561) • static (see page 564)... more (see page 614)
Variable Modifiers (see page 614)	In addition to the storage class specifier keywords, a declaration can use certain modifiers to alter some aspect of the identifier. The modifiers available are summarized in CodeGear C++ modifiers. The following table summarizes the effects of a modifier applied to a called function. For every modifier, the table shows the order in which the function parameters are pushed on the stack. Next, the table shows whether the calling program (the caller) or the called function (the callee) is responsible for popping the parameters off the stack. Finally, the table shows the effect on the name of a global function.... more (see page 614)

Mixed-Language Calling Conventions (see page 615)	Provides information on C++ mixed-language calling conventions. This section describes C++ mixed-language calling conventions. You can call routines written in other languages, and vice versa. When you mix languages, you have to deal with two important issues: identifiers and parameter passing. By default, the compiler saves all global identifiers in their original case (lower, upper, or mixed) with an underscore "_" prepended to the front of the identifier. To remove the default, you can use the **-u** command-line option. **Note:** The section Linkage (see page 595) tells how to use extern , which allows C names to be referenced from a C++ program.... more (see page 615)
Multithread Variables (see page 616)	The following topic describes C++ multithread variables.
Function Modifiers (see page 616)	This section presents descriptions of the function modifiers available with the CodeGear C++ compiler. You can use the __**declspec(dllexport),** and __**declspec(dllimport)**and __saveregs modifiers to modify functions. In 32-bit programs the keyword can be applied to class, function, and variable declarations The __**declspec(dllexport)** modifier makes the function exportable from Windows. The __**declspec(dllimport)** modifier makes a function available to a Windows program. The keywords are used in an executable (if you don't use smart callbacks) or in a DLL. Functions declared with the __**fastcall** modifier have different names than their non-__**fastcall** counterparts. The compiler prefixes the __**fastcall** function name with... more (see page 616)

3.1.3.4.3.1 Tentative Definitions

The ANSI C standard supports the concept of the tentative definition. Any external data declaration that has no storage class specifier and no initializer is considered a tentative definition. If the identifier declared appears in a later definition, then the tentative definition is treated as if the **extern** storage class specifier were present. In other words, the tentative definition becomes a simple referencing declaration.

If the end of the translation unit is reached and no definition has appeared with an initializer for the identifier, then the tentative definition becomes a full definition, and the object defined has uninitialized (zero-filled) space reserved for it. For example,

```
int x;
int x;          /*legal, one copy of x is reserved */
int y;
int y = 4;      /* legal, y is initialized to 4 */
int z = 5;
int z = 6;      /* not legal, both are initialized definitions */
```

Unlike ANSI C, C++ doesn't have the concept of a tentative declaration; an external data declaration without a storage class specifier is always a definition.

3.1.3.4.3.2 Possible Declarations

The range of objects that can be declared includes

- Variables
- Functions
- Classes and class members (C++)
- Types
- Structure, union, and enumeration tags
- Structure members
- Union members
- Arrays of other types
- Enumeration constants
- Statement labels
- Preprocessor macros

The full syntax for declarations is shown in Tables 2.1 through 2.3. The recursive nature of the declarator syntax allows complex declarators. You'll probably want to use **typedefs** to improve legibility.

In CodeGear C++ declaration syntax., note the restrictions on the number and order of modifiers and qualifiers. Also, the modifiers listed are the only addition to the declarator syntax that are not ANSI C or C++. These modifiers are each discussed in greater detail in Variable Modifiers and Function Modifiers.

3.1.3.4.3.3 External Declarations and Definitions

The storage class specifiers auto and register cannot appear in an external declaration. For each identifier in a translation unit declared with internal linkage, no more than one external definition can be given.

An external definition is an external declaration that also defines an object or function; that is, it also allocates storage. If an identifier declared with external linkage is used in an expression (other than as part of the operand of sizeof), then exactly one external definition of that identifier must exist in the entire program.

The C++ compiler allows later declarations of external names, such as arrays, structures, and unions, to add information to earlier declarations. Here's an example:

```
int a[];              // no size
struct mystruct;      // tag only, no member declarators
  .
  .
  .
int a[3] = {1, 2, 3}; // supply size and initialize
struct mystruct {
   int i, j;
};                    // add member declarators
```

CodeGear C++ class declaration syntax (C++ only) covers class declaration syntax. In the section on classes (beginning with Classes), you can find examples of how to declare a class. Referencing covers C++ reference types (closely related to pointer types) in detail. Finally, see Using Templates for a discussion of **template**-type classes.

3.1.3.4.3.4 Type Specifiers

The type determines how much memory is allocated to an object and how the program interprets the bit patterns found in the object's storage allocation. A data type is the set of values (often implementation-dependent) identifiers can assume, together with the set of operations allowed on those values.

The type specifier with one or more optional modifiers is used to specify the type of the declared identifier:

```
int i;                  // declare i as an integer
unsigned char ch1, ch2;  // declare two unsigned chars
```

By long-standing tradition, if the type specifier is omitted, type **signed int** (or equivalently, **int**) is the assumed default. However, in C++, a missing type specifier can lead to syntactic ambiguity, so C++ practice requires you to explicitly declare all **int** type specifiers.

The type specifier keywords by the CodeGear C++ compiler are:

char wchar_t	float	signed
class	int	struct
double	long	union

enum	short	unsigned

Use the sizeof operators to find the size in bytes of any predefined or user-defined type.

3.1.3.4.3.5 Type Categories

Provides information on C++ type categories.

The four basic type categories (and their subcategories) are as follows:

```
Aggregate   Array
   struct
   union
   class (C++ only)
Function
Scalar
   Arithmetic
   Enumeration
   Pointer
   Reference (C++ only)
void
```

Types can also be viewed in another way: they can be fundamental or derived types. The fundamental types are **void**, **char**, **int**, **float**, and **double**, together with **short**, **long**, **signed**, and **unsigned** variants of some of these. The derived types include pointers and references to other types, arrays of other types, function types, class types, structures, and unions.

A class object, for example, can hold a number of objects of different types together with functions for manipulating these objects, plus a mechanism to control access and inheritance from other classes.

Given any nonvoid type **type** (with some provisos), you can declare derived types as follows:

Declaring Types

Declaration	Description
type t;	An object of type **type**
type array[10];	Ten **type**s: array[0] - array[9]
type *ptr;	ptr is a pointer to **type**
type &ref = t;	ref is a reference to **type** (C++)
type func(**void**);	func returns value of type **type**
void func1(**type** t);	func1 takes a type **type** parameter
struct st {**type** t1;**type** t2};	structure **st** holds two **type**s

Note: type& var, type &var, and type & var are all equivalent.

Function Modifiers (see page 616)

The keyword void (see page 572)

3.1.3.4.3.6 The Fundamental Types

The fundamental type specifiers are built from the following keywords:

char	**__int8**	**long**
double	**__int16**	**signed**
float	**__int32**	**short**
int	**__int64**	**unsigned**

From these keywords you can build the integral and floating-point types, which are together known as the arithmetic types. The modifiers **long**, **short**, **signed**, and **unsigned** can be applied to the integral types. The include file limits.h contains definitions of the value ranges for all the fundamental types.

Integral types

char, **short**, **int**, and **long**, together with their unsigned variants, are all considered integral data types. Integral types shows the integral type specifiers, with synonyms listed on the same line.

Integral types

char, signed char	Synonyms if default **char** set to **signed.**
unsigned char	
char, unsigned char	Synonyms if default **char** set to **unsigned.**
signed char	
int, signed int	
unsigned, unsigned int	
short, short int, signed short int	
unsigned short, unsigned short int	
long, long int, signed long int	
unsigned long, unsigned long int	

Note: These synonyms are not valid in C++. See The three char types.

signed or **unsigned** can only be used with **char**, **short**, **int**, or **long**. The keywords **signed** and **unsigned**, when used on their own, mean **signed int** and **unsigned int**, respectively.

In the absence of **unsigned**, **signed** is assumed for integral types. An exception arises with **char**. You can set the default for **char** to be **signed** or **unsigned**. (The default, if you don't set it yourself, is **signed**.) If the default is set to **unsigned**, then the declaration char ch declares ch as **unsigned**. You would need to use signed char ch to override the default. Similarly, with a **signed** default for **char**, you would need an explicit unsigned char ch to declare an **unsigned char**.

Only **long** or **short** can be used with **int**. The keywords **long** and **short** used on their own mean **long int** and **short int**.

ANSI C does not dictate the sizes or internal representations of these types, except to indicate that **short**, **int**, and **long** form a nondecreasing sequence with **"short <= int <= long."** All three types can legally be the same. This is important if you want to write portable code aimed at other platforms.

The compiler regards the types **int** and **long** as equivalent, both being 32 bits. The signed varieties are all stored in two's complement format using the most significant bit (MSB) as a sign bit: 0 for positive, 1 for negative (which explains the ranges shown in 32-bit data types, sizes, and ranges). In the unsigned versions, all bits are used to give a range of 0 - (2n - 1), where n is 8, 16, or 32.

Floating-point types

The representations and sets of values for the floating-point types are implementation dependent; that is, each implementation of C is free to define them. The compiler uses the IEEE floating-point formats.See the topic on ANSI implementation-specific.

float and **double** are 32- and 64-bit floating-point data types, respectively. **long** can be used with **double** to declare an 80-bit precision floating-point identifier: **long double** test_case, for example.

The table of 32-bit data types, sizes, and ranges indicates the storage allocations for the floating-point types

Standard arithmetic conversions

When you use an arithmetic expression, such as a + b, where a and b are different arithmetic types, The compiler performs certain internal conversions before the expression is evaluated. These standard conversions include promotions of "lower" types to "higher" types in the interests of accuracy and consistency.

Here are the steps the compiler uses to convert the operands in an arithmetic expression:

- 1. Any small integral types are converted as shown in Methods used in standard arithmetic conversions. After this, any two values associated with an operator are either **int** (including the **long** and **unsigned** modifiers), or they are of type **double**, **float**, or **long double**.
- 2. If either operand is of type **long double**, the other operand is converted to **long double**.
- 3. Otherwise, if either operand is of type **double**, the other operand is converted to **double**.
- 4. Otherwise, if either operand is of type **float**, the other operand is converted to **float**.
- 5. Otherwise, if either operand is of type **unsigned long**, the other operand is converted to **unsigned long**.
- 6. Otherwise, if either operand is of type **long**, then the other operand is converted to **long**.
- 7. Otherwise, if either operand is of type **unsigned**, then the other operand is converted to **unsigned**.
- 8. Otherwise, both operands are of type **int**.

The result of the expression is the same type as that of the two operands.

Methods used in standard arithmetic conversions

Type	Converts to	Method
char	**int**	Zero or sign-extended (depends on default char type)
unsigned char	**int**	Zero-filled high byte (always)
signed char	**int**	Sign-extended (always)
short	**int**	Same value; sign extended
unsigned short	**unsigned int**	Same value; zero filled
enum	**int**	Same value

Special char, int, and enum conversions

Note: The conversions discussed in this section are specific to the Borland C++ compiler.

Assigning a signed character object (such as a variable) to an integral object results in automatic sign extension. Objects of type **signed char** always use sign extension; objects of type **unsigned char** always set the high byte to zero when converted to **int**.

Converting a longer integral type to a shorter type truncates the higher order bits and leaves low-order bits unchanged. Converting a shorter integral type to a longer type either sign-extends or zero-fills the extra bits of the new value, depending on whether the shorter type is **signed** or **unsigned**, respectively.

3.1.3.4.3.7 Initialization

Initializers set the initial value that is stored in an object (variables, arrays, structures, and so on). If you don't initialize an object, and it has static duration, it will be initialized by default in the following manner:

- To zero if it is an arithmetic type
- To null if it is a pointer type

Note: If the object has automatic storage duration, its value is indeterminate.

Syntax for initializers

```
initializer
        = expression
        = {initializer-list} <,>}
        (expression list)
initializer-list
        expression
        initializer-list, expression
        {initializer-list} <,>}
```

Rules governing initializers

The number of initializers in the initializer list cannot be larger than the number of objects to be initialized.

The item to be initialized must be an object (for example, an array).

For C (not required for C++), all expressions must be constants if they appear in one of these places:

In an initializer for an object that has static duration.

In an initializer list for an array, structure, or union (expressions using **sizeof** are also allowed).

- If a declaration for an identifier has block scope, and the identifier has external or internal linkage, the declaration cannot have an initializer for the identifier.
- If a brace-enclosed list has fewer initializers than members of a structure, the remainder of the structure is initialized implicitly in the same way as objects with static storage duration.

Scalar types are initialized with a single expression, which can optionally be enclosed in braces. The initial value of the object is that of the expression; the same constraints for type and conversions apply as for simple assignments.

For unions, a brace-enclosed initializer initializes the member that first appears in the union's declaration list. For structures or unions with automatic storage duration, the initializer must be one of the following:

- An initializer list (as described in Arrays, structures, and unions).
- A single expression with compatible union or structure type. In this case, the initial value of the object is that of the expression.

Arrays, structures, and unions

You initialize arrays and structures (at declaration time, if you like) with a brace-enclosed list of initializers for the members or elements of the object in question. The initializers are given in increasing array subscript or member order. You initialize unions with a brace-enclosed initializer for the first member of the union. For example, you could declare an array days, which counts how many times each day of the week appears in a month (assuming that each day will appear at least once), as follows:

```
int days[7] = { 1, 1, 1, 1, 1, 1, 1 }
```

The following rules initialize character arrays and wide character arrays:

- You can initialize arrays of character type with a literal string, optionally enclosed in braces. Each character in the string, including the null terminator, initializes successive elements in the array. For example, you could declare

*

```
char name[] = { "Unknown" };
```

which sets up an eight-element array, whose elements are 'U' (for name[0]), 'n' (for name[1]), and so on (and including a null terminator).

- You can initialize a wide character array (one that is compatible with wchar_t) by using a wide string literal, optionally enclosed in braces. As with character arrays, the codes of the wide string literal initialize successive elements of the array.

* Here is an example of a structure initialization:

```
struct mystruct {
   int i;
   char str[21];
   double d;
   } s = { 20, "Borland", 3.141 };
```

Complex members of a structure, such as arrays or structures, can be initialized with suitable expressions inside nested braces.

3.1.3.4.3.8 Declaration and Declarators

A **declaration** is a list of names. The names are sometimes referred to as **declarators** or identifiers. The declaration begins with optional storage class specifiers, type specifiers, and other modifiers. The identifiers are separated by commas and the list is

terminated by a semicolon.

Simple declarations of variable identifiers have the following pattern:

```
data-type var1 <=init1>, var2 <=init2>, ...;
```

where var1, var2,... are any sequence of distinct identifiers with optional initializers. Each of the variables is declared to be of type data-type. For example:

```
int x = 1, y = 2;
```

creates two integer variables called x and y (and initializes them to the values 1 and 2, respectively).

These are all defining declarations; storage is allocated and any optional initializers are applied.

The initializer for an automatic object can be any legal expression that evaluates to an assignment-compatible value for the type of the variable involved. Initializers for static objects must be constants or constant expressions.

In C++, an initializer for a static object can be any expression involving constants and previously declared variables and functions.

The format of the declarator indicates how the declared name is to be interpreted when used in an expression. If **type** is any type, and storage class specifier is any storage class specifier, and if D1 and D2 are any two declarators, then the declaration:

```
storage-class-specifier type D1, D2;
```

indicates that each occurrence of D1 or D2 in an expression will be treated as an object of type **type** and storage class storage class specifier. The type of the name embedded in the declarator will be some phrase containing **type**, such as "**type**," "pointer to **type**," "array of **type**," "function returning **type**," or "pointer to function returning **type**," and so on.

For example, in Declaration syntax examples each of the declarators could be used as rvalues (or possibly lvalues in some cases) in expressions where a single **int** object would be appropriate. The types of the embedded identifiers are derived from their declarators as follows:

Declaration syntax examples

Declarator syntax	Implied type of name	Example
type	name; type	**int** count;
type name[];	(open) array of **type**	**int** count[];
type name[3];	Fixed array of three elements, **int** count[3] all of **type**;	(name[0], name[1], and name[2]
type *name;	Pointer to **type**	**int** *count;
type *name[];	(open) array of pointers to **type**	**int** *count[];
type *(name[]);	Same as above	**int** *(count[]);
type (*name)[];	Pointer to an (open) array of **type**	**int** (*count) [];
type &name;	Reference to **type** (C++ only)	**int** &count;
type name();	Function returning **type**	**int** count();
type *name();	Function returning pointer to **type**	**int** *count();
type *(name());	Same as above	**int** *(count());
type (*name)();	Pointer to function returning **type**	**int** (*count) ();

Note the need for parentheses in (*name)[ ] and (*name)( ); this is because the precedence of both the array declarator [ ] and the function declarator ( ) is higher than the pointer declarator *. The parentheses in *(name[ ]) are optional.

Note: See CodeGear C++ declaration syntax for the declarator syntax. The definition covers both identifier and function

declarators.

3.1.3.4.3.9 Use of Storage Class Specifiers

Provides information on C++ storage class specifiers.

Storage classes specifiers are also called type specifiers. They dictate the location (data segment, register, heap, or stack) of an object and its duration or lifetime (the entire running time of the program, or during execution of some blocks of code).

Storage class can be established by the declaration syntax, by its placement in the source code, or by both of these factors.

The keyword **mutable** does not affect the lifetime of the class member to which it is applied.

The storage class specifiers in C++ are:

- auto (see page 533)
- __declspec (see page 523)
- extern (see page 549)
- mutable (see page 555)
- register (see page 561)
- static (see page 564)
- typedef (see page 569)

See Also

Storage Class Specifier Keywords (see page 585)

3.1.3.4.3.10 Variable Modifiers

In addition to the storage class specifier keywords, a declaration can use certain modifiers to alter some aspect of the identifier. The modifiers available are summarized in CodeGear C++ modifiers.

The following table summarizes the effects of a modifier applied to a called function. For every modifier, the table shows the order in which the function parameters are pushed on the stack. Next, the table shows whether the calling program (the caller) or the called function (the callee) is responsible for popping the parameters off the stack. Finally, the table shows the effect on the name of a global function.

Calling Conventions

Modifier	Push parameters	Pop parameters	Name change (only in C)
__cdecl1	Right to left	Caller	'_' prepended
__fastcall	Left to right	Callee	'@' prepended
__pascal	Left to right	Callee	Uppercase
__stdcall	Right to left	Callee	No change

1. This is the default.

Note: Note: __fastcall and __stdcall are always name mangled in C++. See the description of the -VC option in BCC32.

3.1.3.4.3.11 Mixed-Language Calling Conventions

Provides information on C++ mixed-language calling conventions.

This section describes C++ mixed-language calling conventions.

You can call routines written in other languages, and vice versa. When you mix languages, you have to deal with two important issues: identifiers and parameter passing.

By default, the compiler saves all global identifiers in their original case (lower, upper, or mixed) with an underscore "_" prepended to the front of the identifier. To remove the default, you can use the **-u** command-line option.

Note: The section Linkage (see page 595) tells how to use extern

, which allows C names to be referenced from a C++ program.

3.1.3.4.3.12 Multithread Variables

The following topic describes C++ multithread variables.

Topics

__thread (see page 529)

3.1.3.4.3.13 Function Modifiers

This section presents descriptions of the function modifiers available with the CodeGear C++ compiler.

You can use the **__declspec(dllexport),** and **__declspec(dllimport)**and **__**saveregs modifiers to modify functions.

In 32-bit programs the keyword can be applied to class, function, and variable declarations

The **__declspec(dllexport)** modifier makes the function exportable from Windows. The **__declspec(dllimport)** modifier makes a function available to a Windows program. The keywords are used in an executable (if you don't use smart callbacks) or in a DLL.

Functions declared with the **__fastcall** modifier have different names than their non-**__fastcall** counterparts. The compiler prefixes the **__fastcall** function name with an @. This prefix applies to both unmangled C function names and to mangled C++ function names.

CodeGear C++ modifiers

Modifier	Use with	Description
const1	Variables	Prevents changes to object.
volatile1	Variables	Prevents register allocation and some optimization. Warns compiler that object might be subject to outside change during evaluation.
__cdecl2	Functions	Forces C argument-passing convention. Affects linker and link-time names.
__cdecl2	Variables	Forces global identifier case-sensitivity and leading underscores in C.
__pascal	Functions	Forces Pascal argument-passing convention. Affects linker and link-time names.
__pascal	Variables	Forces global identifier case-insensitivity with no leading underscores in C.
__import	Functions/classes	Tells the compiler which functions or classes to import.
__export	Functions/classes	Tells the compiler which functions or classes to export.
__declspec(dllimport)	Functions/classes	Tells the compiler which functions or classes to import. This is the preferred method.
__declspec(dllexport)	Functions/classes	Tells the compiler which functions or classes to export. This is the preferred method.
__fastcall	Functions	Forces register parameter passing convention. Affects the linker and link-time names.
__stdcall	Function	Forces the standard WIN32 argument-passing convention.

1. C++ extends **const** and **volatile** to include classes and member functions.
2. This is the default.

3.1.3.4.4 Enumerations

This section contains Enumeration topics.

Topics

Name	Description
Enumerations (see page 617)	An enumeration data type is used to provide mnemonic identifiers for a set of integer values. For example, the following declaration:
Assignment To Enum Types (see page 618)	The rules for expressions involving **enum** types have been made stricter. The compiler enforces these rules with error messages if the compiler switch **-A** is turned on (which means strict ANSI C++). Assigning an integer to a variable of **enum** type results in an error:

3.1.3.4.4.1 Enumerations

An enumeration data type is used to provide mnemonic identifiers for a set of integer values. For example, the following declaration:

```
enum days { sun, mon, tues, wed, thur, fri, sat } anyday;
```

establishes a unique integral type, **enum days**, a variable anyday of this type, and a set of enumerators (sun, mon,...) with constant integer values.

The -b compiler switch controls the “Treat Enums As Ints” option. When this switch is used, the compiler allocates a whole word (a four-byte **int**) for enumeration types (variables of type **enum**). The default is ON (meaning **enums** are always **int**s) if the range of values permits, but the value is always promoted to an **int** when used in expressions. The identifiers used in an enumerator list are implicitly of type **signed char**, **unsigned char**, or **int**, depending on the values of the enumerators. If all values can be represented in a **signed** or **unsigned char**, then that is the type of each enumerator.

In C, a variable of an enumerated type can be assigned any value of type **int**--no type checking beyond that is enforced. In C++, a variable of an enumerated type can be assigned only one of its enumerators. That is:

```
anyday = mon;       // OK
anyday = 1;         // illegal, even though mon == 1
```

The identifier days is the optional enumeration tag that can be used in subsequent declarations of enumeration variables of type **enum days**:

```
enum days payday, holiday; // declare two variables
```

In C++, you can omit the **enum** keyword if **days** is not the name of anything else in the same scope.

As with **struct** and **union** declarations, you can omit the tag if no further variables of this **enum** type are required:

```
enum { sun, mon, tues, wed, thur, fri, sat } anyday;
/* anonymous enum type */
```

The enumerators listed inside the braces are also known as enumeration constants. Each is assigned a fixed integral value. In the absence of explicit initializers, the first enumerator (sun) is set to zero, and each succeeding enumerator is set to one more than its predecessor (mon = 1, tues = 2, and so on). See Enumeration constants for more on enumeration constants.

With explicit integral initializers, you can set one or more enumerators to specific values. Any subsequent names without initializers will then increase by one. For example, in the following declaration:

```
/* Initializer expression can include previously declared enumerators */
enum coins { penny = 1, tuppence, nickel = penny + 4, dime = 10,
             quarter = nickel * nickel } smallchange;
```

tuppence would acquire the value 2, nickel the value 5, and quarter the value 25.

The initializer can be any expression yielding a positive or negative integer value (after possible integer promotions). These values are usually unique, but duplicates are legal.

enum types can appear wherever **int** types are permitted.

```
enum days { sun, mon, tues, wed, thur, fri, sat } anyday;
enum days payday;
typedef enum days DAYS;
DAYS *daysptr;
int i = tues;
anyday = mon;        // OK
*daysptr = anyday;   // OK
mon = tues;          // ILLEGAL: mon is a constant
```

Enumeration tags share the same name space as structure and union tags. Enumerators share the same name space as ordinary variable identifiers:

```
int mon = 11;
{
   enum days { sun, mon, tues, wed, thur, fri, sat } anyday;
   /* enumerator mon hides outer declaration of int mon */
   struct days { int i, j;};   // ILLEGAL: days duplicate tag
   double sat;                 // ILLEGAL: redefinition of sat
}
mon = 12;                      // back in int mon scope
```

In C++, enumerators declared within a class are in the scope of that class.

In C++ it is possible to overload most operators for an enumeration. However, because the =, [ ], ( ), and -> operators must be overloaded as member functions, it is not possible to overload them for an **enum**. See the example on how to overload the postfix and prefix increment operators.

3.1.3.4.4.2 Assignment To Enum Types

The rules for expressions involving **enum** types have been made stricter. The compiler enforces these rules with error messages if the compiler switch **-A** is turned on (which means strict ANSI C++).

Assigning an integer to a variable of **enum** type results in an error:

```
enum color
{
  red, green, blue
};
int f()
{
  color c;
  c = 0;
```

```
  return c;
}
```

The same applies when passing an integer as a parameter to a function. Notice that the result type of the expression flag1|flag2 is **int**:

```
enum e
{
  flag1 = 0x01,
  flag2 = 0x02
};
void p(e);
void f()
{
  p(flag1|flag2);
}
```

To make the example compile, the expression flag1|flag2 must be cast to the **enum** type: e (flag1|flag2).

3.1.3.4.5 Expressions

This section contains C++ Expression topics.

Topics

Name	Description
Expressions (C++) (see page 620)	An expression is a sequence of operators, operands, and punctuators that specifies a computation. The formal syntax, listed in CodeGear C++ expressions, indicates that expressions are defined recursively: subexpressions can be nested without formal limit. (However, the compiler will report an out-of-memory error if it can't compile an expression that is too complex.) **Note:** CodeGear C++ expressions show how identifiers and operators are combined to form grammatically legal "phrases." Expressions are evaluated according to certain conversion, grouping, associativity, and precedence rules that depend on the operators used, the presence of parentheses, and the data types of the operands. The standard... more (see page 620)
Precedence Of Operators (see page 622)	There are 16 precedence categories, some of which contain only one operator. Operators in the same category have equal precedence with each other. Where duplicates of operators appear in the table, the first occurrence is unary, the second binary. Each category has an associativity rule: left to right, or right to left. In the absence of parentheses, these rules resolve the grouping of expressions with operators of equal precedence. The precedence of each operator in the following table is indicated by its order in the table. The first category (on the first line) has the highest precedence. Operators on the... more (see page 622)
Expressions And C++ (see page 623)	C++ allows the overloading of certain standard C operators, as explained in Overloading Operator Functions. An overloaded operator is defined to behave in a special way when applied to expressions of class type. For instance, the equality operator == might be defined in class complex to test the equality of two complex numbers without changing its normal usage with non-class data types. An overloaded operator is implemented as a function; this function determines the operand type, lvalue, and evaluation order to be applied when the overloaded operator is used. However, overloading cannot change the precedence of an operator. Similarly, C++... more (see page 623)
Evaluation Order (see page 624)	The order in which the compiler evaluates the operands of an expression is not specified, except where an operator specifically states otherwise. The compiler will try to rearrange the expression in order to improve the quality of the generated code. Care is therefore needed with expressions in which a value is modified more than once. In general, avoid writing expressions that both modify and use the value of the same object. For example, consider the expression
Errors And Overflows (see page 624)	Associativity and precedence of CodeGear C++ operators. summarizes the precedence and associativity of the operators. During the evaluation of an expression, the compiler can encounter many problematic situations, such as division by zero or out-of-range floating-point values. Integer overflow is ignored (C uses modulo 2n arithmetic on n-bit registers), but errors detected by math library functions can be handled by standard or user-defined routines.See _matherr and signal.

3.1.3.4.5.1 Expressions (C++)

An expression is a sequence of operators, operands, and punctuators that specifies a computation. The formal syntax, listed in CodeGear C++ expressions, indicates that expressions are defined recursively: subexpressions can be nested without formal limit. (However, the compiler will report an out-of-memory error if it can't compile an expression that is too complex.)

Note: CodeGear C++ expressions show how identifiers and operators are combined to form grammatically legal "phrases."

Expressions are evaluated according to certain conversion, grouping, associativity, and precedence rules that depend on the operators used, the presence of parentheses, and the data types of the operands. The standard conversions are detailed in Methods used in standard arithmetic conversions. The way operands and subexpressions are grouped does not necessarily specify the actual order in which they are evaluated by the compiler (see Evaluation order).

Expressions can produce an lvalue, an rvalue, or no value. Expressions might cause side effects whether they produce a value or not

The precedence and associativity of the operators are summarized in Associativity and precedence of CodeGear C++ operators. The grammar in CodeGear C++ expressions, completely defines the precedence and associativity of the operators.

3.1.3.4.5.2 Precedence Of Operators

There are 16 precedence categories, some of which contain only one operator. Operators in the same category have equal precedence with each other.

Where duplicates of operators appear in the table, the first occurrence is unary, the second binary. Each category has an associativity rule: left to right, or right to left. In the absence of parentheses, these rules resolve the grouping of expressions with operators of equal precedence.

The precedence of each operator in the following table is indicated by its order in the table. The first category (on the first line) has the highest precedence. Operators on the same line have equal precedence.

Operators	Associativity
() [] -> :: .	left to right
! ~ + - ++ -- & * sizeof new delete	right to left
.* ->*	left to right

* / %	left to right
+ -	left to right
<< >>	left to right
< <= > >=	left to right
== !=	left to right
&	left to right
^	left to right
|	left to right
&&	left to right
||	right to left
?:	left to right
= *= /= %= += -= &= ^= |= <<= >>=	right to left
,	left to right

3.1.3.4.5.3 Expressions And C++

C++ allows the overloading of certain standard C operators, as explained in Overloading Operator Functions. An overloaded operator is defined to behave in a special way when applied to expressions of class type. For instance, the equality operator == might be defined in class complex to test the equality of two complex numbers without changing its normal usage with non-class data types.

An overloaded operator is implemented as a function; this function determines the operand type, lvalue, and evaluation order to be applied when the overloaded operator is used. However, overloading cannot change the precedence of an operator. Similarly, C++ allows user-defined conversions between class objects and fundamental types. Keep in mind, then, that some of the C language rules for operators and conversions might not apply to expressions in C++.

3.1.3.4.5.4 Evaluation Order

The order in which the compiler evaluates the operands of an expression is not specified, except where an operator specifically states otherwise. The compiler will try to rearrange the expression in order to improve the quality of the generated code. Care is therefore needed with expressions in which a value is modified more than once. In general, avoid writing expressions that both modify and use the value of the same object. For example, consider the expression

```
i = v[i++];  // i is undefined
```

The value of i depends on whether i is incremented before or after the assignment. Similarly,

```
int total = 0;
sum = (total = 3) + (++total); // sum = 4 or sum = 7 ??
```

is ambiguous for sum and total. The solution is to revamp the expression, using a temporary variable:

```
int temp, total = 0;
temp = ++total;
sum = (total = 3) + temp;
```

Where the syntax does enforce an evaluation sequence, it is safe to have multiple evaluations:

```
sum = (i = 3, i++, i++); // OK: sum = 4, i = 5
```

Each subexpression of the comma expression is evaluated from left to right, and the whole expression evaluates to the rightmost value

The compiler regroups expressions, rearranging associative and commutative operators regardless of parentheses, in order to create an efficiently compiled expression; in no case will the rearrangement affect the value of the expression

3.1.3.4.5.5 Errors And Overflows

Associativity and precedence of CodeGear C++ operators. summarizes the precedence and associativity of the operators. During the evaluation of an expression, the compiler can encounter many problematic situations, such as division by zero or out-of-range floating-point values. Integer overflow is ignored (C uses modulo 2n arithmetic on n-bit registers), but errors detected by math library functions can be handled by standard or user-defined routines.See _matherr and signal.

3.1.3.4.6 Functions

This section contains Function topics.

Topics

Name	Description
Declarations And Definitions (see page 625)	Each program must have a single external function named main or WinMain marking the entry point of the program. Functions are usually declared as prototypes in standard or user-supplied header files, or within program files. Functions are **external** by default and are normally accessible from any file in the program. You can restrict visibility of functions by using the **static** storage class specifier (see Linkage (see page 595)). Functions are defined in your source files or made available by linking precompiled libraries. A given function can be declared several times in a program, provided the declarations are compatible. Nondefining function declarations using... more (see page 625)
The main() Function (see page 626)	

Declarations And Prototypes (see page 633)	In the Kernighan and Ritchie style of declaration, a function could be implicitly declared by its appearance in a function call, or explicitly declared as follows **<type>** func() where **type** is the optional return type defaulting to **int**. In C++, this declaration means <**type**> func(**void**). A function can be declared to return any type except an array or function type. This approach does not allow the compiler to check that the type or number of arguments used in a function call match the declaration. This problem was eased by the introduction of function prototypes with... more (see page 633)
Definitions (see page 634)	The general syntax for external function definitions is as follows: **External function definitions**
Extended Types Formatted I/O (see page 634)	The following table shows new format specifiers implemented in C++ Builder for the **printf** and **scanf** family of functions. This implementation allows the input and output of 64-bit integers and provides greater I/O flexibility for other types.
Formal Parameter Declarations (see page 635)	The formal parameter declaration list follows a syntax similar to that of the declarators found in normal identifier declarations. Here are a few examples:
Function Calls And Argument Conversions (see page 635)	A function is called with actual arguments placed in the same sequence as their matching formal parameters. The actual arguments are converted as if by initialization to the declared types of the formal parameters. Here is a summary of the rules governing how the compiler deals with language modifiers and formal parameters in function calls, both with and without prototypes: • The language modifiers for a function definition must match the modifiers used in the declaration of the function at all calls to the function. • A function can modify the values of its formal parameters, but this has no effect on... more (see page 635)

3.1.3.4.6.1 Declarations And Definitions

Each program must have a single external function named main or WinMain marking the entry point of the program. Functions are usually declared as prototypes in standard or user-supplied header files, or within program files. Functions are **external** by default and are normally accessible from any file in the program. You can restrict visibility of functions by using the **static** storage class specifier (see Linkage (see page 595)).

Functions are defined in your source files or made available by linking precompiled libraries.

A given function can be declared several times in a program, provided the declarations are compatible. Nondefining function declarations using the function prototype format provide the compiler with detailed parameter information, allowing better control over argument number and type checking, and type conversions.

Note: In C++ you must always use function prototypes. We recommend that you also use them in C.

Excluding C++ function overloading, only one definition of any given function is allowed. The declarations, if any, must also match this definition. (The essential difference between a definition and a declaration is that the definition has a function body.

3.1.3.4.6.2 The main() Function

Topics

Name	Description
About The main() Function (see page 627)	Every C and C++ program must have a program-startup function. • Console-based programs call the main function at startup. • Windows GUI programs call the WinMain function at startup. Where you place the startup function is a matter of preference. Some programmers place main at the beginning of the file, others at the end. Regardless of its location, the following points about main always apply. • Arguments to main • Wildcard arguments • Using -p (Pascal Calling Conventions) • The value that main() returns
Arguments to main() (see page 628)	Three parameters (arguments) are passed to main by the CodeGear C++Builder startup routine: **argc**, **argv**, and **env**. • **argc**, an integer, is the number of command-line arguments passed to main, including the name of the executable itself. • **argv** is an array of pointers to strings (char *[])**argv[0]** is the full path name of the program being run.**argv[1**] points to the first string typed on the operating system command line after the program name.**argv[2]** points to the second string typed after the program name.argv[argc-1] points to the last argument passed to main.**argv[argc]** contains... more (see page 628)
Default Runtime Libraries (see page 628)	BCC32.EXE is the command-line compiler. The default libraries used with this compiler are C0W32.OBJ (startup code), CW32.LIB (static single-threaded runtime library), and IMPORT32.LIB (import library for Win32).
Dynamic-link Libraries (see page 629)	The dynamic-link library (DLL) versions of the runtime library are contained in the BIN subdirectory of your installation. These are listed below indicating whether they are multithreaded. ***Directory: BIN***

Multithread Programs (see page 629)	Win32 programs can create more than one thread of execution. If your program creates multiple threads, and these threads also use the C++ runtime library, you must use the CW32MT.LIB or CW32MTI library instead. The multithread libraries provide the following functions which you use to create threads: • _beginthread • _beginthreadex • _beginthreadNT The multithread libraries also provide the following corresponding functions that terminate threads: • _endthread • _endthreadex • _threadid a global variable that contains the current identification number of the thread also known as the **thread ID**). The header file stddef.h contains the declaration of **_threadid**. When you compile or link a... more (see page 629)
Passing File Information To Child Processes (see page 630)	If your program uses the **exec** or **spawn** functions to create a new process, the new process will normally inherit all of the open file handles created by the original process. Some information, however, about these handles will be lost, including the access mode used to open the file. For example, if your program opens a file for read-only access in binary mode, and then spawns a child process, the child process might corrupt the file by writing to it, or by reading from it in text mode. To allow child processes to inherit such information about open files, you... more (see page 630)
Static Runtime Libraries (see page 630)	Listed below is each of the C++Builder static library names and its use. ***Directory of BCB\LIB (LIB files)***
The Value main() Returns (see page 632)	The value returned by **main** is the status code of the program; it must be an **int**. If, however, your program uses the routine **exit** (or **_exit**) to terminate, the value returned by main is the argument passed to the call to exit (or to _exit). For example, if your program contains the call
Using --p (Pascal Calling Conventions) (see page 632)	If you compile your program using Pascal calling conventions, you must remember to explicitly declare main as a C type. Do this with the __cdecl keyword, like this:
Wildcard Arguments (see page 632)	Command-line arguments containing wildcard characters can be expanded to all the matching file names, much the same way DOS expands wildcards when used with commands like COPY. All you have to do to get wildcard expansion is to link your program with the WILDARGS.OBJ object file, which is included with CodeGear C++. **Note:** Wildcard arguments are used only in console-mode applications. Once WILDARGS.OBJ is linked into your program code, you can send wildcard arguments (such as *.*) to your main function. The argument will be expanded (in the argv array) to all files matching the wildcard mask. The maximum... more (see page 632)

3.1.3.4.6.2.1 About The main() Function

Every C and C++ program must have a program-startup function.

- Console-based programs call the main function at startup.
- Windows GUI programs call the WinMain function at startup.

Where you place the startup function is a matter of preference. Some programmers place main at the beginning of the file, others at the end. Regardless of its location, the following points about main always apply.

- Arguments to main
- Wildcard arguments

- Using -p (Pascal Calling Conventions)
- The value that main() returns

See Also

Arguments To Main (see page 628)

Wildcard Arguments (see page 632)

Using -p (Pascal Calling Conventions) (see page 632)

The Value that main() Returns (see page 632)

3.1.3.4.6.2.2 Arguments to main()

Three parameters (arguments) are passed to main by the CodeGear C++Builder startup routine: **argc**, **argv**, and **env**.

- **argc**, an integer, is the number of command-line arguments passed to main, including the name of the executable itself.
- **argv** is an array of pointers to strings (char *[])**argv[0]** is the full path name of the program being run.**argv[1**] points to the first string typed on the operating system command line after the program name.**argv[2]** points to the second string typed after the program name.argv[argc-1] points to the last argument passed to main.**argv[argc]** contains NULL.
- **env** is also an array of pointers to strings. Each element of **env[]** holds a string of the form ENVVAR=value.ENVVAR is the name of an environment variable, such as PATHvalue is the value to which ENVVAR is set, such as C:\APPS;C:\TOOLS.

If you declare any of these parameters, you must declare them exactly in the order given: **argc**, **argv**, **env**. For example, the following are all valid declarations of arguments to **main**:

```
int main()
int main(int argc)      /* legal but very unlikely */
int main(int argc, char * argv[])
it ain(int argc, char * argv[], char * env[])]
```

The declaration int main(int argc) is legal, but it is very unlikely that you would use **argc** in your program without also using the elements of **argv.**

The argument **env** is also available through the global variable _environ..

For all platforms, **argc** and **argv** are also available via the global variables _argc and _argv.

Using main with a Unicode application

The Unicode version of the main function is:

```
int wmain (int argc, wchar_t *argv[])
```

The **argv** (and optional **envp**) parameter(s) support(s) wide-characters.

The following **_tmain** function is a macro that expands to the appropriate version of the main function depending upon the type of application:

```
int _tmain (int argc, _TCHAR *argv[])
```

3.1.3.4.6.2.3 Default Runtime Libraries

BCC32.EXE is the command-line compiler. The default libraries used with this compiler are C0W32.OBJ (startup code), CW32.LIB (static single-threaded runtime library), and IMPORT32.LIB (import library for Win32).

See Also

The main() Function (see page 627)

3.1.3.4.6.2.4 Dynamic-link Libraries

The dynamic-link library (DLL) versions of the runtime library are contained in the BIN subdirectory of your installation. These are listed below indicating whether they are multithreaded.

Directory: BIN

File Name	
CC3260.DLL	32-bit, single-threaded
CC3260MT.DLL	32-bit, multithreaded

See Also

The main() Function (see page 627)

3.1.3.4.6.2.5 Multithread Programs

Win32 programs can create more than one thread of execution. If your program creates multiple threads, and these threads also use the C++ runtime library, you must use the CW32MT.LIB or CW32MTI library instead.

The multithread libraries provide the following functions which you use to create threads:

- _beginthread
- _beginthreadex
- _beginthreadNT

The multithread libraries also provide the following corresponding functions that terminate threads:

- _endthread
- _endthreadex
- _threadid a global variable that contains the current identification number of the thread also known as the **thread ID**).

The header file stddef.h contains the declaration of _**threadid**.

When you compile or link a program that uses multiple threads, you must use the **-tWM** compiler switch. For example:

```
BCC32 -tWM THREAD.C
```

Note: Take special care when using the signal

function in a multithread program. The SIGINT, SIGTERM, and SIGBREAK signals can be used only by the main thread (thread one) in a non-Win32 application. When one of these signals occurs, the currently executing thread is suspended, and control transfers to the signal handler (if any) set up by thread one. Other signals can be handled by any thread.A signal handler should not use C++ runtime library functions, because a semaphore deadlock might occur. Instead, the handler should simply set a flag or post a semaphore, and return immediately.

_endthreadex (see page 984)

_threadid (see page 1005)

signal (see page 1000)

3.1.3.4.6.2.6 Passing File Information To Child Processes

If your program uses the **exec** or **spawn** functions to create a new process, the new process will normally inherit all of the open file handles created by the original process. Some information, however, about these handles will be lost, including the access mode used to open the file. For example, if your program opens a file for read-only access in binary mode, and then spawns a child process, the child process might corrupt the file by writing to it, or by reading from it in text mode.

To allow child processes to inherit such information about open files, you must link your program with the object file FILEINFO.OBJ.

For example:

```
BCC32 TEST.C \BCB\LIB\FILEINFO.OBJ
```

The file information is passed in the environment variable _C_FILE_INFO. This variable contains encoded binary information. Your program should not attempt to read or modify its value. The child program must have been built with the C++ runtime library to inherit this information correctly.

Other programs can ignore _C_FILE_INFO, and will not inherit file information.

The main() Function (see page 627)

3.1.3.4.6.2.8 The Value main() Returns

The value returned by **main** is the status code of the program; it must be an **int**. If, however, your program uses the routine **exit** (or _**exit**) to terminate, the value returned by main is the argument passed to the call to exit (or to _exit).

For example, if your program contains the call

```
exit(1)
the status is 1.
```

See Also

About the main() Function (see page 627)

exit (see page 1114)

_exit (see page 1097)

3.1.3.4.6.2.9 Using --p (Pascal Calling Conventions)

If you compile your program using Pascal calling conventions, you must remember to explicitly declare main as a C type. Do this with the __cdecl keyword, like this:

```
int  __cdecl main(int argc, char* argv[], char
* envp[])
```

See Also

The main() Function (see page 627)

3.1.3.4.6.2.10 Wildcard Arguments

Command-line arguments containing wildcard characters can be expanded to all the matching file names, much the same way DOS expands wildcards when used with commands like COPY. All you have to do to get wildcard expansion is to link your program with the WILDARGS.OBJ object file, which is included with CodeGear C++.

Note: Wildcard arguments are used only in console-mode applications.

Once WILDARGS.OBJ is linked into your program code, you can send wildcard arguments (such as *.*) to your main function. The argument will be expanded (in the argv array) to all files matching the wildcard mask. The maximum size of the argv array varies, depending on the amount of memory available in your heap.

If no matching files are found, the argument is passed unchanged. (That is, a string consisting of the wildcard mask is passed to **main**.)

Arguments enclosed in quotes ("...") are not expanded.

See Also

About The Main Function (see page 627)

3.1.3.4.6.3 Declarations And Prototypes

In the Kernighan and Ritchie style of declaration, a function could be implicitly declared by its appearance in a function call, or explicitly declared as follows

<type> func()

where **type** is the optional return type defaulting to **int**. In C++, this declaration means <**type**> func(**void**). A function can be declared to return any type except an array or function type. This approach does not allow the compiler to check that the type or number of arguments used in a function call match the declaration.

This problem was eased by the introduction of function prototypes with the following declaration syntax:

<type> func(parameter-declarator-list);

Note: You can enable a warning within the IDE or with the command-line compiler: "Function called without a prototype."

Declarators specify the type of each function parameter. The compiler uses this information to check function calls for validity. The compiler is also able to coerce arguments to the proper type. Suppose you have the following code fragment:

```
extern long lmax(long v1, long v2); /* prototype */
foo()
{
   int limit = 32;
   char ch = 'A';
   long mval;
   mval = lmax(limit,ch);    /* function call */
}
```

Since it has the function prototype for lmax, this program converts limit and ch to **long**, using the standard rules of assignment, before it places them on the stack for the call to lmax. Without the function prototype, limit and ch would have been placed on the stack as an integer and a character, respectively; in that case, the stack passed to lmax would not match in size or content what lmax was expecting, leading to problems. The classic declaration style does not allow any checking of parameter type or number, so using function prototypes aids greatly in tracking down programming errors.

Function prototypes also aid in documenting code. For example, the function strcpy takes two parameters: a source string and a destination string. The question is, which is which? The function prototype

```
char *strcpy(char *dest, const char *source);
```

makes it clear. If a header file contains function prototypes, then you can print that file to get most of the information you need for writing programs that call those functions. If you include an identifier in a prototype parameter, it is used only for any later error messages involving that parameter; it has no other effect.

A function declarator with parentheses containing the single word **void** indicates a function that takes no arguments at all:

```
func(void);
```

In C++, func() also declares a function taking no arguments

A function prototype normally declares a function as accepting a fixed number of parameters. For functions that accept a variable number of parameters (such as printf), a function prototype can end with an ellipsis (...), like this:

```
f(int *count, long total, ...)
```

With this form of prototype, the fixed parameters are checked at compile time, and the variable parameters are passed with no type checking.

Note: stdarg.h and varargs.h contain macros that you can use in user-defined functions with variable numbers of parameters.

Here are some more examples of function declarators and prototypes:

```
int  f();/* In C, a function returning an int with no information about parameters.
This is the K&R "classic style." */
int f();/* In C++, a function taking no arguments */
int  f(void);/* A function returning an int that takes no parameters. */
int  p(int,long);/* A function returning an int thataccepts two parameters: the first, an int;
the second, a long. */
int  __pascal q(void);/* A pascal function returningan int that takes no parameters at all. */
int  printf(char *format,...;  /*A function returning an int andaccepting a pointer to a char
fixedparameter and any number of additionalparameters of unknown type. */
int  (*fp)(int)/* A pointer to a function returning an intand requiring an int parameter. */
```

3.1.3.4.6.4 Definitions

The general syntax for external function definitions is as follows:

External function definitions

```
file
    external-definition
     file  external-definition
external-definition:
    function-definition
    declaration
    asm-statement
function-definition:
    <declaration-specifiers> declarator <declaration-list>
    compound-statement
```

In general, a function definition consists of the following sections (the grammar allows for more complicated cases):

- 1. Optional storage class specifiers: **extern** or **static**. The default is **extern**.
- 2. A return type, possibly **void**. The default is **int**.
- 3. Optional modifiers: **__pascal**, **__cdecl**, **__export**__saveregs. The defaults depend on the compiler option settings.
- 4. The name of the function.
- 5. A parameter declaration list, possibly empty, enclosed in parentheses. In C, the preferred way of showing an empty list is func(void). The old style of func is legal in C but antiquated and possibly unsafe.
- 6. A function body representing the code to be executed when the function is called.

  Note: You can mix elements from 1 and 2.

3.1.3.4.6.5 Extended Types Formatted I/O

The following table shows new format specifiers implemented in C++ Builder for the **printf** and **scanf** family of functions. This implementation allows the input and output of 64-bit integers and provides greater I/O flexibility for other types.

Format Character	Functionality
%Ld	**__int64**
%I8d	8–bit wide integer (**char**)
%I16d	16–bit wide integer (**short**)
%I32d	32–bit wide integer (**long**)
%I64d	64–bit wide integer (**__int64**)

Note that the above table uses the **%d** format as an example. The **I8, I16, I32, I64** prefixes can be used with the **d, i, o, x, X** formats, as well as the new **L** prefix previously allowed only on **float** to specify **long double** type.

3.1.3.4.6.6 Formal Parameter Declarations

The formal parameter declaration list follows a syntax similar to that of the declarators found in normal identifier declarations. Here are a few examples:

```
int func(void) {                    // no args
int func(T1 t1, T2 t2, T3 t3=1) {  // three simple parameters, one
                                    // with default argument
int func(T1* ptr1, T2& tref) {     // A pointer and a reference arg
int func(register int i) {         // Request register for arg
int func(char *str,...) {          /* One string arg with a variable number of other
                                 args, or with a fixed number of args with varying types */
```

In C++, you can give default arguments as shown. Parameters with default values must be the last arguments in the parameter list. The arguments' types can be scalars, structures, unions, or enumerations; pointers or references to structures and unions; or pointers to functions, classes, or arrays.

The ellipsis (...) indicates that the function will be called with different sets of arguments on different occasions. The ellipsis can follow a sublist of known argument declarations. This form of prototype reduces the amount of checking the compiler can make.

The parameters declared all have automatic scope and duration for the duration of the function. The only legal storage class specifier is **register**.

The **const** and **volatile** modifiers can be used with formal parameter declarators

3.1.3.4.6.7 Function Calls And Argument Conversions

A function is called with actual arguments placed in the same sequence as their matching formal parameters. The actual arguments are converted as if by initialization to the declared types of the formal parameters.

Here is a summary of the rules governing how the compiler deals with language modifiers and formal parameters in function calls, both with and without prototypes:

- The language modifiers for a function definition must match the modifiers used in the declaration of the function at all calls to the function.
- A function can modify the values of its formal parameters, but this has no effect on the actual arguments in the calling routine, except for reference arguments in C++.

When a function prototype has not been previously declared, the compiler converts integral arguments to a function call according to the integral widening (expansion) rules described in Standard arithmetic conversions. When a function prototype is in scope, the compiler converts the given argument to the type of the declared parameter as if by assignment

When a function prototype includes an ellipsis (...), the compiler converts all given function arguments as in any other prototype (up to the ellipsis). The compiler widens any arguments given beyond the fixed parameters, according to the normal rules for function arguments without prototypes.

If a prototype is present, the number of arguments must match (unless an ellipsis is present in the prototype). The types need to be compatible only to the extent that an assignment can legally convert them. You can always use an explicit cast to convert an argument to a type that is acceptable to a function prototype.

Note: If your function prototype does not match the actual function definition, the compiler will detect this if and only if that definition is in the same compilation unit as the prototype. If you create a library of routines with a corresponding header file of prototypes, consider including that header file when you compile the library, so that any discrepancies between the prototypes and the actual definitions will be caught. C++ provides type-safe linkage, so differences between expected and actual parameters will be caught by the linker.

3.1.3.4.7 Operators Summary

This section contains Operator Summary topics.

Topics

Name	Description
Operators Summary (see page 636)	Operators are tokens that trigger some computation when applied to variables and other objects in an expression. Arithmetic (see page 656) Assignment (see page 591) Bitwise (see page 589) C++ specific (see page 590) Comma (see page 592) Conditional (see page 592) Equality (see page 590) Logical (see page 590) Postfix Expression Operators Primary Expression Operators (see page 645) Preprocessor Reference/Indirect operators (see page 658) Relational (see page 591) sizeof (see page 563) typeid (see page 570) All operators can be overloaded except the following: • . C++ direct component selector • .* C++ dereference • :: C++ scope access/resolution • ?: Conditional Depending on context, the same operator can have more than one meaning. For example, the ampersand (&) can be interpreted as: • a bitwise AND (A & B) • an address operator (&A) • in C++, a reference modifier **Note:** No spaces are... more (see page 636)

3.1.3.4.7.1 Operators Summary

Operators are tokens that trigger some computation when applied to variables and other objects in an expression.

Arithmetic (see page 656)

Assignment (see page 591)

Bitwise (see page 589)

C++ specific (see page 590)

Comma (see page 592)

Conditional (see page 592)

Equality (see page 590)

Logical (see page 590)

Postfix Expression Operators

Primary Expression Operators (see page 645)

Preprocessor

Reference/Indirect operators (see page 658)

Relational (see page 591)

sizeof (see page 563)

typeid (see page 570)

All operators can be overloaded except the following:

- . C++ direct component selector
- .* C++ dereference
- :: C++ scope access/resolution
- ?: Conditional

Depending on context, the same operator can have more than one meaning. For example, the ampersand (&) can be interpreted as:

- a bitwise AND (A & B)
- an address operator (&A)
- in C++, a reference modifier

Note: No spaces are allowed in compound operators. Spaces change the meaning of the operator and will generate an error.

3.1.3.4.8 Pointers

This section contains Pointer topics.

Topics

Name	Description
Arrays (see page 638)	The declaration **type** declarator [<constant-expression>] declares an array composed of elements of **type**. An array consists of a contiguous region of storage exactly large enough to hold all of its elements. If an expression is given in an array declarator, it must evaluate to a positive constant integer. The value is the number of elements in the array. Each of the elements of an array is numbered from 0 through the number of elements minus one. Multidimensional arrays are constructed by declaring arrays of array type. The following example shows one way to declare a two-dimensional array. The implementation... more (see page 638)
C++ Reference Declarations (see page 639)	C++ reference types are closely related to pointer types. Reference types create aliases for objects and let you pass arguments to functions by reference. C passes arguments only by value. In C++ you can pass arguments by value or by reference. See Referencing (see page 452) for complete details.
Pointer Arithmetic (see page 639)	Pointer arithmetic is limited to addition, subtraction, and comparison. Arithmetical operations on object pointers of type "pointer to **type**" automatically take into account the size of **type**; that is, the number of bytes needed to store a **type** object. The internal arithmetic performed on pointers depends on the memory model in force and the presence of any overriding pointer modifiers. When performing arithmetic with pointers, it is assumed that the pointer points to an array of objects. Thus, if a pointer is declared to point to **type**, adding an integral value to the pointer advances the pointer... more (see page 639)
Pointer Constants (see page 640)	A pointer or the pointed-at object can be declared with the **const** modifier. Anything declared as a **const** cannot be have its value changed. It is also illegal to create a pointer that might violate the nonassignability of a constant object. Consider the following examples:

Pointer Conversions (see page 640)	Pointer types can be converted to other pointer types using the typecasting mechanism:
Pointer Declarations (see page 641)	A pointer must be declared as pointing to some particular type, even if that type is **void** (which really means a pointer to anything). Once declared, though, a pointer can usually be reassigned so that it points to an object of another type. The compiler lets you reassign pointers like this without typecasting, but the compiler will warn you unless the pointer was originally declared to be of type pointer to void. In C, but not C++, you can assign a **void*** pointer to a non-**void*** pointer. See void for details. **Warning:** You need to initialize pointers... more (see page 641)
Pointers (see page 641)	Pointers fall into two main categories: pointers to objects and pointers to functions. Both types of pointers are special objects for holding memory addresses. The two pointer categories have distinct properties, purposes, and rules for manipulation, although they do share certain characteristics. Generally speaking, pointers to functions are used to access functions and to pass functions as arguments to other functions; performing arithmetic on pointers to functions is not allowed. Pointers to objects, on the other hand, are regularly incremented and decremented as you scan arrays or more complex data structures in memory. Although pointers are numbers with most of... more (see page 641)
Pointers To Functions (see page 642)	A pointer to a function is best thought of as an address, usually in a code segment, where that function's executable code is stored; that is, the address to which control is transferred when that function is called. A pointer to a function has a type called "pointer to function returning **type**," where type is the function's return **type**. For example,
Pointers To Objects (see page 642)	A pointer of type "pointer to object of **type**" holds the address of (that is, points to) an object of **type**. Since pointers are objects, you can have a pointer pointing to a pointer (and so on). Other objects commonly pointed at include arrays, structures, unions, and classes.

3.1.3.4.8.1 Arrays

The declaration

type declarator [<constant-expression>]

declares an array composed of elements of **type**. An array consists of a contiguous region of storage exactly large enough to hold all of its elements.

If an expression is given in an array declarator, it must evaluate to a positive constant integer. The value is the number of elements in the array. Each of the elements of an array is numbered from 0 through the number of elements minus one.

Multidimensional arrays are constructed by declaring arrays of array type. The following example shows one way to declare a two-dimensional array. The implementation is for three rows and five columns but it can be very easily modified to accept run-time user input.

```
/* DYNAMIC MEMORY ALLOCATION FOR A MULTIDIMENSIONAL OBJECT. */
#include <stdio.h>
#include <stdlib.h>
typedef long double TYPE;
typedef TYPE *OBJECT;
unsigned int rows = 3, columns = 5;
void de_allocate(OBJECT);
int main(void) {
  OBJECT matrix;
  unsigned int i, j;
  /* STEP 1: SET UP THE ROWS. */
  matrix = (OBJECT) calloc( rows, sizeof(TYPE *));
  /* STEP 2: SET UP THE COLUMNS. */
  for (i = 0; i < rows; ++i)
    matrix[i] = (TYPE *) calloc( columns, sizeof(TYPE));
    for (i = 0; i < rows; i++)
      for (j = 0; j < columns; j++)
        matrix[i][j] = i + j;    /* INITIALIZE */
  for (i = 0; i < rows; ++i) {
    printf("\n\n");
```

```
    for (j = 0; j < columns; ++j)
      printf("%5.2Lf", matrix[i][j]);
  de_allocate(matrix);
  return 0;
  }
void de_allocate(OBJECT x) {
  int i;
  for (i = 0; i < rows; i++)    /* STEP 1: DELETE THE COLUMNS */
    free(x[i]);
  free(x);    /* STEP 2: DELETE THE ROWS. */
  }
```

This code produces the following output:

```
0.00 1.00 2.00 3.00 4.00
1.00 2.00 3.00 4.00 5.00
2.00 3.00 4.00 5.00 6.00
```

In certain contexts, the first array declarator of a series might have no expression inside the brackets. Such an array is of indeterminate size. This is legitimate in contexts where the size of the array is not needed to reserve space.

For example, an **extern** declaration of an array object does not need the exact dimension of the array; neither does an array function parameter. As a special extension to ANSI C, CodeGear C++ also allows an array of indeterminate size as the final member of a structure. Such an array does not increase the size of the structure, except that padding can be added to ensure that the array is properly aligned. These structures are normally used in dynamic allocation, and the size of the actual array needed must be explicitly added to the size of the structure in order to properly reserve space.

Except when it is the operand of a **sizeof** or **&** operator, an array type expression is converted to a pointer to the first element of the array.

Arrays

3.1.3.4.8.2 C++ Reference Declarations

C++ reference types are closely related to pointer types. Reference types create aliases for objects and let you pass arguments to functions by reference. C passes arguments only by value. In C++ you can pass arguments by value or by reference. See Referencing (see page 452) for complete details.

3.1.3.4.8.3 Pointer Arithmetic

Pointer arithmetic is limited to addition, subtraction, and comparison. Arithmetical operations on object pointers of type "pointer to **type**" automatically take into account the size of **type**; that is, the number of bytes needed to store a **type** object.

The internal arithmetic performed on pointers depends on the memory model in force and the presence of any overriding pointer modifiers.

When performing arithmetic with pointers, it is assumed that the pointer points to an array of objects. Thus, if a pointer is declared to point to **type**, adding an integral value to the pointer advances the pointer by that number of objects of **type**. If **type** has size 10 bytes, then adding an integer 5 to a pointer to **type** advances the pointer 50 bytes in memory. The difference has as its value the number of array elements separating the two pointer values. For example, if ptr1 points to the third element of an array, and ptr2 points to the tenth element, then the result of ptr2 - ptr1 would be 7.

The difference between two pointers has meaning only if both pointers point into the same array

When an integral value is added to or subtracted from a "pointer to **type**," the result is also of type "pointer to **type**."

There is no such element as "one past the last element," of course, but a pointer is allowed to assume such a value. If P points to the last array element, P + 1 is legal, but P + 2 is undefined. If P points to one past the last array element, P - 1 is legal, giving a pointer to the last element. However, applying the indirection operator * to a "pointer to one past the last element" leads to

undefined behavior.

Informally, you can think of P + n as advancing the pointer by (n * **sizeof**(**type**)) bytes, as long as the pointer remains within the legal range (first element to one beyond the last element).

Subtracting two pointers to elements of the same array object gives an integral value of type ptrdiff_t defined in stddef.h. This value represents the difference between the subscripts of the two referenced elements, provided it is in the range of ptrdiff_t. In the expression P1 - P2, where P1 and P2 are of type pointer to type (or pointer to qualified type), P1 and P2 must point to existing elements or to one past the last element. If P1 points to the i-th element, and P2 points to the j-th element, P1 - P2 has the value (i - j).

3.1.3.4.8.4 Pointer Constants

A pointer or the pointed-at object can be declared with the **const** modifier. Anything declared as a **const** cannot be have its value changed. It is also illegal to create a pointer that might violate the nonassignability of a constant object. Consider the following examples:

```
int i;                        // i is an int
int * pi;                     // pi is a pointer to int (uninitialized)
int * const cp = &i;          // cp is a constant pointer to int
const int ci = 7;             // ci is a constant int
const int * pci;              // pci is a pointer to constant int
const int * const cpc = &ci; // cpc is a constant pointer to a
                              // constant int
```

The following assignments are legal:

```
i = ci;                      // Assign const-int to int
*cp = ci;                    // Assign const-int to
                             // object-pointed-at-by-a-const-pointer
++pci;                       // Increment a pointer-to-const
pci = cpc;                   // Assign a const-pointer-to-a-const to a
                             // pointer-to-const
```

The following assignments are illegal:

```
ci = 0;                      // NO--cannot assign to a const-int
ci--;                        // NO--cannot change a const-int
*pci = 3;                    // NO--cannot assign to an object
                             // pointed at by pointer-to-const
cp = &ci;                    // NO--cannot assign to a const-pointer,
                             // even if value would be unchanged
cpc++;                       // NO--cannot change const-pointer
pi = pci;                    // NO--if this assignment were allowed,
                             // you would be able to assign to *pci
                             // (a const value) by assigning to *pi.
```

Similar rules apply to the **volatile** modifier. Note that **const** and **volatile** can both appear as modifiers to the same identifier.

3.1.3.4.8.5 Pointer Conversions

Pointer types can be converted to other pointer types using the typecasting mechanism:

```
char *str;
int *ip;
str = (char *)ip;
```

More generally, the cast (**type***) will convert a pointer to type "pointer to **type**."

See C++ specific for a discussion of C++ typecast mechanisms.

3.1.3.4.8.6 Pointer Declarations

A pointer must be declared as pointing to some particular type, even if that type is **void** (which really means a pointer to anything). Once declared, though, a pointer can usually be reassigned so that it points to an object of another type. The compiler lets you reassign pointers like this without typecasting, but the compiler will warn you unless the pointer was originally declared to be of type pointer to void. In C, but not C++, you can assign a **void*** pointer to a non-**void*** pointer. See void for details.

Warning: You need to initialize pointers before using them.

If **type** is any predefined or user-defined type, including **void**, the declaration

```
type *ptr;   /* Uninitialized pointer */
```

declares ptr to be of type "pointer to **type**." All the scoping, duration, and visibility rules apply to the ptr object just declared.

A null pointer value is an address that is guaranteed to be different from any valid pointer in use in a program. Assigning the integer constant 0 to a pointer assigns a null pointer value to it.

The mnemonic NULL (defined in the standard library header files, such as stdio.h) can be used for legibility. All pointers can be successfully tested for equality or inequality to NULL.

The pointer type "pointer to **void**" must not be confused with the null pointer. The declaration

```
void *vptr;
```

declares that vptr is a generic pointer capable of being assigned to by any "pointer to **type**" value, including null, without complaint. Assignments without proper casting between a "pointer to **type1**" and a "pointer to **type2**," where **type1** and **type2** are different types, can invoke a compiler warning or error. If **type1** is a function and **type2** isn't (or vice versa), pointer assignments are illegal. If **type1** is a pointer to **void**, no cast is needed. Under C, if **type2** is a pointer to **void**, no cast is needed.

3.1.3.4.8.7 Pointers

Pointers fall into two main categories: pointers to objects and pointers to functions. Both types of pointers are special objects for holding memory addresses.

The two pointer categories have distinct properties, purposes, and rules for manipulation, although they do share certain characteristics. Generally speaking, pointers to functions are used to access functions and to pass functions as arguments to other functions; performing arithmetic on pointers to functions is not allowed. Pointers to objects, on the other hand, are regularly incremented and decremented as you scan arrays or more complex data structures in memory.

Although pointers are numbers with most of the characteristics of unsigned integers, they have their own rules and restrictions for assignments, conversions, and arithmetic. The examples in the next few sections illustrate these rules and restrictions.

Note: See Referencing for a discussion of referencing and dereferencing.

Pointers To Objects (see page 642)

Pointers To Functions (see page 642)

Pointer Declarations (see page 641)

Pointer Constants (see page 640)

Pointer Arithmetic (see page 639)

Pointer Conversions (see page 640)

C++ Reference Declarations (see page 639)

3.1.3.4.8.8 Pointers To Functions

A pointer to a function is best thought of as an address, usually in a code segment, where that function's executable code is stored; that is, the address to which control is transferred when that function is called.

A pointer to a function has a type called "pointer to function returning **type**," where type is the function's return **type**. For example,

```
void (*func)();
```

In C++, this is a pointer to a function taking no arguments, and returning **void**. In C, it's a pointer to a function taking an unspecified number of arguments and returning **void**. In this example,

```
void (*func)(int);
```

*func is a pointer to a function taking an **int** argument and returning **void**.

For C++, such a pointer can be used to access static member functions. Pointers to class members must use pointer-to-member operators. See static_cast for details.

3.1.3.4.8.9 Pointers To Objects

A pointer of type "pointer to object of **type**" holds the address of (that is, points to) an object of **type**. Since pointers are objects, you can have a pointer pointing to a pointer (and so on). Other objects commonly pointed at include arrays, structures, unions, and classes.

3.1.3.4.9 Postfix Expression Operators

This section contains Postfix Expression Operator topics.

Topics

Name	Description
. (direct Member Selector) (see page 642)	**Syntax**
-> (indirect Member Selector) (see page 643)	**Syntax**
Array Subscript Operator (see page 643)	Brackets ([ ]) indicate single and multidimensional array subscripts. The expression
Increment/decrement Operators (see page 643)	**Increment operator (++)** Syntax
Function Call Operator (see page 644)	**Syntax**

3.1.3.4.9.1 . (direct Member Selector)

Syntax

```
postfix-expression . identifier
```

postfix-expression must be of type union or structure.

identifier must be the name of a member of that structure or union type.

Remarks

Use the selection operator (.) to access structure and union members.

Suppose that the object s is of struct type S and sptr is a pointer to S. Then, if m is a member identifier of type M declared in S, this expression:

```
s.m
```

are of type M, and represent the member object m in s.

3.1.3.4.9.2 -> (indirect Member Selector)

Syntax

```
postfix-expression -> identifier
```

postfix-expression must be of type pointer to structure or pointer to union.

identifier must be the name of a member of that structure or union type.

The expression designates a member of a structure or union object. The value of the expression is the value of the selected member it will be an lvalue if and only if the postfix expression is an lvalue.

Remarks

You use the selection operator -> to access structure and union members.

Suppose that the object s is of struct type S and sptr is a pointer to S. Then, if m is a member identifier of type M declared in S, this expression:

```
sptr->m
```

is of type M, and represents the member object m in s.

The expression

```
s->sptr
```

is a convenient synonym for (*sptr).m.

3.1.3.4.9.3 Array Subscript Operator

Brackets ([ ]) indicate single and multidimensional array subscripts. The expression

```
<exp1>[exp2]
```

is defined as

```
*((exp1) + (exp2))
```

where either:

- exp1 is a pointer and exp2 is an integer or
- exp1 is an integer and exp2 is a pointer

3.1.3.4.9.4 Increment/decrement Operators

Increment operator (++)

Syntax

```
postfix-expression ++       (postincrement)
++ unary-expression         (preincrement)
```

The expression is called the operand. It must be of scalar type (arithmetic or pointer types) and must be a modifiable lvalue..

Postincrement operator

The value of the whole expression is the value of the postfix expression before the increment is applied.

After the postfix expression is evaluated, the operand is incremented by 1.

Preincrement operator

The operand is incremented by 1 before the expression is evaluated. The value of the whole expression is the incremented value

of the operand.

The increment value is appropriate to the type of the operand.

Pointer types follow the rules for pointer arithmetic.

Decrement operator (--)

Syntax

```
postfix-expression --       (postdecrement)
-- unary-expression         (predecrement)
```

The decrement operator follows the same rules as the increment operator, except that the operand is decremented by 1 after or before the whole expression is evaluated.

3.1.3.4.9.5 Function Call Operator

Syntax

```
postfix-expression(<arg-expression-list>)
```

Remarks

Parentheses ()

- group expressions
- isolate conditional expressions
- indicate function calls and function parameters

The value of the function call expression, if it has a value, is determined by the return statement in the function definition.

This is a call to the function given by the postfix expression.

arg-expression-list is a comma-delimited list of expressions of any type representing the actual (or real) function arguments.

3.1.3.4.10 Primary Expression Operators

This section contains Primary Expression Operator topics.

Topics

Name	Description
Primary Expression Operators (see page 645)	For ANSI C, the primary expressions are literal (also sometimes referred to as constant), identifier, and (expression). The C++ language extends this list of primary expressions to include the keyword **this**, scope resolution operator **::**, name, and the class destructor **~** (tilde). The primary expressions are summarized in the following list. primary-expression: 1. literal **this** (C++ specific) 2. **::** identifier (C++ specific) 3. **::** operator-function-name (C++ specific) 4. **::** qualified-name (C++ specific) 5. (expression) name literal: 1. integer-constantcharacter-constant 2. floating-constant 3. string-literal name: 1. identifieroperator-function-name (C++ specific) 2. conversion-function-name (C++ specific) 3. **~** class-name (C++ specific) 4. qualified-name (C++ specific) qualified-name: (C++ specific) qualified-class-name **::** name For... more (see page 645)

3.1.3.4.10.1 Primary Expression Operators

For ANSI C, the primary expressions are literal (also sometimes referred to as constant), identifier, and (expression). The C++ language extends this list of primary expressions to include the keyword **this**, scope resolution operator **::**, name, and the class destructor **~** (tilde).

The primary expressions are summarized in the following list.

primary-expression:

1. literal **this** (C++ specific)
2. **::** identifier (C++ specific)
3. **::** operator-function-name (C++ specific)
4. **::** qualified-name (C++ specific)
5. (expression) name

literal:

1. integer-constantcharacter-constant
2. floating-constant
3. string-literal

name:

1. identifieroperator-function-name (C++ specific)
2. conversion-function-name (C++ specific)
3. **~** class-name (C++ specific)
4. qualified-name (C++ specific)

qualified-name: (C++ specific)

qualified-class-name **::** name

For a discussion of the primary expression **this**, see this (keyword). The keyword **this** cannot be used outside a class member function body.

The discussion of the scope resolution operator :: begins on page 104. The scope resolution operator allows reference to a type, object, function, or enumerator even though its identifier is hidden.

The parenthesis surrounding an expression do not change the unadorned expression itself.

The primary expression name is restricted to the category of primary expressions that sometimes appear after the member access operators **.** (dot) and **–>** . Therefore, name must be either an lvalue or a function. See also the discussion of member access operators.

An identifier is a primary expression, provided it has been suitably declared. The description and formal definition of identifiers is shown in Lexical Elements: Identifiers.

See the discussion on how to use the destructor operator ~ (tilde).

3.1.3.4.11 Statements

This section contains Statement topics.

Topics

Name	Description
Blocks (see page 647)	A compound statement, or block, is a list (possibly empty) of statements enclosed in matching braces (**{ }**). Syntactically, a block can be considered to be a single statement, but it also plays a role in the scoping of identifiers. An identifier declared within a block has a scope starting at the point of declaration and ending at the closing brace. Blocks can be nested to any depth up to the limits of memory.
C++ Specifics (see page 647)	C++ is an object-oriented programming language based on C. Generally speaking, you can compile C programs under C++, but you can't compile a C++ program under C if the program uses any constructs specific to C++. Some situations require special care. For example, the same function func declared twice in C with different argument types causes a duplicated name error. Under C++, however, func will be interpreted as an overloaded function; whether or not this is legal depends on other circumstances. Although C++ introduces new keywords and operators to handle classes, some of the capabilities of C++ have applications outside... more (see page 647)
Expression Statements (see page 647)	Any expression followed by a semicolon forms an expression statement:
Iteration Statements (see page 648)	Iteration statements let you loop a set of statements. There are three forms of iteration in C++: **while**, **do while**, and **for** loops.
Jump Statements (see page 648)	A jump statement, when executed, transfers control unconditionally. There are four such statements: **break**, **continue**, **goto**, and **return**

Labeled Statements (see page 648)	A statement can be labeled in two ways: • label-identifier **:** statement * The label identifier serves as a target for the unconditional **goto** statement. Label identifiers have their own name space and have function scope. In C++ you can label both declaration and non-declaration statements. • **case** constant-expression **:** statement * **default :** statement Case and default labeled statements are used only in conjunction with switch statements.
Selection Statements (see page 648)	Selection or flow-control statements select from alternative courses of action by testing certain values. There are two types of selection statements: the **if...else** and the **switch**.
Statements (see page 648)	Statements specify the flow of control as a program executes. In the absence of specific jump and selection statements, statements are executed sequentially in the order of appearance in the source code. CodeGear C++ statements shows the syntax for statements. **CodeGear C++ statements**

3.1.3.4.11.1 Blocks

A compound statement, or block, is a list (possibly empty) of statements enclosed in matching braces (**{ }**). Syntactically, a block can be considered to be a single statement, but it also plays a role in the scoping of identifiers. An identifier declared within a block has a scope starting at the point of declaration and ending at the closing brace. Blocks can be nested to any depth up to the limits of memory.

3.1.3.4.11.2 C++ Specifics

C++ is an object-oriented programming language based on C. Generally speaking, you can compile C programs under C++, but you can't compile a C++ program under C if the program uses any constructs specific to C++. Some situations require special care. For example, the same function func declared twice in C with different argument types causes a duplicated name error. Under C++, however, func will be interpreted as an overloaded function; whether or not this is legal depends on other circumstances.

Although C++ introduces new keywords and operators to handle classes, some of the capabilities of C++ have applications outside of any class context. This topic discusses the aspects of C++ that can be used independently of classes, then describes the specifics of classes and class mechanisms.

See C++ Exception Handling and C-Based Structured Exceptions for details on compiling C and C++ programs with exception handling.

See Also

Referencing (see page 452)

C++ Classes (see page 387)

Introduction To Constructors And Destructors (see page 415)

Polymorphic Classes (see page 447)

C++ Scope (see page 430)

3.1.3.4.11.3 Expression Statements

Any expression followed by a semicolon forms an expression statement:

```
<expression>;
```

The compiler executes an expression statement by evaluating the expression. All side effects from this evaluation are completed before the next statement is executed. Most expression statements are assignment statements or function calls

The null statement is a special case, consisting of a single semicolon (**;**). The null statement does nothing, and is therefore useful in situations where C++ syntax expects a statement but your program does not need one.

3.1.3.4.11.4 Iteration Statements

Iteration statements let you loop a set of statements. There are three forms of iteration in C++: **while**, **do while**, and **for** loops.

3.1.3.4.11.5 Jump Statements

A jump statement, when executed, transfers control unconditionally. There are four such statements: **break**, **continue**, **goto**, and **return**

3.1.3.4.11.6 Labeled Statements

A statement can be labeled in two ways:

- label-identifier **:** statement

* The label identifier serves as a target for the unconditional **goto** statement. Label identifiers have their own name space and have function scope. In C++ you can label both declaration and non-declaration statements.

- **case** constant-expression **:** statement

* **default :** statement

Case and default labeled statements are used only in conjunction with switch statements.

3.1.3.4.11.7 Selection Statements

Selection or flow-control statements select from alternative courses of action by testing certain values. There are two types of selection statements: the **if...else** and the **switch**.

3.1.3.4.11.8 Statements

Statements specify the flow of control as a program executes. In the absence of specific jump and selection statements, statements are executed sequentially in the order of appearance in the source code. CodeGear C++ statements shows the syntax for statements.

CodeGear C++ statements

statement	labeled-statement compound-statement expression-statement selection-statement iteration-statement jump-statement asm-statement declaration (C++ specific)
labeled-statement:	identifier : statement **case** constant-expression : statement **default** : statement

compound-statement:	{ <declaration-list> <statement-list> }
declaration-list:	declaration declaration-list declaration
statement-list:	statement statement-list statement
expression-statement:	<expression> ;
asm-statement:	**asm** tokens newline **asm** tokens; **asm** { tokens; <tokens;>= <tokens;>}
selection-statement:	**if** (expression) statement **if** (expression) statement else statement **switch** (expression) statement
iteration-statement:	**while** (expression) statement **do** statement while (expression) ; **for** (for-init-statement <expression> ; <expression>) statement
for-init-statement:	expression-statement declaration (C++ specific)
jump-statement:	**goto** identifier ; **continue** ; **break** ; **return** <expression> ;

3.1.3.4.12 Structures

This section contains Structure topics.

Topics

Name	Description
Structures (see page 650)	A structure is a derived type usually representing a user-defined collection of named members (or components). The members can be of any type, either fundamental or derived (with some restrictions to be noted later), in any sequence. In addition, a structure member can be a bit field type not allowed elsewhere. The structure type lets you handle complex data structures almost as easily as single variables. Structure initialization is discussed in Arrays, structures, and unions in the help topic Initialization (see page 611). In C++, a structure type is treated as a class type with certain differences: default access is public, and... more (see page 650)
Untagged Structures And Typedefs (see page 650)	If you omit the structure tag, you can get an untagged structure. You can use untagged structures to declare the identifiers in the comma-delimited struct-id-list to be of the given structure type (or derived from it), but you cannot declare additional objects of this type elsewhere
Structure Member Declarations (see page 651)	The member-decl-list within the braces declares the types and names of the structure members using the declarator syntax shown in CodeGear C++ declaration syntax. A structure member can be of any type, with two exceptions The member type cannot be the same as the **struct** type being currently declared:
Structures And Functions (see page 651)	A function can return a structure type or a pointer to a structure type:

Structure Member Access (see page 651)	Structure and union members are accessed using the following two selection operators: • . (period) • -> (right arrow) Suppose that the object s is of struct type S, and sptr is a pointer to S. Then if m is a member identifier of type M declared in S, the expressions s.m and sptr->m are of type M, and both represent the member object m in S. The expression sptr->m is a convenient synonym for (*sptr).m. The operator . is called the direct member selector and the operator -> is called the indirect (or pointer) member selector. For example:
Structure Name Spaces (see page 652)	Structure tag names share the same name space with union tags and enumeration tags (but **enums** within a structure are in a different name space in C++). This means that such tags must be uniquely named within the same scope. However, tag names need not differ from identifiers in the other three name spaces: the label name space, the member name space(s), and the single name space (which consists of variables, functions, **typedef** names, and enumerators). Member names within a given structure or union must be unique, but they can share the names of members in other structures or unions.... more (see page 652)
Incomplete Declarations (see page 653)	Incomplete declarations are also known as forward declarations. A pointer to a structure type A can legally appear in the declaration of another structure B before A has been declared:
Bit Fields (see page 653)	Bit fields are specified numbers of bits that may or may not have an associated identifier. Bit fields offer a way of subdividing structures (structs, unions, classes) into named parts of user-defined sizes. **Declaring bit fields** You specify the bit-field width and optional identifier as follows:

3.1.3.4.12.1 Structures

A structure is a derived type usually representing a user-defined collection of named members (or components). The members can be of any type, either fundamental or derived (with some restrictions to be noted later), in any sequence. In addition, a structure member can be a bit field type not allowed elsewhere. The structure type lets you handle complex data structures almost as easily as single variables. Structure initialization is discussed in Arrays, structures, and unions in the help topic Initialization (see page 611).

In C++, a structure type is treated as a class type with certain differences: default access is public, and the default for the base class is also public. This allows more sophisticated control over access to structure members by using the C++ access specifiers: **public** (the default), **private**, and **protected**. Apart from these optional access mechanisms, and from exceptions as noted, the following discussion on structure syntax and usage applies equally to C and C++ structures.

Structures are declared using the keyword **struct**. For example

```
struct mystruct { ... }; // mystruct is the structure tag
    .
    .
    .
struct mystruct s, *ps, arrs[10];
/* s is type struct mystruct; ps is type pointer to struct mystruct;
   arrs is array of struct mystruct. */
```

3.1.3.4.12.2 Untagged Structures And Typedefs

If you omit the structure tag, you can get an untagged structure. You can use untagged structures to declare the identifiers in the comma-delimited struct-id-list to be of the given structure type (or derived from it), but you cannot declare additional objects of

this type elsewhere

```
struct { ... } s, *ps, arrs[10]; // untagged structure
```

It is possible to create a **typedef** while declaring a structure, with or without a tag:

```
typedef struct mystruct { ... } MYSTRUCT;
MYSTRUCT s, *ps, arrs[10];       // same as struct mystruct s, etc.
typedef struct { ... } YRSTRUCT; // no tag
YRSTRUCT y, *yp, arry[20];
```

Usually, you don't need both a tag and a **typedef**: either can be used in structure declarations.

Untagged structure and union members are ignored during initialization.

3.1.3.4.12.3 Structure Member Declarations

The member-decl-list within the braces declares the types and names of the structure members using the declarator syntax shown in CodeGear C++ declaration syntax.

A structure member can be of any type, with two exceptions

The member type cannot be the same as the **struct** type being currently declared:

```
struct mystruct { mystruct s } s1, s2; // illegal
```

However, a member can be a pointer to the structure being declared, as in the following example:

```
struct mystruct { mystruct *ps } s1, s2; // OK
```

Also, a structure can contain previously defined structure types when declaring an instance of a declared structure.

Except in C++, a member cannot have the type "function returning...," but the type "pointer to function returning..." is allowed. In C++, a **struct** can have member functions.

Note: You can omit the struct

keyword in C++.

3.1.3.4.12.4 Structures And Functions

A function can return a structure type or a pointer to a structure type:

```
mystruct func1(void);  // func1() returns a structure
mystruct *func2(void); // func2() returns pointer to structure
```

A structure can be passed as an argument to a function in the following ways:

```
void func1(mystruct s);        // directly
void func2(mystruct *sptr);    // via a pointer
void func3(mystruct &sref);    // as a reference (C++ only)
```

3.1.3.4.12.5 Structure Member Access

Structure and union members are accessed using the following two selection operators:

- . (period)
- -> (right arrow)

Suppose that the object s is of struct type S, and sptr is a pointer to S. Then if m is a member identifier of type M declared in S, the expressions s.m and sptr->m are of type M, and both represent the member object m in S. The expression sptr->m is a convenient synonym for (*sptr).m.

The operator . is called the direct member selector and the operator -> is called the indirect (or pointer) member selector. For example:

```
struct mystruct
{
   int i;
   char str[21];
   double d;
} s, *sptr = &s;
    .
    .
    .
s.i = 3;            // assign to the i member of mystruct s
sptr -> d = 1.23;   // assign to the d member of mystruct s
```

The expression s.m is an lvalue, provided that s is an lvalue and m is not an array type. The expression sptr->m is an lvalue unless m is an array type.

If structure B contains a field whose type is structure A, the members of A can be accessed by two applications of the member selectors

```
struct A {
   int j;
   double x;
};
struct B {
   int i;
   struct A a;
   double d;
} s, *sptr;
    .
    .
    .
s.i = 3;            // assign to the i member of B
s.a.j = 2;          // assign to the j member of A
sptr->d = 1.23;     // assign to the d member of B
sptr->a.x = 3.14  // assign to x member of A
```

Each structure declaration introduces a unique structure type, so that in

```
struct A {
   int i,j;
   double d;
} a, a1;
struct B {
   int i,j;
   double d;
} b;
```

the objects a and a1 are both of type struct A, but the objects a and b are of different structure types. Structures can be assigned only if the source and destination have the same type:

```
a = a1;   // OK: same type, so member by member assignment
a = b;    // ILLEGAL: different types
a.i = b.i; a.j = b.j; a.d = b.d /* but you can assign member-by-member */
```

3.1.3.4.12.6 Structure Name Spaces

Structure tag names share the same name space with union tags and enumeration tags (but **enums** within a structure are in a different name space in C++). This means that such tags must be uniquely named within the same scope. However, tag names need not differ from identifiers in the other three name spaces: the label name space, the member name space(s), and the single name space (which consists of variables, functions, **typedef** names, and enumerators).

Member names within a given structure or union must be unique, but they can share the names of members in other structures or unions. For example

```
goto s;
    .
    .
```

```
    .
s:          // Label
struct s {  // OK: tag and label name spaces different
   int s;   // OK: label, tag and member name spaces different
   float s; // ILLEGAL: member name duplicated
} s;        // OK: var name space different. In C++, this can only
            // be done if s does not have a constructor.
union s {   // ILLEGAL: tag space duplicate
   int s;   // OK: new member space
   float f;
} f;        // OK: var name space
struct t {
   int s;   // OK: different member space
    .
    .
    .
} s;        // ILLEGAL: var name duplicate
```

3.1.3.4.12.7 Incomplete Declarations

Incomplete declarations are also known as forward declarations.

A pointer to a structure type A can legally appear in the declaration of another structure B before A has been declared:

```
struct A;                  // incomplete
struct B { struct A *pa };
struct A { struct B *pb };
```

The first appearance of A is called incomplete because there is no definition for it at that point. An incomplete declaration is allowed here, because the definition of B doesn't need the size of A.

3.1.3.4.12.8 Bit Fields

Bit fields are specified numbers of bits that may or may not have an associated identifier. Bit fields offer a way of subdividing structures (structs, unions, classes) into named parts of user-defined sizes.

Declaring bit fields

You specify the bit-field width and optional identifier as follows:

```
type-specifier <bitfield-id> : width;
```

In C++, type-specifier is **bool**, **char**, **unsigned char**, **short**, **unsigned short**, **long**, **unsigned long**, **int**, **unsigned int,** **__int64** or **unsigned** **__int64**. In strict ANSI C, type-specifier is **int** or **unsigned int**.

The expression width must be present and must evaluate to a constant integer. In C++, the width of a bit field may be declared of any size. In strict ANSI C, the width of a bit field may be declared only up to the size of the declared type. A zero length bit field skips to the next allocation unit.

If the bit field identifier is omitted, the number of bits specified in width is allocated, but the field is not accessible. This lets you match bit patterns in, say, hardware registers where some bits are unused.

Bit fields can be declared only in structures, unions, and classes. They are accessed with the same member selectors (. and ->) used for non-bit-field members.

Limitations of using bit fields

When using bit fields, be aware of the following issues:

- The code will be non-portable since the organization of bits-within-bytes and bytes-within-words is machine dependent.
- You cannot take the address of a bit field; so the expression &mystruct.x is illegal if x is a bit field identifier, because there is no guarantee that mystruct.x lies at a byte address.
- Bit fields are used to pack more variables into a smaller data space, but causes the compiler to generate additional code to

manipulate these variables. This costs in terms of code size and execution time.

Because of these disadvantages, using bit fields is generally discouraged, except for certain low-level programming. A recommended alternative to having one-bit variables, or flags, is to use defines. For example:

#define Nothing 0x00

#define bitOne 0x01

#define bitTwo 0x02

#define bitThree 0x04

#define bitFour 0x08

#define bitFive 0x10

#define bitSix 0x20

#define bitSeven 0x40

#define bitEight 0x80

can be used to write code like:

```
if (flags & bitOne) {...}    // is bit One turned on
flags |= bitTwo;               // turn bit Two on
flags &= ~bitThree;          // turn bit Three off
```

Similar schemes can be made for bit fields of any size.

Padding of bit fields

In C++, if the width size is larger than the type of the bit field, the compiler will insert padding equal to the requested width size minus the size of the type of the bit field. So, declaration:

```
struct mystruct
{
  int i : 40;
  int j : 8;
};
```

will create a 32 bit storage for 'i', an 8 bit padding, and 8 bit storage for 'j'. To optimize access, the compiler will consider 'i' to be a regular int variable, not a bit field.

Layout and alignment

Bit fields are broken up into groups of consecutive bit fields of the same type, without regard to signedness. Each group of bit fields is aligned to the current alignment of the type of the members of the group. This alignment is determined by the type AND by the setting of the overall alignment (set by the byte alignment option –aN). Within each group, the compiler will pack the bit fields inside of areas as large as the type size of the bit fields. However, no bit field is allowed to straddle the boundary between 2 of those areas. The size of the total structure will be aligned, as determined by the current alignment.

Example of bit field layout, padding, and alignment

In the following C++ declaration, my_struct contains 6 bit fields of 3 different types, **int**, **long**, and **char**:

```
struct my_struct
{
   int one : 8;
   unsigned int two : 16;
   unsigned long three : 8;
   long four : 16;
   long five : 16;
   char six : 4;
};
```

Bit fields 'one' and 'two' will be packed into one 32-bit area.

Next, the compiler inserts padding, if necessary, based on the current alignment, and the type of three, because the type

changes between the declarations of variables two and three. For example, if the current alignment is byte alignment (-a1), no padding is needed; whereas, if the alignment is 4 bytes (-a4), then 8-bit padding is inserted.

Next, variables three, four, and five are all of type **long**. Variables three and four are packed into one 32 bit area, but five can not be packed into that same area, since that would create an area of 40 bits, which is more than the 32 bit allowed for the **long** type. To start a new area for five, the compiler would insert no padding if the current alignment is byte alignment, or would insert 8 bits of padding if the current alignment is dword (4 byte) alignment.

With variable six, the type changes again. Since **char** is always byte aligned, no padding is needed. To force alignment for the whole struct, the compiler will finish up the last area with 4 bits of padding if byte alignment is used, or 12 bits of padding if dword alignment is used.

The total size of my_struct is 9 bytes with byte alignment, or 12 bytes with dword alignment.

To get the best results when using bit fields you should:

- Sort bit fields by type
- Make sure they are packed inside the areas by ordering them such that no bit field will straddle an area boundary
- Make sure the struct is filled as much as possible.

Another recommendation is to force byte alignment for this struct, by emitting "#pragma option -a1". If you want to know how big your struct is, follow it by "#pragma sizeof(mystruct)", which gives you the size.

Using one bit signed fields

For a signed type of one bit, the possible values are 0 or –1. For an unsigned type of one bit, the possible values are 0 or 1. Note that if you assign “1” to a signed bit field, the value will be evaluated as –1 (negative one).

When storing the values **true** and **false** into a one bit sized bit field of a signed type, you can not test for equality to **true** because signed one bit sized bit fields can only hold the values '0' and '-1', which are not compatible with **true** and **false**. You can, however, test for non-zero.

For unsigned varieties of all types, and of course for the **bool** type, testing for equality to **true** will work as expected.

Thus:

```
struct mystruct
{
   int flag : 1;
} M;
int testing()
{
   M.flag = true;
   if(M.flag == true)
     printf("success");}
```

will NOT work, but:

```
struct mystruct
{
   int flag : 1;
} M;
int testing()
{
   M.flag = true;
   if(M.flag)
     printf("success");
}
```

works just fine.

Notes on compatibility

Between versions of the compiler, changes can be made to default alignment, or for purposes of compatibility with other compilers. Consequently, this could change the alignment of bit fields. Therefore, there is no guarantee that the alignment of bit

fields will be consistent between versions of the compiler. To check the backward compatibility of bit fields in your code you can add an assert statement that checks for the structure size you are expecting.

According to the C and C++ language specifications, the alignment and storage of bit fields is implementation defined. Therefore, compilers can align and store bit fields differently. If you want complete control over the layout of bit fields, it is advisable to write your own bit field accessing routines and create your own bit fields.

3.1.3.4.13 Unary Operators

This section contains C++ Unary Operator topics.

Topics

Name	Description
Unary Operators (see page 656)	**Syntax**
Arithmetic Operators (see page 656)	**Syntax**
Plus And Minus Operators (see page 657)	**Unary** In these unary + - expressions
Reference/Deference Operators (see page 658)	**Syntax**

3.1.3.4.13.1 Unary Operators

Syntax

```
<unary-operator> <unary expression>
```

OR

```
<unary-operator> <type><unary expression>
```

Remarks

Unary operators group right-to-left.

The C++ language provides the following unary operators:

- ! Logical negation
- * Indirection
- ++ Increment
- ~ Bitwise complement
- -- Decrement
- - Unary minus
- + Unary plus

3.1.3.4.13.2 Arithmetic Operators

Syntax

```
+ cast-expression
- cast-expression
add-expression + multiplicative-expression
add-expression - multiplicative-expression
multiplicative-expr * cast-expr
multiplicative-expr / cast-expr
multiplicative-expr % cast-expr
postfix-expression ++       (postincrement)
++ unary-expression         (preincrement)
postfix-expression --       (postdecrement)
-- unary-expression         (predecrement)
```

Remarks

Use the arithmetic operators to perform mathematical computations.

The unary expressions of + and - assign a positive or negative value to the cast-expression.

- (addition), - (subtraction), * (multiplication), and / (division) perform their basic algebraic arithmetic on all data types, integer and floating point.

% (modulus operator) returns the remainder of integer division and cannot be used with floating points.

++ (increment) adds one to the value of the expression. Postincrement adds one to the value of the expression after it evaluates; while preincrement adds one before it evaluates.

-- (decrement) subtracts one from the value of the expression. Postdecrement subtracts one from the value of the expression after it evaluates; while predecrement subtracts one before it evaluates.

3.1.3.4.13.3 Plus And Minus Operators

Unary

In these unary + - expressions

```
+ cast-expression
- cast-expression
```

the cast-expression operand must be of arithmetic type.

Results

- cast-expression Value of the operand after any required integral promotions.
- cast-expression Negative of the value of the operand after any required integral promotions.

Binary

Syntax

```
add-expression + multiplicative-expression
add-expression - multiplicative-expression
```

Legal operand types for op1 + op2:

- 1. Both op1 and op2 are of arithmetic type.
- 2. op1 is of integral type, and op2 is of pointer to object type.
- 3. op2 is of integral type, and op1 is of pointer to object type.

In case 1, the operands are subjected to the standard arithmetical conversions, and the result is the arithmetical sum of the operands.

In cases 2 and 3, the rules of pointer arithmetic apply.

Legal operand types for op1 - op2:

- 1. Both op1 and op2 are of arithmetic type.
- 2. Both op1 and op2 are pointers to compatible object types.
- 3. op1 is of pointer to object type, and op2 is integral type.

In case 1, the operands are subjected to the standard arithmetic conversions, and the result is the arithmetic difference of the operands.

In cases 2 and 3, the rules of pointer arithmetic apply.

Note: The unqualified type <type> is considered to be compatible with the qualified types const type, volatile type,and const volatile type.

3.1.3.4.13.4 Reference/Deference Operators

Syntax

```
& cast-expression
* cast-expression
```

Remarks

The **&** and ***** operators work together to reference and dereference pointers that are passed to functions.

Referencing operator (&)

Use the reference operator to pass the address of a pointer to a function outside of main().

The cast-expression operand must be one of the following:

- a function designator
- an lvalue designating an object that is not a bit field and is not declared with a register storage class specifier

If the operand is of type <type>, the result is of type pointer to <type>.

Some non-lvalue identifiers, such as function names and array names, are automatically converted into “pointer-to-X” types when they appear in certain contexts. The **&** operator can be used with such objects, but its use is redundant and therefore discouraged.

Consider the following example:

```
T t1 = 1, t2 = 2;
T *ptr = &t1;      // Initialized pointer
*ptr = t2;           // Same effect as t1 = t2
```

T *ptr = &t1 is treated as

```
T *ptr;
ptr = &t1;
```

So it is ptr, or *ptr, that gets assigned. Once ptr has been initialized with the address &t1, it can be safely dereferenced to give the lvalue *ptr.

Indirection operator (*)

Use the asterisk (*****) in a variable expression to create pointers. And use the indirect operator in external functions to get a pointer's value that was passed by reference.

If the operand is of type pointer to function, the result is a function designator.

If the operand is a pointer to an object, the result is an lvalue designating that object.

The result of indirection is undefined if either of the following occur:

- 1. The cast-expression is a null pointer.
- 2. The cast-expression is the address of an automatic variable and execution of its block has terminated.

Note: & can also be the bitwise AND operator.

Note: * can also be the multiplication operator.

3.1.3.4.14 Unions

This section contains Union topics.

Topics

Name	Description
Unions (see page 659)	Union types are derived types sharing many of the syntactic and functional features of structure types. The key difference is that a union allows only one of its members to be "active" at any one time. The size of a union is the size of its largest member. The value of only one of its members can be stored at any time. In the following simple case,
Anonymous Unions (see page 659)	A union that does not have a tag and is not used to declare a named object (or other type) is called an anonymous union. It has the following form:
Union Declarations (see page 660)	The general declaration syntax for unions is similar to that for structures. The differences are: • Unions can contain bit fields, but only one can be active. They all start at the beginning of the union. (Note that, because bit fields are machine dependent, they can pose problems when writing portable code.) • Unlike C++ structures, C++ union types cannot use the class access specifiers: **public**, **private**, and **protected**. All fields of a union are public. • Unions can be initialized only through their first declared member:

3.1.3.4.14.1 Unions

Union types are derived types sharing many of the syntactic and functional features of structure types. The key difference is that a union allows only one of its members to be "active" at any one time. The size of a union is the size of its largest member. The value of only one of its members can be stored at any time. In the following simple case,

```
union myunion {     /* union tag = myunion */
   int i;
   double d;
   char ch;
} mu, *muptr=&mu;
```

the identifier mu, of type **union** myunion, can be used to hold an **int**, an 8-byte **double**, or a single-byte **char**, but only one of these at the same time

Note: Unions correspond to the variant record types of Delphi.

sizeof(**union** myunion) and **sizeof**(mu) both return 8, but 4 bytes are unused (padded) when mu holds an **int** object, and 7 bytes are unused when mu holds a **char**. You access union members with the structure member selectors (. and ->), but care is needed:

```
mu.d = 4.016;
printf("mu.d = %f\n",mu.d); //OK: displays mu.d = 4.016printf("mu.i = %d\n",mu.i); //peculiar resultmu.ch = 'A';
printf("mu.ch = %c\n",mu.ch); //OK: displays mu.ch = Aprintf("mu.d = %f\n",mu.d); //peculiar resultmuptr->i = 3;
printf("mu.i = %d\n",mu.i); //OK: displays mu.i = 3
```

The second printf is legal, since mu.i is an integer type. However, the bit pattern in mu.i corresponds to parts of the **double** previously assigned, and will not usually provide a useful integer interpretation.

When properly converted, a pointer to a union points to each of its members, and vice versa.

3.1.3.4.14.2 Anonymous Unions

A union that does not have a tag and is not used to declare a named object (or other type) is called an anonymous union. It has the following form:

```
union { member-list };
```

Its members can be accessed directly in the scope where this union is declared, without using the x.y or p->y syntax.

Anonymous unions can be global, nested, or unnested. ANSI-C never allows anonymous unions. ANSI-C++ allows all three types of anonymous unions.

C++ Anonymous unions

An anonymous union cannot have member functions or private or protected members. At file level an anonymous union must be declared static. Local anonymous unions must be either automatic or static; in other words, an anonymous union cannot have external linkage. Unnested anonymous unions are only allowed in C++.

Nested anonymous unions

The outer structure, class, or union of a nested anonymous union must have a tag. CodeGear C and C++ allow nested anonymous unions by default. In C only, a nested anonymous union can, optionally, have a tag.

Example

```
struct outer {
        int x;
};
int main(void)
{
        struct outer o;
}
```

3.1.3.4.14.3 Union Declarations

The general declaration syntax for unions is similar to that for structures. The differences are:

- Unions can contain bit fields, but only one can be active. They all start at the beginning of the union. (Note that, because bit fields are machine dependent, they can pose problems when writing portable code.)
- Unlike C++ structures, C++ union types cannot use the class access specifiers: **public**, **private**, and **protected**. All fields of a union are public.
- Unions can be initialized only through their first declared member:

```
union local87 {
  int i;
  double d;
  } a = { 20 };
```

A union can't participate in a class hierarchy. It can't be derived from any class, nor can it be a base class. A union can have a constructor.

3.1.3.5 Lexical Elements

This section contains Lexical Element topics.

Topics

Name	Description
Lexical Elements (see page 661)	These topics provide a formal definition of C++ lexical elements. They describe the different categories of word-like units (tokens) recognized by a language. The tokens in a C++ source file are derived from a series of operations performed on your programs by the compiler and its built-in preprocessor. The preprocessor first scans the program text for special preprocessor directives (see Preprocessor directives for details). For example, the directive **#include** <inc_file> adds (or includes) the contents of the file inc_file to the program before the compilation phase. The preprocessor also expands any macros found in the program and include files. A... more (see page 661)

Tokens Overview (see page 661)	This section contains Token topics.
Whitespace Overview (see page 684)	This section contains Whitespace Overview topics.

3.1.3.5.1 Lexical Elements

These topics provide a formal definition of C++ lexical elements. They describe the different categories of word-like units (tokens) recognized by a language.

The tokens in a C++ source file are derived from a series of operations performed on your programs by the compiler and its built-in preprocessor.

The preprocessor first scans the program text for special preprocessor directives (see Preprocessor directives for details). For example, the directive **#include** <inc_file> adds (or includes) the contents of the file inc_file to the program before the compilation phase. The preprocessor also expands any macros found in the program and include files.

A C++ program starts as a sequence of ASCII characters representing the source code, created using a suitable text editor (such as the IDE's editor). The basic program unit in C++ is a source file (usually designated by a ".c", or ".cpp" in its name), and all of the header files and other source files included with the **#include** preprocessor directive. Source files are usually designated by a ".c" or ".cpp" in the name, while header files are usually designated with a ".h" or ".hpp".

In the tokenizing phase of compilation, the source code file is parsed (that is, broken down) into tokens and whitespace.

3.1.3.5.2 Tokens Overview

This section contains Token topics.

Topics

Name	Description
Constants Overview (see page 662)	This section contains Constant topics.
Tokens (see page 678)	Tokens are word-like units recognized by a language. The compiler recognizes six classes of tokens. Here is the formal definition of a token: • keyword • identifier • constant • string-literal • operator • punctuator (also known as separators) As the source code is scanned, tokens are extracted in such a way that the longest possible token from the character sequence is selected. For example, external would be parsed as a single identifier, rather than as the keyword **extern** followed by the identifier al. See Token Pasting with ## for a description of token pasting.
Identifiers Overview (see page 679)	This section contains Identifier topics.
Keywords Overview (see page 680)	This section contains Keyword topics.
Punctuators Overview (see page 681)	This section contains Punctuator topics.

3.1.3.5.2.1 Constants Overview

This section contains Constant topics.

Topics

Name	Description
Character Constants Overview (see page 662)	This section contains Character Constant topics.
Constants (see page 667)	Constants are tokens representing fixed numeric or character values. The compiler supports four classes of constants: integer, floating point, character (including strings), and enumeration. Internal representation of numerical types shows how these types are represented internally. The data type of a constant is deduced by the compiler using such clues as numeric value and the format used in the source code. The formal definition of a constant is shown in the following table. ***Constants: Formal Definitions***
Integer Constant Without L Or U (see page 669)	***Decimal constants***
Constant Expressions (see page 670)	This section contains Constant Expression topics.
Constants and Internal Representation (see page 670)	This section contains Constants and Internal Representation topics.
Floating Point Constants (see page 672)	A floating-point constant consists of: • Decimal integer • Decimal point • Decimal fraction • e or E and a signed integer exponent (optional) • Type suffix: f or F or l or L (optional) You can omit either the decimal integer or the decimal fraction (but not both). You can omit either the decimal point or the letter e (or E) and the signed integer exponent (but not both). These rules allow for conventional and scientific (exponent) notations. Negative floating constants are taken as positive constants with the unary operator minus (-) prefixed. Here are some examples:
Enumeration Constants (see page 673)	This section contains Enumeration Constant topics.
Integer Constants (see page 674)	Integer constants can be decimal (base 10), octal (base 8) or hexadecimal (base 16). In the absence of any overriding suffixes, the data type of an integer constant is derived from its value, as shown in Integer constants without L or U.. Note that the rules vary between decimal and nondecimal constants. **Decimal** Decimal constants from 0 to 4,294,967,295 are allowed. Constants exceeding this limit are truncated. Decimal constants must not use an initial zero. An integer constant that has an initial zero is interpreted as an octal constant. Thus,
Internal Representation of Numerical Types (see page 675)	This section contains Internal Representation of Numerical Type topics.
String Constants (see page 677)	This section contains String Constant topics.

3.1.3.5.2.1.1 Character Constants Overview

This section contains Character Constant topics.

Topics

Name	Description
Character Constants (see page 663)	A character constant is one or more characters enclosed in single quotes, such as 'A', '+', or '\n'. In C, single-character constants have data type **int**. In C++, a character constant has type **char**. Multicharacter constants in both C and C++ have data type **int**. To learn more about character constants, see the following topics. • Three char types (see page 666) • Escape sequences (see page 664) • Wide-character and multi-character constants (see page 666) **Note:** To compare sizes of character types, compile this as a C program and then as a C++ program.
Escape Sequences (see page 664)	The backslash character (\) is used to introduce an escape sequence, which allows the visual representation of certain nongraphic characters. For example, the constant **\n** is used to the single newline character. A backslash is used with octal or hexadecimal numbers to represent the ASCII symbol or control code corresponding to that value; for example, '\03' for Ctrl-C or '\x3F' for the question mark. You can use any string of up to three octal or any number of hexadecimal numbers in an escape sequence, provided that the value is within legal range for data type **char** (0 to 0xff). Larger... more (see page 664)
The Three Char Types (see page 666)	One-character constants, such as 'A', '\t' and '007', are represented as **int** values. In this case, the low-order byte is sign extended into the high bit; that is, if the value is greater than 127 (base 10), the upper bit is set to -1 (=0xFF). This can be disabled by declaring that the default **char** type is **unsigned.** The three character types, **char**, **signed char**, and **unsigned char,** require an 8-bit (one byte) storage. By default, the compiler treats character declarations as signed. Use the –K compiler option to treat character declarations as unsigned. The behavior of C... more (see page 666)
Wide-character And Multi-character Constants (see page 666)	Wide-character types can be used to represent a character that does not fit into the storage space allocated for a **char** type. A wide character is stored in a two-byte space. A character constant preceded immediately by an L is a wide-character constant of data type wchar_t (defined in stddef.h). For example:

3.1.3.5.2.1.1.1 Character Constants

A character constant is one or more characters enclosed in single quotes, such as 'A', '+', or '\n'. In C, single-character constants have data type **int**. In C++, a character constant has type **char**. Multicharacter constants in both C and C++ have data type **int**.

To learn more about character constants, see the following topics.

- Three char types (see page 666)
- Escape sequences (see page 664)
- Wide-character and multi-character constants (see page 666)

Note: To compare sizes of character types, compile this as a C program and then as a C++ program.

```
#include <stdio.h>
#define CH 'x'       /* A CHARACTER CONSTANT */
void main(void) {
   char ch = 'x';    /* A char VARIABLE      */
   printf("\nSizeof int     = %d", sizeof(int) );
   printf("\nSizeof char    = %d", sizeof(char) );
   printf("\nSizeof ch      = %d", sizeof(ch) );
   printf("\nSizeof CH      = %d", sizeof(CH) );
   printf("\nSizeof wchar_t = %d", sizeof(wchar_t) );
}
```

Note: Sizes are in bytes.

Sizes of character types

Output when compiled as C program	Output when compiled as C++ program
Sizeof int = 4	Sizeof int = 4
Sizeof char = 1	Sizeof char = 1
Sizeof ch = 1	Sizeof ch = 1
Sizeof CH = 4	Sizeof CH = 1
Sizeof wchar_t = 2	Sizeof wchar_t = 2

Constant Expressions (see page 670)

3.1.3.5.2.1.1.2 Escape Sequences

The backslash character (\) is used to introduce an escape sequence, which allows the visual representation of certain nongraphic characters. For example, the constant **\n** is used to the single newline character.

A backslash is used with octal or hexadecimal numbers to represent the ASCII symbol or control code corresponding to that value; for example, '\03' for Ctrl-C or '\x3F' for the question mark. You can use any string of up to three octal or any number of hexadecimal numbers in an escape sequence, provided that the value is within legal range for data type **char** (0 to 0xff). Larger numbers generate the compiler error Numeric constant too large. For example, the octal number \777 is larger than the maximum value allowed (\377) and will generate an error. The first nonoctal or nonhexadecimal character encountered in an octal or hexadecimal escape sequence marks the end of the sequence.

Take this example.

```
printf("\x0072.1A Simple Operating System");
```

This is intended to be interpreted as \x007 and "2.1A Simple Operating System". However, the compiler treats it as the hexadecimal number \x0072 and the literal string "2.1A Simple Operating System".

To avoid such problems, rewrite your code like this:

```
printf("\x007" "2.1A Simple Operating System");
```

Ambiguities might also arise if an octal escape sequence is followed by a nonoctal digit. For example, because 8 and 9 are not legal octal digits, the constant \258 would be interpreted as a two-character constant made up of the characters \25 and 8.

The following table shows the available escape sequences.

Escape sequences

Note: You must use \\ to represent an ASCII backslash, as used in operating system paths.

Sequence	Value	Char	What it does
\a	0x07	BEL	Audible bell
\b	0x08	BS	Backspace
\f	0x0C	FF	Formfeed
\n	0x0A	LF	Newline (linefeed)
\r	0x0D	CR	Carriage return
\t	0x09	HT	Tab (horizontal)
\v	0x0B	VT	Vertical tab
\\	0x5c	\	Backslash
\'	0x27	'	Single quote (apostrophe)
\"	0x22	"	Double quote
\?	0x3F	?	Question mark
\O		any	O=a string of up to three octal digits
\xH		any	H=a string of hex digits
\XH		any	H=a string of hex digits

3.1.3.5.2.1.1.3 The Three Char Types

One-character constants, such as 'A', '\t' and '007', are represented as **int** values. In this case, the low-order byte is sign extended into the high bit; that is, if the value is greater than 127 (base 10), the upper bit is set to -1 (=0xFF). This can be disabled by declaring that the default **char** type is **unsigned.**

The three character types, **char**, **signed char**, and **unsigned char,** require an 8-bit (one byte) storage. By default, the compiler treats character declarations as signed. Use the –K compiler option to treat character declarations as unsigned. The behavior of C programs is unaffected by the distinction between the three character types.

In a C++ program, a function can be overloaded with arguments of type **char**, **signed char**, or **unsigned char**. For example, the following function prototypes are valid and distinct:

```
void func(char ch);
void func(signed char ch);
void func(unsigned char ch);
```

If only one of the above prototypes exists, it will accept any of the three character types. For example, the following is acceptable:

```
void func(unsigned char ch);
void main(void)
{
  signed char ch = 'x';
  func(ch);
}
```

3.1.3.5.2.1.1.4 Wide-character And Multi-character Constants

Wide-character types can be used to represent a character that does not fit into the storage space allocated for a **char** type. A wide character is stored in a two-byte space. A character constant preceded immediately by an L is a wide-character constant of data type wchar_t (defined in stddef.h). For example:

```
wchar_t ch = L'A';
```

When wchar_t is used in a C program it is a type defined in stddef.h header file. In a C++ program, **wchar_t** is a keyword that can represent distinct codes for any element of the largest extended character set in any of the supported locales. In CodeGear C++, **wchar_t** is the same size, signedness, and alignment requirement as an unsigned short type.

A string preceded immediately by an L is a wide-character string. The memory allocation for a string is two bytes per character. For example:

```
wchar_t *str = L"ABCD";
```

Multi-character constants

The compiler also supports multi-character constants. Multi-character constants can consist of as many as four characters. For example, the constant, '\006\007\008\009' is valid only in a CodeGear C++ program. Multi-character constants are always 32-bit **int** values. The constants are not portable to other C++ compilers.

This section contains Constant Expression topics.

Topics

Name	Description
Constant Expressions (see page 670)	A constant expression is an expression that always evaluates to a constant (it is evaluated at compile-time and it must evaluate to a constant that is in the range of representable values for its type). Constant expressions are evaluated just as regular expressions are. You can use a constant expression anywhere that a constant is legal. The syntax for constant expressions is:

3.1.3.5.2.1.4.1 Constant Expressions

A constant expression is an expression that always evaluates to a constant (it is evaluated at compile-time and it must evaluate to a constant that is in the range of representable values for its type). Constant expressions are evaluated just as regular expressions are. You can use a constant expression anywhere that a constant is legal. The syntax for constant expressions is:

```
constant-expression:
Conditional-expression
```

Constant expressions cannot contain any of the following operators, unless the operators are contained within the operand of a **sizeof** operator:

- Assignment
- Comma
- Decrement
- Function call
- Increment

3.1.3.5.2.1.5 Constants and Internal Representation

This section contains Constants and Internal Representation topics.

Topics

Name	Description
Constants And Internal Representation (see page 671)	ANSI C acknowledges that the size and numeric range of the basic data types (and their various permutations) are implementation-specific and usually derive from the architecture of the host computer. For CodeGear C++, the target platform is the IBM PC family (and compatibles), so the architecture of the Intel 80x86 and the Pentium family of microprocessors governs the choices of internal representations for the various data types. The following tables list the sizes and resulting ranges of the data types. Internal representation of numerical types shows how these types are represented internally. **32-bit data types, sizes, and ranges**

3.1.3.5.2.1.5.1 Constants And Internal Representation

ANSI C acknowledges that the size and numeric range of the basic data types (and their various permutations) are implementation-specific and usually derive from the architecture of the host computer. For CodeGear C++, the target platform is the IBM PC family (and compatibles), so the architecture of the Intel 80x86 and the Pentium family of microprocessors governs the choices of internal representations for the various data types.

The following tables list the sizes and resulting ranges of the data types. Internal representation of numerical types shows how these types are represented internally.

32-bit data types, sizes, and ranges

Type	Size (bits)	Range	Sample applications
unsigned char	8	0 <= X <= 255	Small numbers and full PC character set
char	8	-128 <= X <= 127	Very small numbers and ASCII characters
short int	16	-32,768 <= X <= 32,767	Counting, small numbers, loop control
unsigned int	32	0 <= X <= 4,294,967,295	Large numbers and loops
int	32	-2,147,483,648 <= X <= 2,147,483,647	Counting, small numbers, loop control
unsigned long	32	0 <= X <= 4,294,967,295	Astronomical distances
enum	32	-2,147,483,648 <= X <= 2,147,483,647	Ordered sets of values
long	32	-2,147,483,648 <= X <= 2,147,483,647	Large numbers, populations
float	32	1.18 (10^-38 < |X| < 3.40 (10^38	Scientific (7-digit) precision)
double	64	2.23 (10^-308 < |X| < 1.79 (10^308	Scientific (15-digit precision)
long double	80	3.37 (10^-4932 < |X| < 1.18 (10^4932	Financial (18-digit precision)

Internal Representation Of Numerical Types (see page 676)

3.1.3.5.2.1.6 Floating Point Constants

A floating-point constant consists of:

- Decimal integer
- Decimal point
- Decimal fraction
- e or E and a signed integer exponent (optional)
- Type suffix: f or F or l or L (optional)

You can omit either the decimal integer or the decimal fraction (but not both). You can omit either the decimal point or the letter e (or E) and the signed integer exponent (but not both). These rules allow for conventional and scientific (exponent) notations.

Negative floating constants are taken as positive constants with the unary operator minus (-) prefixed.

Here are some examples:

Constant	Value
23.45e6	23.45 (10^6
.0	0
0.	0.0
1.	1.0
-1.23	-1.23
2e-5	2.0 (10^-5
3E+10	3.0 (10^10
.09E34	0.09 (10^34

In the absence of any suffixes, floating-point constants are of type **double.** However, you can coerce a floating constant to be of type **float** by adding an f or F suffix to the constant. Similarly, the suffix l or L forces the constant to be data type **long double**. The table below shows the ranges available for **float**, **double**, and **long double**.

Floating-point constant sizes and ranges

Type	Size (bits)	Range
float	32	3.4 (10^-38 to 3.4 (10^38
double	64	1.7 (10^-308 to 1.7 (10^308
long double	80	3.4 (10^-4932 to 1.1 (10^4932

3.1.3.5.2.1.7 Enumeration Constants

This section contains Enumeration Constant topics.

Topics

Name	Description
Enumeration Constants (see page 673)	Enumeration constants are identifiers defined in **enum** type declarations. The identifiers are usually chosen as mnemonics to assist legibility. Enumeration constants are integer data types. They can be used in any expression where integer constants are valid. The identifiers used must be unique within the scope of the **enum** declaration. Negative initializers are allowed. See Enumerations and enum (keyword) for a detailed look at **enum** declarations. The values acquired by enumeration constants depend on the format of the enumeration declaration and the presence of optional initializers. In this example,

3.1.3.5.2.1.7.1 Enumeration Constants

Enumeration constants are identifiers defined in **enum** type declarations. The identifiers are usually chosen as mnemonics to assist legibility. Enumeration constants are integer data types. They can be used in any expression where integer constants are valid. The identifiers used must be unique within the scope of the **enum** declaration. Negative initializers are allowed. See Enumerations and enum (keyword) for a detailed look at **enum** declarations.

The values acquired by enumeration constants depend on the format of the enumeration declaration and the presence of optional initializers. In this example,

```
enum team { giants, cubs, dodgers };
```

giants, cubs, and dodgers are enumeration constants of type team that can be assigned to any variables of type team or to any other variable of integer type. The values acquired by the enumeration constants are

```
giants = 0, cubs = 1, dodgers = 2
```

in the absence of explicit initializers. In the following example,

```
enum team { giants, cubs=3, dodgers = giants + 1 };
```

the constants are set as follows:

```
giants = 0, cubs = 3, dodgers = 1
```

The constant values need not be unique:

```
enum team { giants, cubs = 1, dodgers = cubs - 1 };
```

3.1.3.5.2.1.8 Integer Constants

Integer constants can be decimal (base 10), octal (base 8) or hexadecimal (base 16). In the absence of any overriding suffixes, the data type of an integer constant is derived from its value, as shown in Integer constants without L or U.. Note that the rules vary between decimal and nondecimal constants.

Decimal

Decimal constants from 0 to 4,294,967,295 are allowed. Constants exceeding this limit are truncated. Decimal constants must not use an initial zero. An integer constant that has an initial zero is interpreted as an octal constant. Thus,

```
int i = 10;  /*decimal 10 */
int i = 010; /*decimal 8 */
int i = 0;   /*decimal 0 = octal 0 */
```

Octal

All constants with an initial zero are taken to be octal. If an octal constant contains the illegal digits 8 or 9, an error is reported. Octal constants exceeding 037777777777 are truncated.

Hexadecimal

All constants starting with 0x (or 0X) are taken to be hexadecimal. Hexadecimal constants exceeding 0xFFFFFFFF are truncated.

long and unsigned suffixes

The suffix L (or l) attached to any constant forces the constant to be represented as a **long**. Similarly, the suffix U (or u) forces the constant to be **unsigned**. It is **unsigned long** if the value of the number itself is greater than decimal 65,535, regardless of

which base is used. You can use both L and U suffixes on the same constant in any order or case: ul, lu, UL, and so on.

The data type of a constant in the absence of any suffix (U, u, L, or l) is the first of the following types that can accommodate its value:

Decimal	**int, long int, unsigned long int**
Octal	**int, unsigned int, long int, unsigned long int**
Hexadecimal	**int, unsigned int, long int, unsigned long int**

If the constant has a U or u suffix, its data type will be the first of **unsigned int, unsigned long int** that can accommodate its value.

If the constant has an L or l suffix, its data type will be the first of **long int, unsigned long int** that can accommodate its value.

If the constant has both u and l suffixes, (ul, lu, Ul, lU, uL, Lu, LU or UL), its data type will be **unsigned long int**.

Integer constants without L or U summarizes the representations of integer constants in all three bases. The data types indicated assume no overriding L or U suffix has been used.

3.1.3.5.2.1.10 String Constants

This section contains String Constant topics.

Topics

Name	Description
String Constants (see page 677)	String constants, also known as string literals, form a special category of constants used to handle fixed sequences of characters. A string literal is of data type array-of- **const char** and storage class **static**, written as a sequence of any number of characters surrounded by double quotes:

3.1.3.5.2.1.10.1 String Constants

String constants, also known as string literals, form a special category of constants used to handle fixed sequences of characters. A string literal is of data type array-of- **const char** and storage class **static**, written as a sequence of any number of characters surrounded by double quotes:

```
"This is literally a string!"
```

The null (empty) string is written "".

The characters inside the double quotes can include escape sequences. This code, for example:

```
"\t\t\"Name\"\\\tAddress\n\n"
```

prints like this:

```
"Name"\        Address
```

"Name" is preceded by two tabs; Address is preceded by one tab. The line is followed by two new lines. The \" provides interior double quotes.

If you compile with the -**A** option for ANSI compatibility, the escape character sequence "\\", is translated to "\" by the compiler.

A literal string is stored internally as the given sequence of characters plus a final null character ('\0'). A null string is stored as a single '\0' character.

Adjacent string literals separated only by whitespace are concatenated during the parsing phase. In the following example,

```
#include <stdio.h>
```

```
int main() {
   char    *p;
   p = "This is an example of how the compiler "   " will\nconcatenate very long strings for
you"   " automatically, \nresulting in nicer" " looking programs.";
   printf(p);
   return(0);
}
```

The output of the program is

```
This is an example of how the compiler will
concatenate very long strings for you automatically,
resulting in nicer looking programs.
```

You can also use the backslash (\) as a continuation character to extend a string constant across line boundaries:

```
puts("This is really \
a one-line string");
```

3.1.3.5.2.2 Tokens

Tokens are word-like units recognized by a language. The compiler recognizes six classes of tokens.

Here is the formal definition of a token:

- keyword
- identifier
- constant
- string-literal
- operator
- punctuator (also known as separators)

As the source code is scanned, tokens are extracted in such a way that the longest possible token from the character sequence is selected. For example, external would be parsed as a single identifier, rather than as the keyword **extern** followed by the identifier al.

See Token Pasting with ## for a description of token pasting.

Lexical Elements (see page 661)

Whitespace (see page 686)

3.1.3.5.2.3 Identifiers Overview

This section contains Identifier topics.

Topics

Name	Description
Identifiers (see page 679)	Here is the formal definition of an identifier: identifier: • nondigit • identifier nondigit • identifier digit nondigit: one of • a b c d e f g h i j k l m n o p q r s t u v w x y z _ • A B C D E F G H I J K L M N O P Q R S T U V W X Y Z digit: one of • 0 1 2 3 4 • ef5 6 7 8 9 **Naming and length restrictions** Identifiers are arbitrary names of any length given to classes, objects, functions, variables,... more (see page 679)

3.1.3.5.2.3.1 Identifiers

Here is the formal definition of an identifier:

identifier:

- nondigit
- identifier nondigit
- identifier digit

nondigit: one of

- a b c d e f g h i j k l m n o p q r s t u v w x y z _
- A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

digit: one of

- 0 1 2 3 4
- ef5 6 7 8 9

Naming and length restrictions

Identifiers are arbitrary names of any length given to classes, objects, functions, variables, user-defined data types, and so on. (Identifiers can contain the letters a to z and A to Z, the underscore character "_", and the digits 0 to 9.) There are only two restrictions:

- The first character must be a letter or an underscore.

- By default, the compiler recognizes only the first 250 characters as significant. The number of significant characters can be reduced by menu and command-line options, but not increased. To change the significant character length, use the spin control in Project|Options|Advanced Compiler|Source|Identifier Length.

Case sensitivity

Identifiers in C and C++ are case sensitive, so that Sum, sum and suM are distinct identifiers.

Global identifiers imported from other modules follow the same naming and significance rules as normal identifiers. However, you have the option of suspending case sensitivity to allow compatibility when linking with case-insensitive languages. With the case-insensitive option, the globals Sum and sum are considered identical, resulting in a possible. "Duplicate symbol" warning during linking.

An exception to these rules is that identifiers of type __**pascal** are always converted to all uppercase for linking purposes.

Uniqueness and scope

Although identifier names are arbitrary (within the rules stated), errors result if the same name is used for more than one identifier within the same scope and sharing the same name space. Duplicate names are legal for different name spaces regardless of scope rules.

3.1.3.5.2.4 Keywords Overview

This section contains Keyword topics.

Topics

Name	Description
Keywords (see page 680)	Keywords are words reserved for special purposes and must not be used as normal identifier names. If you use non-ANSI keywords in a program and you want the program to be ANSI compliant, always use the non-ANSI keyword versions that are prefixed with double underscores. Some keywords have a version prefixed with only one underscore; these keywords are provided to facilitate porting code developed with other compilers. For ANSI-specified keywords there is only one version. **Note:** Note that the keywords __try and **try** are an exception to the discussion above. The keyword **try** is required to match the **catch** keyword... more (see page 680)
Keyword Extensions (see page 681)	CodeGear C++Builder provides a number of keywords that are not part of the ANSI Standard. Please see the Help table of contents for a complete categorical and alphabetical listing of Library Routines.
C++-Specific Keywords (see page 681)	A number of keywords are specific to C++ and are not available if you are writing a program in C only. Please see the Help table of contents for a complete categorical and alphabetical listing of these and other keywords.
Table Of CodeGear C++ Register Pseudovariables (see page 681)	This table lists all pseudovariables.

3.1.3.5.2.4.1 Keywords

Keywords are words reserved for special purposes and must not be used as normal identifier names.

If you use non-ANSI keywords in a program and you want the program to be ANSI compliant, always use the non-ANSI keyword versions that are prefixed with double underscores. Some keywords have a version prefixed with only one underscore; these keywords are provided to facilitate porting code developed with other compilers. For ANSI-specified keywords there is only one version.

Note: Note that the keywords __try

and **try** are an exception to the discussion above. The keyword **try** is required to match the **catch** keyword in the C++ exception-handling mechanism. **try** cannot be substituted by __**try.** The keyword __**try** can only be used to match the __**except** or __**finally** keywords. See the discussions on C++ exception handling and C-based structured exceptions under Win32 for more information. Please see the Help table of contents for a complete categorical and alphabetical listing of keywords.

See Also

Alphabetical Listing of Keywords (see page 513)

Keywords By Category (see page 579)

3.1.3.5.2.4.2 Keyword Extensions

CodeGear C++Builder provides a number of keywords that are not part of the ANSI Standard.

Please see the Help table of contents for a complete categorical and alphabetical listing of Library Routines.

See Also

C++Builder Keyword Extensions (see page 580)

Keywords (see page 513)

Keywords By Category (see page 579)

3.1.3.5.2.4.3 C++-Specific Keywords

A number of keywords are specific to C++ and are not available if you are writing a program in C only. Please see the Help table of contents for a complete categorical and alphabetical listing of these and other keywords.

3.1.3.5.2.4.4 Table Of CodeGear C++ Register Pseudovariables

This table lists all pseudovariables.

_AH	**_CL**	**_EAX**	**_ESP**
_AL	**_CS**	**_EBP**	**_FLAGS**
_AX	**_CX**	**_EBX**	**_FS**
_BH	**_DH**	**_ECX**	**_GS**
_BL	**_DI**	**_EDI**	**_SI**
_BP	**_DL**	**_EDX**	**_SP**
_BX	**_DS**	**_ES**	**_SS**
_CH	**_DX**	**_ESI**	

All but the _FLAGS and _EFLAGS register pseudovariables are associated with the general purpose, segment, address, and special purpose registers.

Use register pseudovariables anywhere that you can use an integer variable to directly access the corresponding 80x86 register.

The flags registers contain information about the state of the 80x86 and the results of recent instructions.

3.1.3.5.2.5 Punctuators Overview

This section contains Punctuator topics.

Topics

Name	Description
Punctuators (see page 682)	The C++ punctuators (also known as separators) are: • [ ] • ( ) • { } • , • ; • : • ... • = • # Most of these punctuators also function as operators. **Brackets** Open and close brackets indicate single and multidimensional array subscripts:

3.1.3.5.2.5.1 Punctuators

The C++ punctuators (also known as separators) are:

- [ ]
- ( )
- { }
- ,
- ;
- :
- ...
- =
- #

Most of these punctuators also function as operators.

Brackets

Open and close brackets indicate single and multidimensional array subscripts:

```
char ch, str[] = "Stan";
int mat[3][4];           /* 3 x 4 matrix */
ch = str[3];             /* 4th element */
  .
  .
  .
```

Parentheses

Open and close parentheses **( )** are used to group expressions, isolate conditional expressions, and indicate function calls and function parameters:

```
d = c * (a + b);/* override normal precedence */
if (d == z) ++x;/* essential with conditional statement */
```

```
func();/* function call, no args */
int (*fptr)();/* function pointer declaration */
fptr = func;/* no () means func pointer */
void func2(int n);/* function declaration with parameters */
```

Parentheses are recommended in macro definitions to avoid potential precedence problems during expansion:

```
#define CUBE(x) ((x) * (x) * (x))
```

The use of parentheses to alter the normal operator precedence and associativity rules is covered in Expressions.

Braces

Open and close braces **{ }** indicate the start and end of a compound statement:

```
if (d == z)
{
   ++x;
   func();
}
```

The closing brace serves as a terminator for the compound statement, so a ; (semicolon) is not required after the }, except in structure or class declarations. Often, the semicolon is illegal, as in

```
if (statement)
   {};                  /* illegal semicolon */
else
```

Comma

The comma (**,**) separates the elements of a function argument list:

```
void func(int n, float f, char ch);
```

The comma is also used as an operator in comma expressions. Mixing the two uses of comma is legal, but you must use parentheses to distinguish them. Note that (exp1, exp2) evaluates both but is equal to the second:

```
func(i, j);                              /* call func with two args */
func((exp1, exp2), (exp3, exp4, exp5));  /* also calls func with two args! */
```

Semicolon

The semicolon (**;**) is a statement terminator. Any legal C or C++ expression (including the empty expression) followed by a semicolon is interpreted as a statement, known as an expression statement. The expression is evaluated and its value is discarded. If the expression statement has no side effects, the compiler might ignore it.

```
a + b;    /* maybe evaluate a + b, but discard value */
++a;      /* side effect on a, but discard value of ++a */
;         /* empty expression = null statement */
```

Semicolons are often used to create an empty statement:

```
for (i = 0; i < n; i++)
{
   ;
}
```

Colon

Use the colon (**:**) to indicate a labeled statement:

```
start:    x=0;
...
goto start;
```

Labels are discussed in Labeled statements.

Ellipsis

The ellipsis

(**...**) is three successive periods with no intervening whitespace. Ellipses are used in the formal argument lists of function prototypes to indicate a variable number of arguments, or arguments with varying types:

```
void func(int n, char ch,...);
```

This declaration indicates that func will be defined in such a way that calls must have at least two arguments, an **int** and a **char**, but can also have any number of additional arguments.

In C++, you can omit the comma before the ellipsis.

Asterisk (pointer declaration)

The asterisk (*****) in a variable declaration denotes the creation of a pointer to a type:

```
char *char_ptr;  /* a pointer to char is declared */
```

Pointers with multiple levels of indirection can be declared by indicating a pertinent number of asterisks:

```
int **int_ptr;         /* a pointer to an integer array */
double ***double_ptr;  /* a pointer to a matrix of doubles */
```

You can also use the asterisk as an operator to either dereference a pointer or as the multiplication operator:

```
i = *int_ptr;
a = b * 3.14;
```

Equal sign (initializer)

The equal sign (**=**) separates variable declarations from initialization lists:

```
char array[5] = { 1, 2, 3, 4, 5 };
int  x = 5;
```

In C++, declarations of any type can appear (with some restrictions) at any point within the code. In a C function, no code can precede any variable declarations.

In a C++ function argument list, the equal sign indicates the default value for a parameter:

```
int f(int i = 0) { ... }  /* Parameter i has default value of zero */
```

The equal sign is also used as the assignment operator in expressions:

```
int a, b, c;
a = b + c;
float *ptr = (float *) malloc(sizeof(float) * 100);
```

Pound sign (preprocessor directive)

The pound sign (#) indicates a preprocessor directive when it occurs as the first nonwhitespace character on a line. It signifies a compiler action, not necessarily associated with code generation. See Preprocessor directives for more on the preprocessor directives.

and ## (double pound signs) are also used as operators to perform token replacement and merging during the preprocessor scanning phase. See Token pasting.

3.1.3.5.3 Whitespace Overview

This section contains Whitespace Overview topics.

Topics

Name	Description
Comments (see page 685)	Comments are pieces of text used to annotate a program. Comments are for the programmer's use only; they are stripped from the source text before parsing. There are two ways to delineate comments: the C method and the C++ method. The compiler supports both methods, and provides an additional, optional extension permitting nested comments. If you are not compiling for ANSI compatibility, you can use any of these kinds of comments in both C and C++ programs. You should also follow the guidelines on the use of whitespace and delimiters in comments discussed later in this topic to avoid other... more (see page 685)
Whitespace (see page 686)	Whitespace is the collective name given to spaces (blanks), horizontal and vertical tabs, newline characters, and comments. Whitespace can serve to indicate where tokens start and end, but beyond this function, any surplus whitespace is discarded. For example, the two sequences

3.1.3.5.3.1 Comments

Comments are pieces of text used to annotate a program. Comments are for the programmer's use only; they are stripped from the source text before parsing.

There are two ways to delineate comments: the C method and the C++ method. The compiler supports both methods, and provides an additional, optional extension permitting nested comments. If you are not compiling for ANSI compatibility, you can use any of these kinds of comments in both C and C++ programs.

You should also follow the guidelines on the use of whitespace and delimiters in comments discussed later in this topic to avoid other portability problems.

C comments

A C comment is any sequence of characters placed after the symbol pair /*. The comment terminates at the first occurrence of the pair ***/** following the initial /*. The entire sequence, including the four comment-delimiter symbols, is replaced by one space after macro expansion. Note that some C implementations remove comments without space replacements.

The compiler does not support the nonportable token pasting strategy using /**/. Token pasting is performed with the ANSI-specified pair ##, as follows:

```
#define VAR(i,j)  (i/**/j)    /* won't work */
#define VAR(i,j)  (i##j)      /* OK */
#define VAR(i,j)  (i ## j)    /* Also OK */
```

The compiler parses the declaration,

```
int /* declaration */ i /* counter */;
```

as these three tokens:

```
int   i;
```

See Token Pasting with ## for a description of token pasting.

C++ comments

C++ allows a single-line comment using two adjacent slashes (//). The comment can start in any position, and extends until the next new line:

```
class X {  // this is a comment
... };
```

You can also use // to create comments in C code. This feature is specific to the CodeGear C++ compiler and is generally not portable.

Nested comments

ANSI C doesn't allow nested comments. The attempt to comment out a line

```
/*  int /* declaration */ i /* counter */; */
```

fails, because the scope of the first **/*** ends at the first */. This gives

```
i ; */
```

which would generate a syntax error.

To allow nested comments, check Project|Options|Advanced Compiler|Source|Nested Comments.

Delimiters and whitespace

In rare cases, some whitespace before /* and //, and after */, although not syntactically mandatory, can avoid portability problems. For example, this C++ code:

```
int i = j//* divide by k*/k;
+m;
```

parses as int i = j +m; not as

```
int i = j/k;
+m;
```

as expected under the C convention. The more legible

```
int i = j/ /* divide by k*/ k;
+m;
```

avoids this problem.

See Also

Lexical Elements (see page 661)

Whitespace (see page 686)

Tokens (see page 678)

3.1.3.5.3.2 Whitespace

Whitespace is the collective name given to spaces (blanks), horizontal and vertical tabs, newline characters, and comments. Whitespace can serve to indicate where tokens start and end, but beyond this function, any surplus whitespace is discarded. For example, the two sequences

```
int i; float f;
```

and

```
int i;
   float f;
```

are lexically equivalent and parse identically to give the six tokens:

- **int**
- i
- **;**
- **float**
- **f**
- **;**

The ASCII characters representing whitespace can occur within literal strings, in which case they are protected from the normal parsing process (they remain as part of the string). For example,

```
char name[] = "CodeGear Corporation";
```

parses to seven tokens, including the single literal-string token "CodeGear Corporation"

**Line splicing with **

A special case occurs if the final newline character encountered is preceded by a backslash (\). The backslash and new line are both discarded, allowing two physical lines of text to be treated as one unit.

```
"CodeGear \
Corporation"
```

is parsed as "CodeGear Corporationl" (see String constants for more information).

3.1.3.6.1 Conditional Compilation Overview

This section contains Conditional Compilation Overview topics.

Topics

Name	Description
Conditional Compilation (see page 687)	The compiler supports conditional compilation by replacing the appropriate source-code lines with a blank line. The lines thus ignored are those beginning with # (except the **#if**, **#ifdef**, **#ifndef**, **#else**, **#elif**, and **#endif** directives), as well as any lines that are not to be compiled as a result of the directives. All conditional compilation directives must be completed in the source or include file in which they are begun.
#if, #elif, #else, And #endif (see page 688)	**Syntax**
#ifdef And #ifndef (see page 688)	**Syntax**
Defined (see page 689)	**Syntax**

3.1.3.6.1.1 Conditional Compilation

The compiler supports conditional compilation by replacing the appropriate source-code lines with a blank line. The lines thus ignored are those beginning with # (except the **#if**, **#ifdef**, **#ifndef**, **#else**, **#elif**, and **#endif** directives), as well as any lines that are not to be compiled as a result of the directives. All conditional compilation directives must be completed in the source or include file in which they are begun.

3.1.3.6.1.2 #if, #elif, #else, And #endif

Syntax

```
#if constant-expression-1
<section-1>
<#elif constant-expression-2 newline section-2>
  .
  .
  .
<#elif constant-expression-n newline section-n>
<#else <newline> final-section>
#endif
```

Description

The compiler supports conditional compilation by replacing the appropriate source-code lines with a blank line. The lines thus ignored are those lines that are not to be compiled as a result of the directives. All conditional compilation directives must be completed in the source or include file in which they are begun.

The conditional directives **#if**, **#elif**, **#else**, and **#endif** work like the normal C conditional operators. If the constant-expression-1 (subject to macro expansion) evaluates to nonzero (true), the lines of code (possibly empty) represented by section-1, whether preprocessor command lines or normal source lines, are preprocessed and, as appropriate, passed to the compiler. Otherwise, if constant-expression-1 evaluates to zero (false), section-1 is ignored (no macro expansion and no compilation).

In the true case, after section-1 has been preprocessed, control passes to the matching **#endif** (which ends this conditional sequence) and continues with next-section. In the false case, control passes to the next **#elif** line (if any) where constant-expression-2 is evaluated. If true, section-2 is processed, after which control moves on to the matching **#endif**. Otherwise, if constant-expression-2 is false, control passes to the next **#elif**, and so on, until either **#else** or **#endif** is reached. The optional **#else** is used as an alternative condition for which all previous tests have proved false. The **#endif** ends the conditional sequence.

The processed section can contain further conditional clauses, nested to any depth; each **#if** must be matched with a closing **#endif**.

The net result of the preceding scenario is that only one section (possibly empty) is passed on for further processing. The bypassed sections are relevant only for keeping track of any nested conditionals, so that each **#if** can be matched with its correct **#endif**.

The constant expressions to be tested must evaluate to a constant integral value.

See Also

defined (see page 689)

#ifdef And #ifndef (see page 688)

3.1.3.6.1.3 #ifdef And #ifndef

Syntax

```
#ifdef identifier
#ifndef identifier
```

Description

The **#ifdef** and **#ifndef** conditional directives let you test whether an identifier is currently defined or not; that is, whether a previous **#define** command has been processed for that identifier and is still in force. The line

```
#ifdef identifier
```

has exactly the same effect as

```
#if 1
```

if identifier is currently defined, and the same effect as

```
#if 0
```

if identifier is currently undefined.

#ifndef tests true for the "not-defined" condition, so the line

```
#ifndef identifier
```

has exactly the same effect as

```
#if 0
```

if identifier is currently defined, and the same effect as

```
#if 1
```

if identifier is currently undefined.

The syntax thereafter follows that of the **#if**, **#elif**, **#else**, and **#endif**.

An identifier defined as NULL is considered to be defined.

3.1.3.6.1.4 Defined

Syntax

```
#if defined[(] <identifier> [)]
#elif defined[(] <identifier> [)]
```

Description

Use the **defined** operator to test if an identifier was previously defined using **#define**. The **defined** operator is only valid in **#if** and **#elif** expressions.

Defined evaluates to 1 (true) if a previously defined symbol has not been undefined (using **#undef**); otherwise, it evaluates to 0 (false).

Defined performs the same function as **#ifdef**.

```
#if defined(mysym)
```

is the same as

```
#ifdef mysym
```

The advantage is that you can use defined repeatedly in a complex expression following the **#if** directive; for example,

```
#if defined(mysym) && !defined(yoursym)
```

3.1.3.6.2 Defining And Undefining Macros

This section contains Defining And Undefining Macro topics.

Topics

Name	Description
Using The -D And -U Command-line Options (see page 690)	Identifiers can be defined and undefined using the command-line compiler options -D and -U. The command line
Keywords And Protected Words In Macros (see page 690)	It is legal but ill-advised to use C++ keywords as macro identifiers:
#define (see page 690)	**Syntax**
#undef (see page 691)	**Syntax**

3.1.3.6.2.1 Using The -D And -U Command-line Options

Identifiers can be defined and undefined using the command-line compiler options -D and -U.

The command line

```
BCC32 -Ddebug=1; paradox=0; X -Umysym myprog.cbc++ -Ddebug=1:paradox=0:X -Umysym myprog.c
bc++ -Ddebug=1:paradox=0:X -Umysym myprog.c
```

is equivalent to placing

```
#define debug 1
#define paradox 0
```

in the program.

See Also

#define (see page 690)

3.1.3.6.2.2 Keywords And Protected Words In Macros

It is legal but ill-advised to use C++ keywords as macro identifiers:

```
#define int long    /* legal but probably catastrophic */
#define INT long    /* legal and possibly useful */
```

The following predefined global identifiers cannot appear immediately following a **#define** or **#undef** directive:

- **__DATE__ __FILE__ __LINE__**
- **__STDC__ __TIME__**

3.1.3.6.2.3 #define

Syntax

```
#define macro_identifier <token_sequence>
```

Description

The **#define** directive defines a macro. Macros provide a mechanism for token replacement with or without a set of formal, function-like parameters.

Each occurrence of **macro_identifier** in your source code following this control line will be replaced in the original position with the possibly empty **token_sequence** (there are some exceptions, which are noted later). Such replacements are known as macro expansions. The token sequence is sometimes called the body of the macro.

An empty token sequence results in the removal of each affected macro identifier from the source code.

After each individual macro expansion, a further scan is made of the newly expanded text. This allows for the possibility of nested macros: The expanded text can contain macro identifiers that are subject to replacement. However, if the macro expands into what looks like a preprocessing directive, the directive will not be recognized by the preprocessor. There are these

restrictions to macro expansion:

- Any occurrences of the macro identifier found within literal strings, character constants, or comments in the source code are not expanded.
- A macro won't be expanded during its own expansion (so **#define** A A won't expand indefinitely).

Example

```
#define HI "Have a nice day!"
#define empty
```

Keywords And Protected Words In Macros (see page 690)

Macros With Parameters (see page 694)

#undef (see page 691)

Using The -D And -U Command-line Options (see page 690)

3.1.3.6.2.4 #undef

Syntax

```
#undef macro_identifier
```

Description

You can undefine a macro using the **#undef** directive. **#undef** detaches any previous token sequence from the macro identifier; the macro definition has been forgotten, and the macro identifier is undefined. No macro expansion occurs within **#undef** lines.

The state of being defined or undefined turns out to be an important property of an identifier, regardless of the actual definition. The **#ifdef** and **#ifndef** conditional directives, used to test whether any identifier is currently defined or not, offer a flexible mechanism for controlling many aspects of a compilation.

After a macro identifier has been undefined, it can be redefined with **#define**, using the same or a different token sequence.

Attempting to redefine an already defined macro identifier will result in a warning unless the new definition is exactly the same token-by-token definition as the existing one. The preferred strategy where definitions might exist in other header files is as follows:

```
#ifndef BLOCK_SIZE
  #define BLOCK_SIZE 512
```

The middle line is bypassed if BLOCK_SIZE is currently defined; if BLOCK_SIZE is not currently defined, the middle line is invoked to define it.

No semicolon (;) is needed to terminate a preprocessor directive. Any character found in the token sequence, including semicolons, will appear in the macro expansion. The token sequence terminates at the first non-backslashed new line encountered. Any sequence of whitespace, including comments in the token sequence, is replaced with a single-space character.

#define (see page 690)

Preprocessor Directives (see page 710)

3.1.3.6.3 The #error Control Directive

This section contains #error Control Directive topics.

Topics

Name	Description
#error (see page 692)	**Syntax**

3.1.3.6.3.1 #error

Syntax

```
#error errmsg
```

Description

The **#error** directive generates the message:

```
Error: filename line# : Error directive: errmsg
```

This directive is usually embedded in a preprocessor conditional statement that catches some undesired compile-time condition. In the normal case, that condition will be false. If the condition is true, you want the compiler to print an error message and stop the compile. You do this by putting an **#error** directive within a conditional statement that is true for the undesired case.

3.1.3.6.4 File Inclusion With #include

This section contains File Inclusion With #include topics.

Topics

Name	Description
#include (see page 692)	**Syntax**
Header File Search With <header_name> (see page 693)	The <header_name> version specifies a standard include file; the search is made successively in each of the include directories in the order they are defined. If the file is not located in any of the default directories, an error message is issued.
Header File Search With "header_name" (see page 693)	The "header_name" version specifies a user-supplied include file; the file is searched in the following order: 1. The same directory of the file that contains the **#include** statement 2. The directories of files that include (**#include**) that file 3. The current directory 4. The path specified by the /I compiler option

3.1.3.6.4.1 #include

Syntax

```
#include <header_name>
#include "header_name"
#include <macro_definition>
```

Description

The **#include** directive pulls in other named files, known as include files, header files, or headers, into the source code. The syntax has three versions:

- The first and second versions imply that no macro expansion will be attempted; in other words, header_name is never scanned for macro identifiers. header_name must be a valid file name with an extension (traditionally .h for header) and optional path name and path delimiters.
- The third version assumes that neither **<** nor " appears as the first non-whitespace character following **#include**; further, it assumes a macro definition exists that will expand the macro identifier into a valid delimited header name with either of the <header_name> or "header_name" formats.

The preprocessor removes the **#include** line and conceptually replaces it with the entire text of the header file at that point in the source code. The source code itself is not changed, but the compiler "sees" the enlarged text. The placement of the **#include** can therefore influence the scope and duration of any identifiers in the included file.

If you place an explicit path in the header_name, only that directory will be searched.

The difference between the <header_name> and "header_name" formats lies in the searching algorithm employed in trying to locate the include file.

See Also

Header File Search with <header_name> (see page 693)

Header File Search with “header_name” (see page 693)

3.1.3.6.4.2 Header File Search With <header_name>

The <header_name> version specifies a standard include file; the search is made successively in each of the include directories in the order they are defined. If the file is not located in any of the default directories, an error message is issued.

See Also

Header File Search With "header_name" (see page 693)

3.1.3.6.4.3 Header File Search With "header_name"

The "header_name" version specifies a user-supplied include file; the file is searched in the following order:

1. The same directory of the file that contains the **#include** statement
2. The directories of files that include (**#include**) that file
3. The current directory
4. The path specified by the /I compiler option

See Also

Header File Search With <header_name> (see page 693)

3.1.3.6.5 The #line Control Directive

This section contains #line Control Directive topics.

Topics

Name	Description
#line (see page 693)	**Syntax**

3.1.3.6.5.1 #line

Syntax

```
#line integer_constant  <"filename">
```

Description

You can use the **#line** directive to supply line numbers to a program for cross-reference and error reporting. If your program consists of sections derived from some other program file, it is often useful to mark such sections with the line numbers of the original source rather than the normal sequential line numbers derived from the composite program.

The **#line** directive indicates that the following source line originally came from line number integer_constant of filename. Once the filename has been registered, subsequent **#line** commands relating to that file can omit the explicit filename argument.

Macros are expanded in **#line** arguments as they are in the **#include** directive.

The **#line** directive is primarily used by utilities that produce C code as output, and not in human-written code.

3.1.3.6.6 Macros With Parameters Overview

This section contains Macros With Parameters Overview topics.

Topics

Name	Description
Macros With Parameters (see page 694)	The following syntax is used to define a macro with parameters:
Nesting Parentheses And Commas (see page 695)	The actual_arg_list can contain nested parentheses provided that they are balanced; also, commas appearing within quotes or parentheses are not treated like argument delimiters.
Token Pasting With ## (see page 695)	You can paste (or merge) two tokens together by separating them with ## (plus optional whitespace on either side). The preprocessor removes the whitespace and the ##, combining the separate tokens into one new token. You can use this to construct identifiers. Given the definition
Converting To Strings With # (see page 695)	The # symbol can be placed in front of a formal macro argument in order to convert the actual argument to a string after replacement. Given the following definition:
Using The Backslash (\) For Line Continuation (see page 695)	A long token sequence can straddle a line by using a backslash (\). The backslash and the following newline are both stripped to provide the actual token sequence used in expansions.
Side Effects And Other Dangers (see page 696)	The similarities between function and macro calls often obscure their differences. A macro call has no built-in type checking, so a mismatch between formal and actual argument data types can produce bizarre, hard-to-debug results with no immediate warning. Macro calls can also give rise to unwanted side effects, especially when an actual argument is evaluated more than once. Compare CUBE and cube in the following example.

3.1.3.6.6.1 Macros With Parameters

The following syntax is used to define a macro with parameters:

```
#define macro_identifier(<arg_list>) token_sequence
```

Any comma within parentheses in an argument list is treated as part of the argument, not as an argument delimiter.

Note there can be no whitespace between the macro identifier and the **(**. The optional arg_list is a sequence of identifiers separated by commas, not unlike the argument list of a C function. Each comma-delimited identifier plays the role of a formal argument or placeholder.

Such macros are called by writing

```
macro_identifier<whitespace>(<actual_arg_list>)
```

in the subsequent source code. The syntax is identical to that of a function call; indeed, many standard library C "functions" are implemented as macros. However, there are some important semantic differences, side effects, and potential pitfalls.

The optional actual_arg_list must contain the same number of comma-delimited token sequences, known as actual arguments, as found in the formal arg_list of the **#define** line: There must be an actual argument for each formal argument. An error will be reported if the number of arguments in the two lists is different.

A macro call results in two sets of replacements. First, the macro identifier and the parenthesis-enclosed arguments are replaced by the token sequence. Next, any formal arguments occurring in the token sequence are replaced by the corresponding real arguments appearing in the actual_arg_list.

As with simple macro definitions, rescanning occurs to detect any embedded macro identifiers eligible for expansion.

See Also

Converting To Strings With # (see page 695)

Nesting Parentheses And Commas (see page 695)

Side Effects And Other Dangers (see page 696)

Using The Backslash (\) For Line Continuation (see page 695)

3.1.3.6.6.2 Nesting Parentheses And Commas

The actual_arg_list can contain nested parentheses provided that they are balanced; also, commas appearing within quotes or parentheses are not treated like argument delimiters.

```
#define ERRMSG(x, str) showerr("Error:", x. str)
#define SUM(x,y)  ((x) + (y))
:
ERRMSG(2, "Press Enter, then ESC");
/* showerr("Error",2,"Press Enter, then ESC"); */
return SUM(f(i, j), g(k, l));
/* return ( (f(i, j)) + (g(k, l)) ); */
```

3.1.3.6.6.3 Token Pasting With

You can paste (or merge) two tokens together by separating them with ## (plus optional whitespace on either side). The preprocessor removes the whitespace and the ##, combining the separate tokens into one new token. You can use this to construct identifiers.

Given the definition

```
#define VAR(i, j) (i##j)
```

the call VAR(x, 6) expands to (x6). This replaces the older nonportable method of using (i/**/j).

3.1.3.6.6.4 Converting To Strings With

The # symbol can be placed in front of a formal macro argument in order to convert the actual argument to a string after replacement.

Given the following definition:

```
#define TRACE(flag) printf(#flag "=%d\n", flag)
```

the code fragment

```
int highval = 1024;
TRACE(highval);
```

becomes

```
int highval = 1024;
printf("highval" "=%d\n", highval);
```

which, in turn, is treated as

```
int highval = 1024;
printf("highval=%d\n", highval);
```

3.1.3.6.6.5 Using The Backslash (\) For Line Continuation

A long token sequence can straddle a line by using a backslash (\). The backslash and the following newline are both stripped to provide the actual token sequence used in expansions.

```
#define WARN "This is really a single-\
line warning."
```

3.1.3.6.6.6 Side Effects And Other Dangers

The similarities between function and macro calls often obscure their differences. A macro call has no built-in type checking, so a mismatch between formal and actual argument data types can produce bizarre, hard-to-debug results with no immediate warning. Macro calls can also give rise to unwanted side effects, especially when an actual argument is evaluated more than once.

Compare CUBE and cube in the following example.

```
int cube(int x) {
   return x* x*x;
```

3.1.3.6.7 Pragma Directives Overview

This section contains Pragma Directives Overview topics.

Topics

Name	Description
#pragma (see page 696)	**Syntax**
#pragma alignment (see page 698)	**Syntax**
#pragma anon_struct (see page 698)	**Syntax**
#pragma argsused (see page 699)	**Syntax**
#pragma checkoption (see page 699)	**Syntax**
#pragma codeseg (see page 699)	**Syntax**
#pragma comment (see page 699)	**Syntax**
#pragma defineonoption and #pragma undefineonoption (see page 700)	**Syntax**
#pragma exit and #pragma startup (see page 700)	**Syntax**
#pragma hdrfile (see page 700)	**Syntax**
#pragma hdrstop (see page 701)	**Syntax**
#pragma inline (see page 701)	**Syntax**
#pragma intrinsic (see page 701)	**Syntax**
#pragma link (see page 701)	**Syntax**
#pragma message (see page 702)	**Syntax**
#pragma nopushoptwarn (see page 702)	**Syntax**
#pragma obsolete (see page 702)	**Syntax**
#pragma option (see page 703)	**Syntax**
#pragma pack (see page 704)	**Syntax**
#pragma package (see page 706)	**Syntax**
#pragma region and #pragma end_region (see page 707)	**Syntax**
#pragma resource (see page 707)	**Syntax**
#pragma warn (see page 707)	**Syntax**

3.1.3.6.7.1 #pragma

Syntax

```
#pragma directive-name
```

Description

With **#pragma**, you can set compiler directives in your source code, without interfering with other compilers that also support **#pragma**. If the compiler doesn't recognize directive-name, it ignores the **#pragma** directive without any error or warning message.

The CodeGear C++ supports the following **#pragma** directives: (Links to these topics are at the bottom of this topic.)

- **#pragma alignment**
- **#pragma anon_struct**
- **#pragma argsused**
- **#pragma checkoption**
- **#pragma codeseg**
- **#pragma comment**
- **#pragma defineonoption**
- **#pragma exit**
- **#pragma hdrfile**
- **#pragma hdrstop**
- **#pragma inline**
- **#pragma intrinsic**
- **#pragma link**
- **#pragma message**
- **#pragma nopushoptwarn**
- **#pragma obsolete**
- **#pragma option**
- **#pragma pack**
- **#pragma package**
- **#pragma region/end_region**
- **#pragma resource**
- **#pragma startup**
- **#pragma undefineonoption**
- **#pragma warn**

See Also

#pragma alignment (see page 698)

#pragma anon_struct (see page 698)

#pragma argsused (see page 699)

#pragma checkoption (see page 699)

#pragma codeseg (see page 699)

#pragma comment (see page 699)

#pragma defineonoption (see page 700)

#pragma exit (see page 700)

#pragma hdrfile (see page 700)

#pragma hdrstop (see page 701)

#pragma inline (see page 701)

#pragma intrinsic (see page 701)

#pragma link (see page 701)

#pragma message (see page 702)

#pragma nopushoptwarn (see page 702)

#pragma obsolete (see page 702)

#pragma option (see page 702)

#pragma pack (see page 704)

#pragma package (see page 706)

#pragma region/end_region (see page 707)

#pragma resource (see page 707)

#pragma startup (see page 700)

#pragma undefineonoption (see page 700)

#pragma warn (see page 707)

3.1.3.6.7.2 #pragma alignment

Syntax

```
#pragma alignment
```

Description

This pragma prints out the current byte alignment and `enum` size.

For instance, the pragma

```
#pragma alignment
```

might print out this:

The alignment is 4 bytes, the enum size is 4 bytes

3.1.3.6.7.3 #pragma anon_struct

Syntax

```
#pragma anon_struct on
#pragma anon_struct off
```

Description

The **anon_struct** directive allows you to compile anonymous structures embedded in classes.

```
#pragma anon_struct on
struct S {
   int i;
   struct {  // Embedded anonymous struct
      int   j ;
      float x ;
   };
   class {  // Embedded anonymous class
   public:
      long double ld;
   };
   S() { i = 1; j = 2; x = 3.3; ld = 12345.5;}
};
#pragma anon_struct off
```

```
void main()
{
   S mystruct;
   mystruct.x = 1.2;  // Assign to embedded data.
}
```

3.1.3.6.7.4 #pragma argsused

Syntax

```
#pragma argsused
```

Description

The **argsused** pragma is allowed only between function definitions, and it affects only the next function. It disables the warning message:

```
"Parameter name is never used in function func-name"
```

3.1.3.6.7.5 #pragma checkoption

Syntax

```
#pragma checkoption <switches>
```

where <switches> are any command line switches.

Description

This pragma checks a set of options.

For instance, the following pragma

```
#pragma checkoption -w- -Vx
```

checks if the options `-w-` and `-Vx` are active. If not, you get the error:

Error E2471 **filename**: pragma checkoption failed: options are not as expected

3.1.3.6.7.6 #pragma codeseg

Syntax

```
#pragma codeseg <seg_name> <"seg_class"> <group>
```

Description

The **codeseg** directive lets you name the segment, class, or group where functions are allocated. If the pragma is used without any of its options, the default code segment is used for function allocation.

3.1.3.6.7.7 #pragma comment

Syntax

```
#pragma comment (comment type, "string")
```

Description

The **comment** directive lets you write a comment record into an output file. The comment type can be one of the following values:

Value	Explanation
exestr	The linker writes string into an .obj file. Your specified string is placed in the executable file. Such a string is never loaded into memory but can be found in the executable file by use of a suitable file search utility.

lib	Writes a comment record into an .obj file. A library module that is not specified in the linker's response-file can be specified by the **comment** LIB directive. The linker includes the library module name specified in string as the last library. Multiple modules can be named and linked in the order in which they are named.
user	The compiler writes string into the .obj file. The linker ignores the specified string.

3.1.3.6.7.8 #pragma defineonoption and #pragma undefineonoption

Syntax

```
#pragma defineonoption <macroname>
        <switches>
#pragma undefineonoption <macroname>
        <switches>
```

where <macroname> is a name to define or undefine, and <switches> are any command line switches.

Description

The pragma `#pragma defineonoption` defines a macro name when specified options are set. The macro name is defined if *all* the switches in are turned on, either from the command line or through a pragma.

The pragma `#pragma undefineonoption` undefines a macro name when specified options are set.

For instance, the following pragma

```
#pragma defineonoption DEBUG -v
```

results in the macro `DEBUG` being defined when the option `-v` is set.

In contrast, this pragma

```
#pragma undefineonoption DEBUG -v
```

results in the macro `DEBUG` being *undefined* when the option `-v` is set.

3.1.3.6.7.9 #pragma exit and #pragma startup

Syntax

```
#pragma startup function-name <priority>
#pragma exit function-name <priority>
```

Description

These two pragmas allow the program to specify function(s) that should be called either upon program startup (before the main function is called), or program exit (just before the program terminates through _**exit**).

The specified function-name must be a previously declared function taking no arguments and returning **void**; in other words, it should be declared as:

```
void func(void);
```

The optional priority parameter should be an integer in the range 64 to 255. The highest priority is 0. Functions with higher priorities are called first at startup and last at exit. If you don't specify a priority, it defaults to 100.

Warning: Do not use priority values less than 64. Priorities from 0 to 63 are reserved for ISO startup and shutdown mechanisms.

3.1.3.6.7.10 #pragma hdrfile

Syntax

```
#pragma hdrfile "filename.csm"
```

Description

This directive sets the name of the file in which to store precompiled headers.

If you aren't using precompiled headers, this directive has no effect. You can use the command-line compiler option -H=filename or Use Precompiled Headers to change the name of the file used to store precompiled headers.

3.1.3.6.7.11 #pragma hdrstop

Syntax

```
#pragma hdrstop
```

Description

This directive terminates the list of header files eligible for precompilation. You can use it to reduce the amount of disk space used by precompiled headers.

Precompiled header files can be shared between the source files of your project only if the **#include** directives before **#pragma hdrstop** are identical. Therefore, you get the best compiler performance if you include common header files of your project before the **#pragma hdrstop**, and specific ones after it. Make sure the **#include** directives before the **#pragma hdrstop** are identical in all the source files, or that there are only very few variations.

The integrated development environment generates code to enhance precompiled header performance. For example, after a New Application, source file "Unit1.cpp" will look like this (comments added):

```
#include <clxvcl.h>       // common header file
#pragma hdrstop      // terminate list here
```

Use this pragma directive only in source files. The pragma has no effect when it is used in a header file.

3.1.3.6.7.12 #pragma inline

Syntax

```
#pragma inline
```

Description

This directive is equivalent to the -B command-line compiler option.

This is best placed at the top of the file, because the compiler restarts itself with the -B option when it encounters **#pragma inline**.

3.1.3.6.7.13 #pragma intrinsic

Syntax

```
#pragma intrinsic [-]function-name
```

Description

Use **#pragma intrinsic** to override command-line switches or project options to control the inlining of functions.

When inlining an intrinsic function, always include a prototype for that function before using it.

3.1.3.6.7.14 #pragma link

Syntax

```
#pragma link "[path]modulename[.ext]"
```

Description

The directive instructs the linker to link the file into an executable file.

By default, the linker searches for modulename in the local directory and any path specified by the **-L** option. You can use the path argument to specify a directory.

By default, the linker assumes a .obj extension.

3.1.3.6.7.15 #pragma message

Syntax

```
#pragma message ("text" ["text"["text" ...]])
#pragma message text
```

Description

Use **#pragma message** to specify a user-defined message within your program code.

The first form requires that the text consist of one or more string constants, and the message must be enclosed in parentheses. (This form is compatible with Microsoft C.) This form will output the constant contained between the double quotes regardless of whether it is a macro or not.

The second form uses the text following the **#pragma** for the text of the warning message. With this form of the **#pragma**, any macro references are expanded before the message is displayed.

The third form will output the macro-expanded value of text following the **#pragma**, if it is **#defined**. If is not **#defined**, you'll get an ill-formed pragma warning.

User-defined messages are displayed as messages, not warnings.

Display of user-defined messages is on by default and can be turned on or off with the `Show Messages` option. This option corresponds to the compiler's **-wmsg** switch.

Messages are only displayed in the IDE if **Show general messages** is checked on the **C++ Project Properties** under **Project ▸ Options ▸ Project Propertes**.

See Also

Preprocessor Directives (see page 710)

3.1.3.6.7.16 #pragma nopushoptwarn

Syntax

```
#pragma nopushoptwarn
```

Description

The **nopushoptwarn** pragma allows the use of pragma option push without pop and pragma option pop without push // in a file. Normally a warning would be given.

3.1.3.6.7.17 #pragma obsolete

Syntax

```
#pragma obsolete identifier
```

Description

Use **#pragma obsolete** to give a warning the first time the preprocessor encounters identifier in your program code after the

pragma. The warning states that the identifier is obsolete.

3.1.3.6.7.18 #pragma option

Syntax

```
#pragma option options
#pragma option push options
#pragma option pop
#pragma nopushoptwarn
```

Description

Use **#pragma option** to include command-line options within your program code. **#pragma option** can also be used with the push or pop arguments.

#pragma option [options...]

options can be any command-line option (except those listed in the following paragraph). Any number of options can appear in one directive. For example, both of the following are valid:

```
#pragma option -C
#pragma option -C -A
```

Any of the toggle options (such as **-a** or **-K**) can be turned on and off as on the command line. For these toggle options, you can also put a period following the option to return the option to its command-line, configuration file, or option-menu setting. This allows you to temporarily change an option, and then return it to its default, without having to remember (or even needing to know) what the exact default setting was.

Options that cannot appear in a **pragma option** include:

B	c	dname
Dname=string	efilename	E
Fx	h	Ifilename
lexset	M	o
P	Q	S
T	Uname	V
X	Y	

- You can use **#pragma**s, **#include**s, **#define**, and some **#if**s in the following cases:
- Before the use of any macro name that begins with two underscores (and is therefore a possible built-in macro) in an **#if**, **#ifdef**, **#ifndef** or **#elif** directive.
- Before the occurrence of the first real token (the first C or C++ declaration).

Certain command-line options can appear only in a #**pragma option** command before these events. These options are:

Efilename	f	i#
m*	npath	ofilename
U	W	z

*

Other options can be changed anywhere. The following options will only affect the compiler if they get changed between functions or object declarations:

1	h	r
2	k	rd
A	N	v
Ff	O	y
G	p	Z

The following options can be changed at any time and take effect immediately:

A	gn	zE
b	jn	zF
C	K	zH
d	wxxx	

The options can appear followed by a dot (.) to reset the option to its command-line state.

#pragma option using push or pop

The **#pragma option** directive can also be used with the push and pop arguments to enable you to easily modify compiler directives.

Using the **#pragma option push** allows you to save all (or a selected subset of) options before including any files that could potentially change many compiler options and warnings, and then, with the single statement, **#pragma option pop**, return to the previous state. For example:

```
#pragma option push
#include <theworld.h>
#pragma option pop
#include "mystuff.h"
```

The **#pragma option push** directive first pushes all compiler options and warning settings on a stack and then handles any options (if supplied). The following examples show how the **#pragma option push** can be used with or without options:

```
#pragma option push -C -A
#pragma option push
```

The **#pragma option pop** directive changes compiler options and warnings by popping the last set of options and warnings from the stack. It gives a warning, "Pragma option pop with no matching option push", if the stack is empty, in which case nothing happens.

The following generates a warning about an empty stack:

```
#pragma option push
#pragma option pop
#pragma option pop      /* Warning */
```

We do not recommend it, but you can turn off this warning with the directive: #pragma warn -nop.

If you try to specify any options after pop, you get the error, "Nothing allowed after pragma option pop." For example, the following produces an error:

```
#pragma option pop -C/* ERROR */
```

If your stack of pushed options is not the same at the start of a file as at the end of a file, you receive a warning: "Previous options and warnings not restored." To turn off this warning, use the directive, **#pragma nopushoptwarn** .

3.1.3.6.7.19 #pragma pack

Syntax

```
#pragma pack([{push | pop}[,]] [identifier[,]] [n])
```

Description

The **#pragma pack(n)**.directive is the same as using the #pragma option specifically with the -a compiler option. **n** is the byte alignment that determines how the compiler aligns data in stored memory. For more information see the -a compiler option. **#pragma pack** can also be used with **push** and **pop** arguments, which provide the same functionality as the **#pragma option** directive using **push** and **pop**. The following table compares the use of **#pragma pack** with **#pragma option**.

#pragma pack	#pragma option
#pragma pack(n)	#pragma option -an
#pragma pack(push, n)	#pragma option push -an
#pragma pack(pop)	#pragma option pop

The **#pragma pack** directive also supports an identifier argument which must be used in combination with either push or pop.

#pragma pack with no arguments

```
#pragma pack()
```

Using **#pragma pack** with no arguments will set the packing size to the starting –aX alignment (which defaults to 8). The starting -aX alignment is considered the alignment at the start of the compile AFTER all command-line options have been processed.

#pragma pack using a value for n

```
#pragma pack(8)
```

Using **#pragma pack** with a value for 'n' will set the current alignment to 'n'. Valid alignments for ‘n’ are: 1,2,4,8, and 16.

#pragma pack using push

```
#pragma pack(push)
```

Using **#pragma pack** with push will push the current alignment on an internal stack of alignments.

#pragma pack using push, identifier

```
#pragma pack(push, ident)
```

Using **#pragma pack** with push and an identifier will associate the pushed alignment with 'identifier'.

#pragma pack using push and n

```
#pragma pack(push, 8)
#pragma pack(push, ident, 8)
```

Using **#pragma pack** with push with a value for 'n', will execute pragma pack push or pragma pack push identifier, and afterwards set the current alignment to 'n'.

#pragma pack using pop

```
#pragma pack(pop)
```

Using **#pragma pack** with pop will pop the alignment stack and set the alignment to the last alignment pushed. If the pop does not find a corresponding push, the entire stack of alignments is popped, and a warning is issued, and the alignment reverts to the starting -aX alignment..

#pragma pack using pop, identifier

```
#pragma pop(pop, ident)
```

Using **#pragma pack** with pop and an identifier will pop the stack until the identifier is found and set the alignment to the alignment pushed by the previous corresponding **#pragma pack(push, identifier)**. If the pop with identifier does not find the corresponding push with an identifier, the entire stack of alignments is popped, and a warning is issued to the user:

```
W8083: Pragma pack pop with no matching pack push
```

The alignment will then be reset to the starting -aX alignment.

#pragma pack using pop and n

```
#pragma pack(pop, 8)
#pragma pack(pop, ident, 8)
```

Using **#pragma pack** with pop and a value for 'n', will execute pragma pack pop or pragma pack pop identifier. Afterwards the current alignment is set to 'n', unless pop fails to find a corresponding push, in which case 'n' is ignored, a warning is issued, and the alignment reverts to the starting -aX alignment.

Error conditions

Specifying an 'identifier' without push or pop is an error.

Specifying an alignment different from 1,2,4,8,16 is an error.

Warning conditions

Using **#pragma pop** without a corresponding push issues a warning.

3.1.3.6.7.20 #pragma package

Syntax

```
#pragma package(smart_init)
#pragma package(smart_init, weak)
```

Description: smart_init argument

The **#pragma package(smart_init)** assures that packaged units are initialized in the order determined by their dependencies. (Included by default in package source file.) Typically, you would use the **#pragma package** for .cpp files that are built as packages.

This pragma affects the order of initialization of that compilation unit. For units, initialization occurs in the following order:

- 1. By their "uses" dependencies, that is, if unitA depends on unitB, unitB must be initialized before unitA.
- 2. The link order.
- 3. Priority order within the unit.

For regular object files (those not built as units), initialization happens first according to priority order and then link order. Changing the link order of the object files changes the order in which the global object constructors get called.

The following examples show how the initialization differs between units and regular object files.

Take as an example three unit files, A, B and C that are "smart initialized" with **#pragma package(smart_init)** and have priority values (defined by the priority parameter of the #pragma startup) set of 10, 20 and 30. The functions are named according to their priority value and the parent object file, so the names are a10, a20, a30, b10, and so on.

Since all three are units, and if A uses B and C and the link order is A, B then C, the order of initialization is:

B10 B20 B30 C10 C20 C30 A10 A20 A30

If the above were object files, not units, the order would be:

A10 B10 C10 A20 B20 C20 A30 B30 C30

The .cpp files that use **#pragma package(smart_init)** also require that any **#pragma link** references to other object files from a .cpp file that declares **#pragma package(smart_init)**, must be resolved by a unit. **#pragma link** references to non object files can still be resolved by libraries, etc.

Description: weak packages

The **#pragma package(smart_init, weak)** directive affects the way an object file is stored in a package's .bpi and .bpl files. If **#pragma package(smart_init, weak)** appears in a unit file, the compiler omits the unit from BPLs when possible, and creates

a non-packaged local copy of the unit when it is required by another application or package. A unit compiled with this directive is said to be "weakly packaged".

#pragma package(smart_init, weak) is used to eliminate conflicts among packages that may depend on the same external library.

Unit files containing the **#pragma package(smart_init, weak)** directive must not have global variables.

For more information about using weak packages, see Weak packaging.

See Also

Preprocessor Directives (see page 710)

3.1.3.6.7.21 #pragma region and #pragma end_region

Syntax

```
#pragma region <name> #pragma end_region
```

Description

These two pragmas allow the program to specify a region that can be collapsed and expanded, similar to the facility automatically provided for functions.

Use these pragmas by enclosing the code section as follows:

```
#pragma region name code to be collapsed/expanded ... #pragma
        end_region
```

The name is optional.

3.1.3.6.7.22 #pragma resource

Syntax

```
#pragma resource "*.xdfm"
```

Description

This pragma causes the file to be marked as a form unit and requires matching .dfm and header files. All such files are managed by the IDE.

If your form requires any variables, they must be declared immediately after the pragma resource is used. The declarations must be of the form

TFormName *Formname;

3.1.3.6.7.23 #pragma warn

Syntax

```
#pragma warn [+|-|.]xxx
```

Description

The **warn** pragma lets you override specific **-wxxx** command-line options or check Display Warnings. **xxx** is the three-letter or four-digit message identifier used by the command-line option.

+ turns on a warning while - disables the warning. The '.' restores a warning to the setting in Project Options.

3.1.3.6.8 Predefined Macros Overview

This section contains Predefined Macros Overview topics.

Topics

Name	Description
Predefined Macros (see page 708)	The compiler predefines certain global identifiers, known as manifest constants. Most global identifiers begin and end with two underscores (__). **Note:** For readability, underscores are often separated by a single blank space. In your source code, you should never insert whitespace between underscores.

3.1.3.6.8.1 Predefined Macros

The compiler predefines certain global identifiers, known as manifest constants. Most global identifiers begin and end with two underscores (__).

Note: For readability, underscores are often separated by a single blank space. In your source code, you should never insert whitespace between underscores.

Macro	Value	Description
__BCOPT__	1	Defined only in compilers that support optimization, therefore always defined.
__BCPLUSPLUS__	• 0x0570 for BDS 2006 • 0x0590 for C++Builder 2007 • 0x0591 for update 1 to C++Builder 2007 • 0x0592 for RAD Studio 2007 • 0x0593 for the December update to RAD Studio 2007 • 0x0610 for C++Builder 2009 and for C++Builder 2009 Update 1	Defined if you've selected C++ compilation; will increase in later releases.
__BOOL__	1	Indicates that the **bool** keyword is accepted.
__BORLANDC__	• 0x0570 for BDS 2006 • 0x0590 for C++Builder 2007 • 0x0591 for update 1 to C++Builder 2007 • 0x0592 for RAD Studio 2007 • 0x0593 for the December update to RAD Studio 2007 • 0x0610 for C++Builder 2009 and for C++Builder 2009 Update 1	Version number.
__CDECL__	1	Defined if Calling Convention is set to cdecl; otherwise undefined.

_CHAR_UNSIGNED	1	Undefined by default. Using the -K switch to make the default character unsigned causes this macro to be defined. Ultimately, the -K option controls how a **char** is extended when converted to an **int**. By default, the compiler sign-extends, but if you enable _CHAR_UNSIGNED_, then the compiler zero-extends characters when converting to **int**.
__CODEGEARC__	0x0610 for C++Builder 2009	Version number.
__CODEGUARD__		Defined whenever one of the CodeGuard compiler options is used; otherwise it is undefined.
__CONSOLE__	1	When defined, the macro indicates that the program is a console application.
_CPPUNWIND	1	Enable stack unwinding. This is true by default; use **-xd-**!ALink(OSCGExceptions1) to disable.
__cplusplus	1	Defined if in C++ mode; otherwise, undefined.
__DATE__	String literal	Date when processing began on the current file.
__DLL__	1	Defined whenever the -WD compiler option is used; otherwise it is undefined.
__FILE__	String literal	Name of the current file being processed.
__FLAT__	1	Defined when compiling in 32-bit flat memory model.
__FUNC__	String literal	Name of the current function being processed. More details.
__LINE__	Decimal constant	Number of the current source file line being processed.
_M_IX86	0x12c	Always defined. The default value is 300. You can change the value to 400 or 500 by using the /4 or /5 compiler options.
__MT__	1	Defined only if the -tWM option is used. It specifies that the multithread library is to be linked.
__PASCAL__	1	Defined if Calling Convention is set to Pascal; otherwise undefined.
_PUSHPOP_SUPPORTED	1	Always defined; allows Microsoft standard headers to use push and pop to verify whether a feature is supported.
_STDCALL_SUPPORTED	1	Always defined; defines the Microsoft stdcall calling convention.
__STDC__	1	Defined if you compile with the -A compiler option; otherwise, it is undefined.
__TCPLUSPLUS__	0x0570 0x0610 for C++Builder 2009	Version number.
__TEMPLATES__	1	Defined as 1 for C++ files (meaning that templates are supported); otherwise, it is undefined.
__TIME__	String literal	Time when processing began on the current file.
__TLS__	1	Thread Local Storage. Always true.

__TURBOC__	• 0x0570 for BDS 2006 • 0x0590 for C++Builder 2007 • 0x0591 for update 1 to C++Builder 2007 • 0x0592 for RAD Studio 2007 • 0x0593 for the December update to RAD Studio 2007 • 0x0610 for C++Builder 2009 and for C++Builder 2009 Update 1	Will increase in later releases.
_WCHAR_T		Defined only for C++ programs to indicate that **wchar_t** is an intrinsically defined data type.
_WCHAR_T_DEFINED		Defined only for C++ programs to indicate that **wchar_t** is an intrinsically defined data type.
_Windows	1	Defined when compiling on the Windows platform.
__WIN32__	1	Defined for console and GUI applications on the Windows platform.

Note: The predefined macros __DATE__

, **__FILE__** , **__FUNC__**, **__LINE__**, **__STDC__**, and **__TIME__** cannot be redefined or undefined.

3.1.3.6.9 Preprocessor Directives

This section contains C++ Preprocessor Directive topics.

Topics

Name	Description
Preprocessor Directives (see page 710)	Preprocessor directives are usually placed at the beginning of your source code, but they can legally appear at any point in a program. The preprocessor detects preprocessor directives (also known as control lines) and parses the tokens embedded in them. The preprocessor supports these directives:
# (null Directive) (see page 711)	**Syntax**

3.1.3.6.9.1 Preprocessor Directives

Preprocessor directives are usually placed at the beginning of your source code, but they can legally appear at any point in a program. The preprocessor detects preprocessor directives (also known as control lines) and parses the tokens embedded in them. The preprocessor supports these directives:

# (null directive)	#ifdef (see page 688)
#define (see page 690)	#ifndef (see page 688)
#elif (see page 688)	#undef (see page 691)
#else (see page 688)	#include (see page 692)
#endif (see page 688)	#line (see page 693)
#error (see page 692)	#pragma (see page 696)
#if (see page 688)	#import (see page 692)

Any line with a leading # is taken as a preprocessing directive, unless the # is within a string literal, in a character constant, or embedded in a comment. The initial # can be preceded or followed by whitespace (excluding new lines).

3.1.3.6.9.2 # (null Directive)

Syntax

#

Description

The null directive consists of a line containing the single character #. This line is always ignored.

3.1.4 C Runtime Library Reference

RAD Studio has several hundred functions, macros, and classes that you call from within your C and C++ programs to perform a wide variety of tasks, including low- and high-level I/O, string and file manipulation, memory allocation, process control, data conversion, mathematical calculations, and more.

Note: In the online help, each function, macro, and class in the C Runtime Library is listed only once . However, some functions, macros, and classes are defined in more than one header file.

For example, `_strerror` is defined in both string.h and stdio.h. For functions that are defined in several header files, the online help assigns the function to the first header file in alphabetic order. Thus, you will find `_strerror` listed in the help in stdio.h but not in string.h.

To find a function, macro, or class that is not listed in a header file in which you expect it, please use the help Index.

values.h (see page 1214)	The following functions, macros, and classes are provided in `values.h`:

3.1.4.1 alloc.h

The following functions, macros, and classes are provided in `alloc.h`:

Topics

Name	Description
_heapchk (see page 716)	**Header File** malloc.h **Category** Memory Routines **Syntax** `int _heapchk(void);` **Description** Checks and verifies the heap. _heapchk walks through the heap and examines each block, checking its pointers, size, and other critical attributes. **Return Value** One of the following values:

_heapmin (see page 717)	**Header File** malloc.h **Category** Memory Routines **Prototype** `int _heapmin(void);` **Description** Release unused heap areas. The _heapmin function returns unused areas of the heap to the operating system. This allows other processes to use blocks that have been allocated and then freed. Due to fragmentation of the heap, _heapmin might not always be able to return unused memory to the operating system; this is not an error. **Return Value** _heapmin returns 0 if it is successful, or -1 if an error occurs. **Portability**
_heapset (see page 717)	**Header File** malloc.h **Category** Memory Routines **Prototype** `int _heapset(unsigned int fillvalue);` **Description** Fills the free blocks on the heap with a constant value. _heapset checks the heap for consistency using the same methods as _heapchk. It then fills each free block in the heap with the value contained in the least significant byte of fillvalue. This function can be used to find heap-related problems. It does not guarantee that subsequently allocated blocks will be filled with the specified value. **Return Value** One of the following values:
_msize (see page 720)	**Header File** malloc.h **Category** Memory Routines **Prototype** `size_t _msize(void *block);` **Description** Returns the size of a heap block. _msize returns the size of the allocated heap block whose address is block. The block must have been allocated with malloc, calloc, or realloc. The returned size can be larger than the number of bytes originally requested when the block was allocated. **Return Value** _msize returns the size of the block in bytes. **Example**
_rtl_heapwalk (see page 720)	**Header File** malloc.h **Category** Memory Routines **Prototype** `int _rtl_heapwalk(_HEAPINFO *hi);` **Description** Inspects the heap node by node. **Note:** This function replaces _heapwalk which is obsolete. _rtl_heapwalk assumes the heap is correct. Use _heapchk to verify the heap before using _rtl_heapwalk. _HEAPOK is returned with the last block on the heap. _HEAPEND will be returned on the next call to _rtl_heapwalk. _rtl_heapwalk receives a pointer to a structure of type _HEAPINFO (declared in malloc.h). Note that the _HEAPINFO structure must be allocated on the heap (using malloc()). You can't pass the address of a variable declared on the stack. For the... more (see page 720)

calloc (see page 721)	**Header File** alloc.h, stdlib.h **Category** Memory Routines **Prototype** `void *calloc(size_t nitems, size_t size);` **Description** Allocates main memory. calloc provides access to the C memory heap. The heap is available for dynamic allocation of variable-sized blocks of memory. Many data structures, such as trees and lists, naturally employ heap memory allocation. calloc allocates a block of size nitems * size. The block is initialized to 0. **Return Value** calloc returns a pointer to the newly allocated block. If not enough space exists for the new block or if nitems or size is 0, calloc returns NULL. **Example**
free (see page 722)	**Header File** alloc.h, stdlib.h **Category** Memory Routines **Prototype** `void free(void *block);` **Description** Frees allocated block. free deallocates a memory block allocated by a previous call to calloc, malloc, or realloc. **Return Value** None. **Example**
heapcheck (see page 723)	**Header File** alloc.h **Category** Memory Routines **Prototype** `int heapcheck(void);` **Description** Checks and verifies the heap. heapcheck walks through the heap and examines each block, checking its pointers, size, and other critical attributes. **Return Value** The return value is less than 0 for an error and greater than 0 for success. The return values and their meaning are as follows:
heapcheckfree (see page 724)	**Header File** alloc.h **Category** Memory Routines **Prototype** `int heapcheckfree(unsigned int fillvalue);` **Description** Checks the free blocks on the heap for a constant value. **Return Value** The return value is less then 0 for an error and greater than 0 for success. The return values and their meaning are as follows:

heapchecknode (see page 725)	**Header File** alloc.h **Category** Memory Routines **Prototype** `int heapchecknode(void *node);` **Description** Checks and verifies a single node on the heap. If a node has been freed and heapchecknode is called with a pointer to the freed block, heapchecknode can return _BADNODE rather than the expected _FREEENTRY. This is because adjacent free blocks on the heap are merged, and the block in question no longer exists. **Return Value** One of the following values:
heapfillfree (see page 726)	**Header File** alloc.h **Category** Memory Routines **Prototype** `int heapfillfree(unsigned int fillvalue);` **Description** Fills the free blocks on the heap with a constant value. **Return Value** One of the following values:
heapwalk (see page 727)	**Header File** alloc.h **Category** Memory Routines **Prototype** `int heapwalk(struct heapinfo *hi);` **Description** heapwalk is used to “walk” through the heap, node by node. heapwalk assumes the heap is correct. Use heapcheck to verify the heap before using heapwalk. _HEAPOK is returned with the last block on the heap. _HEAPEND will be returned on the next call to heapwalk. heapwalk receives a pointer to a structure of type heapinfo (declared in alloc.h). For the first call to heapwalk, set the hi.ptr field to null. heapwalk returns with hi.ptr containing the address of the first block. hi.size holds the size of the... more (see page 727)
malloc (see page 728)	**Header File** alloc.h, stdlib.h **Category** Memory Routines **Prototype** `void *malloc(size_t size);` **Description** malloc allocates a block of size bytes from the memory heap. It allows a program to allocate memory explicitly as it’s needed, and in the exact amounts needed. Allocates main memory.The heap is used for dynamic allocation of variable-sized blocks of memory. Many data structures, for example, trees and lists, naturally employ heap memory allocation. In the large data models, all the space beyond the program stack to the end of available memory is available for the heap. **Return Value** On success, malloc returns a pointer to the... more (see page 728)

realloc (see page 729)	**Header File** alloc.h, stdlib.h **Category** Memory Routines **Prototype** `void *realloc(void *block, size_t size);` **Description** Reallocates main memory. realloc attempts to shrink or expand the previously allocated block to size bytes. If size is zero, the memory block is freed and NULL is returned. The block argument points to a memory block previously obtained by calling malloc, calloc, or realloc. If block is a NULL pointer, realloc works just like malloc. realloc adjusts the size of the allocated block to size, copying the contents to a new location if necessary. **Return Value** realloc returns the address of the reallocated block, which... more (see page 729)
stackavail (see page 729)	**Header File** malloc.h **Category** Memory Routines **Prototype** `size_t stackavail(void);` **Description** Gets the amount of available stack memory. stackavail returns the number of bytes available on the stack. This is the amount of dynamic memory that alloca can access. **Return Value** stackavail returns a size_t value indicating the number of bytes available. **Example**

3.1.4.1.1 _heapchk

Header File

malloc.h

Category

Memory Routines

Syntax

```
int _heapchk(void);
```

Description

Checks and verifies the heap.

_heapchk walks through the heap and examines each block, checking its pointers, size, and other critical attributes.

Return Value

One of the following values:

_HEAPBADNODE	A corrupted heap block has been found
_HEAPEMPTY	No heap exists
_HEAPOK	The heap appears to be uncorrupted

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.1.2 _heapmin

Header File

malloc.h

Category

Memory Routines

Prototype

```
int _heapmin(void);
```

Description

Release unused heap areas.

The _heapmin function returns unused areas of the heap to the operating system. This allows other processes to use blocks that have been allocated and then freed. Due to fragmentation of the heap, _heapmin might not always be able to return unused memory to the operating system; this is not an error.

Return Value

_heapmin returns 0 if it is successful, or -1 if an error occurs.

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.1.3 _heapset

Header File

malloc.h

Category

Memory Routines

Prototype

```
int _heapset(unsigned int fillvalue);
```

Description

Fills the free blocks on the heap with a constant value.

_heapset checks the heap for consistency using the same methods as _heapchk. It then fills each free block in the heap with the value contained in the least significant byte of fillvalue. This function can be used to find heap-related problems. It does not guarantee that subsequently allocated blocks will be filled with the specified value.

Return Value

One of the following values:

_HEAPOK	The heap appears to be uncorrupted
_HEAPEMPTY	No heap exists
_HEAPBADNODE	A corrupted heap block has been found

Example

```
#include <windowsx.h>
#include <malloc.h>
#include <stdio.h>
#include <stdlib.h>
BOOL InitApplication(HINSTANCE hInstance);
HWND InitInstance(HINSTANCE hInstance, int nCmdShow);
LRESULT FAR PASCAL _export MainWndProc(HWND hWnd, UINT message,
            WPARAM wParam, LPARAM lParam);
void ExampleHeapSet(HWND hWnd);
#pragma argsused
int PASCAL WinMain(HINSTANCE hInstance, HINSTANCE hPrevInstance,
        LPSTR lpCmdLine, int nCmdShow)
{

3.1.4.1.4 _msize

Header File

malloc.h

Category

Memory Routines

Prototype

```
size_t _msize(void *block);
```

Description

Returns the size of a heap block.

_msize returns the size of the allocated heap block whose address is block. The block must have been allocated with malloc, calloc, or realloc. The returned size can be larger than the number of bytes originally requested when the block was allocated.

Return Value

_msize returns the size of the block in bytes.

Example

```
#include <malloc.h>        /* malloc() _msize() */
#include <stdio.h>            /* printf() */
int main( )
{
  int size;
  int *buffer;
  buffer = malloc(100 * sizeof(int));
  size = _msize(buffer);
  printf("Allocated %d bytes for 100 integers\n", size);
  return(0);
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.1.5 _rtl_heapwalk

Header File

malloc.h

Category

Memory Routines

Prototype

```
int _rtl_heapwalk(_HEAPINFO *hi);
```

Description

Inspects the heap node by node.

Note: This function replaces _heapwalk which is obsolete.

_rtl_heapwalk assumes the heap is correct. Use _heapchk to verify the heap before using _rtl_heapwalk. _HEAPOK is returned with the last block on the heap. _HEAPEND will be returned on the next call to _rtl_heapwalk.

_rtl_heapwalk receives a pointer to a structure of type _HEAPINFO (declared in malloc.h). Note that the _HEAPINFO structure must be allocated on the heap (using malloc()). You can't pass the address of a variable declared on the stack.

For the first call to _rtl_heapwalk, set the hi._pentry field to NULL. _rtl_heapwalk returns with hi._pentry containing the address of the first block.

hi._size	holds the size of the block in bytes.
hi._useflag	is a flag that is set to _USEDENTRY if the block is currently in use. If the block is free, hi._useflag is set to _FREEENTRY.

Return Value

This function returns one of the following values:

_HEAPBADNODE	A corrupted heap block has been found
_HEAPBADPTR	The _pentry field does not point to a valid heap block
_HEAPEMPTY	No heap exists
_HEAPEND	The end of the heap has been reached
_HEAPOK	The _heapinfo block contains valid information about the next heap block

Example

```
#include <stdio.h>
#include <malloc.h>
#include <alloc.h>
#define NUM_PTRS  10
#define NUM_BYTES 16
int main( void )
{
   _HEAPINFO *hi;
   char *array[ NUM_PTRS ];
   int i;
   hi = (_HEAPINFO *) malloc( sizeof(_HEAPINFO) );
   for( i = 0; i < NUM_PTRS; i++ )
      array[ i ] = (char *) malloc( NUM_BYTES );
   for( i = 0; i < NUM_PTRS; i += 2 )
     free( array[ i ] );
   hi->_pentry = NULL;
   printf( "   Size   Status\n" );
   printf( "   ----   ------\n" );
   while( _rtl_heapwalk( hi ) == _HEAPOK )
     printf( "%7u    %s\n", hi->_size, hi->_useflag ? "used" : "free" );
   free( hi );
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.1.6 calloc

Header File

alloc.h, stdlib.h

Category

Memory Routines

Prototype

```
void *calloc(size_t nitems, size_t size);
```

Description

Allocates main memory.

calloc provides access to the C memory heap. The heap is available for dynamic allocation of variable-sized blocks of memory. Many data structures, such as trees and lists, naturally employ heap memory allocation.

calloc allocates a block of size nitems * size. The block is initialized to 0.

Return Value

calloc returns a pointer to the newly allocated block. If not enough space exists for the new block or if nitems or size is 0, calloc returns NULL.

Example

```
#include <stdio.h>
#include <alloc.h>
#include <string.h>
int main(void)
{
   char *str = NULL;
   /* allocate memory for string */
   str = (char *) calloc(10, sizeof(char));
   /* copy "Hello" into string */
   strcpy(str, "Hello");
   /* display string */
   printf("String is %s\n", str);
   /* free memory */
   free(str);
   return 0;
}
```

Portability

+	+	+	+

3.1.4.1.7 free

Header File

alloc.h, stdlib.h

Category

Memory Routines

Prototype

```
void free(void *block);
```

Description

Frees allocated block.

free deallocates a memory block allocated by a previous call to calloc, malloc, or realloc.

Return Value

None.

Example

```
#include <string.h>
#include <stdio.h>
#include <alloc.h>
int main(void)
{
   char *str;
   /* allocate memory for string */
   str = (char *) malloc(10);
   /* copy "Hello" to string */
   strcpy(str, "Hello");
   /* display string */
   printf("String is %s\n", str);
   /* free memory */
   free(str);
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
+	+	+	+

3.1.4.1.8 heapcheck

Header File

alloc.h

Category

Memory Routines

Prototype

```
int heapcheck(void);
```

Description

Checks and verifies the heap.

heapcheck walks through the heap and examines each block, checking its pointers, size, and other critical attributes.

Return Value

The return value is less than 0 for an error and greater than 0 for success. The return values and their meaning are as follows:

_HEAPCORRUPT	Heap has been corrupted
_HEAPEMPTY	No heap
_HEAPOK	Heap is verified

Example

```
#include <stdio.h>
#include <alloc.h>
#define NUM_PTRS  10
#define NUM_BYTES 16
int main(void)
{
   char *array[ NUM_PTRS ];
   int i;
   for( i = 0; i < NUM_PTRS; i++ )
      array[ i ] = (char *) malloc( NUM_BYTES );
   for( i = 0; i < NUM_PTRS; i += 2 )
      free( array[ i ] );
   if( heapcheck() == _HEAPCORRUPT )
      printf( "Heap is corrupted.\n" );
   else
      printf( "Heap is OK.\n" );
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.1.9 heapcheckfree

Header File

alloc.h

Category

Memory Routines

Prototype

```
int heapcheckfree(unsigned int fillvalue);
```

Description

Checks the free blocks on the heap for a constant value.

Return Value

The return value is less then 0 for an error and greater than 0 for success. The return values and their meaning are as follows:

_BADVALUE	A value other than the fill value was found
_HEAPCORRUPT	Heap has been corrupted
_HEAPEMPTY	No heap
_HEAPOK	Heap is accurate

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.1.10 heapchecknode

Header File

alloc.h

Category

Memory Routines

Prototype

```
int heapchecknode(void *node);
```

Description

Checks and verifies a single node on the heap.

If a node has been freed and heapchecknode is called with a pointer to the freed block, heapchecknode can return _BADNODE rather than the expected _FREEENTRY. This is because adjacent free blocks on the heap are merged, and the block in question no longer exists.

Return Value

One of the following values:

_BADNODE	Node could not be found
_FREEENTRY	Node is a free block
_HEAPCORRUPT	Heap has been corrupted
_HEAPEMPTY	No heap
_USEDENTRY	Node is a used block

Example

```
#include <stdio.h>
#include <alloc.h>
#define NUM_PTRS  10
#define NUM_BYTES 16
int main(void)
{
   char *array[ NUM_PTRS ];
   int i;
   for( i = 0; i < NUM_PTRS; i++ )
      array[ i ] = (char *) malloc( NUM_BYTES );
   for( i = 0; i < NUM_PTRS; i += 2 )
      free( array[ i ] );
   for( i = 0; i < NUM_PTRS; i++ )
   {
      printf( "Node %2d ", i );
      switch( heapchecknode( array[ i ] ) )
      {
         case _HEAPEMPTY:
              printf( "No heap.\n" );
              break;
         case _HEAPCORRUPT:
              printf( "Heap corrupt.\n" );
              break;
         case _BADNODE:
              printf( "Bad node.\n" );
              break;
         case _FREEENTRY:
```

```
                printf( "Free entry.\n" );
                break;
           case _USEDENTRY:
                printf( "Used entry.\n" );
                break;
           default:
                printf( "Unknown return code.\n" );
                 break;
        }
    }
    return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.1.11 heapfillfree

Header File

alloc.h

Category

Memory Routines

Prototype

```
int heapfillfree(unsigned int fillvalue);
```

Description

Fills the free blocks on the heap with a constant value.

Return Value

One of the following values:

_HEAPCORRUPT	Heap has been corrupted
_HEAPEMPTY	No heap
_HEAPOK	Heap is accurate

Example

```
#include <stdio.h>
#include <alloc.h>
#include <mem.h>
#define NUM_PTRS  10
#define NUM_BYTES 16
int main(void)
{
   char *array[ NUM_PTRS ];
   int i;
   int res;
   for( i = 0; i < NUM_PTRS; i++ )
      array[ i ] = (char *) malloc( NUM_BYTES );
   for( i = 0; i < NUM_PTRS; i += 2 )
      free( array[ i ] );
   if( heapfillfree( 1 ) < 0 )
   {
```

```
        printf( "Heap corrupted.\n" );
        return 1;
    }
    for( i = 1; i < NUM_PTRS; i += 2 )
        memset( array[ i ], 0, NUM_BYTES );
    res = heapcheckfree( 1 );
    if( res < 0 )
        switch( res )
        {
            case _HEAPCORRUPT:
                 printf( "Heap corrupted.\n" );
                 return 1;
            case _BADVALUE:
                 printf( "Bad value in free space.\n" );
                 return 1;
            default:
                 printf( "Unknown error.\n" );
                 return 1;
        }
    printf( "Test successful.\n" );
    return 0;
}
```

Portability

	+		

3.1.4.1.12 heapwalk

Header File

alloc.h

Category

Memory Routines

Prototype

```
int heapwalk(struct heapinfo *hi);
```

Description

heapwalk is used to “walk” through the heap, node by node.

heapwalk assumes the heap is correct. Use heapcheck to verify the heap before using heapwalk. _HEAPOK is returned with the last block on the heap. _HEAPEND will be returned on the next call to heapwalk.

heapwalk receives a pointer to a structure of type heapinfo (declared in alloc.h). For the first call to heapwalk, set the hi.ptr field to null. heapwalk returns with hi.ptr containing the address of the first block. hi.size holds the size of the block in bytes. hi.in_use is a flag that’s set if the block is currently in use.

Return Value

One of the following values:

_HEAPEMPTY	No heap exists
_HEAPEND	The end of the heap has been reached
_HEAPOK	The heapinfo block contains valid information about the next heap block

Example

```
Portability
<table htmltable<tr><th>POSIX</th><th>Win32</th><th>ANSI C</th><th>ANSI C++</th></tr><tr><td>
</td><td>+</td><td> </td><td> </td></tr></table
```

3.1.4.1.13 malloc

Header File

alloc.h, stdlib.h

Category

Memory Routines

Prototype

```
void *malloc(size_t size);
```

Description

malloc allocates a block of size bytes from the memory heap. It allows a program to allocate memory explicitly as it's needed, and in the exact amounts needed.

Allocates main memory.The heap is used for dynamic allocation of variable-sized blocks of memory. Many data structures, for example, trees and lists, naturally employ heap memory allocation.

In the large data models, all the space beyond the program stack to the end of available memory is available for the heap.

Return Value

On success, malloc returns a pointer to the newly allocated block of memory. If not enough space exists for the new block, it returns NULL. The contents of the block are left unchanged. If the argument size == 0, malloc returns NULL.

Example

```
#include <stdio.h>
#include <string.h>
#include <alloc.h>
#include <process.h>
int main(void)
{
    char *str;
    /* allocate memory for string */
    if ((str = (char *) malloc(10)) == NULL)
    {
       printf("Not enough memory to allocate buffer\n");
       exit(1);  /* terminate program if out of memory */
    }
    /* copy "Hello" into string */
    strcpy(str, "Hello");
    /* display string */
    printf("String is %s\n", str);
    /* free memory */
    free(str);
    return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
+	+	+	+

3.1.4.1.14 realloc

Header File

alloc.h, stdlib.h

Category

Memory Routines

Prototype

```
void *realloc(void *block, size_t size);
```

Description

Reallocates main memory.

realloc attempts to shrink or expand the previously allocated block to size bytes. If size is zero, the memory block is freed and NULL is returned. The block argument points to a memory block previously obtained by calling malloc, calloc, or realloc. If block is a NULL pointer, realloc works just like malloc.

realloc adjusts the size of the allocated block to size, copying the contents to a new location if necessary.

Return Value

realloc returns the address of the reallocated block, which can be different than the address of the original block.

If the block cannot be reallocated, realloc returns NULL.

If the value of size is 0, the memory block is freed and realloc returns NULL.

Example

```
#include <stdio.h>
#include <alloc.h>
#include <string.h>
int main(void)
{
   char *str;
   /* allocate memory for string */
   str = (char *) malloc(10);
   /* copy "Hello" into string */
   strcpy(str, "Hello");
   printf("String is %s\n  Address is %p\n", str, str);
   str = (char *) realloc(str, 20);
   printf("String is %s\n  New address is %p\n", str, str);
   /* free memory */
   free(str);
   return 0;
}
```

3.1.4.1.15 stackavail

Header File

malloc.h

Category

Memory Routines

Prototype

```
size_t stackavail(void);
```

Description

Gets the amount of available stack memory.

stackavail returns the number of bytes available on the stack. This is the amount of dynamic memory that alloca can access.

Return Value

stackavail returns a size_t value indicating the number of bytes available.

Example

```
#include <malloc.h>
#include <stdio.h>

int main(void)
{
  char *buf;

  printf("\nThe stack: %u\tstack pointer: %u", stackavail(), _SP);
  buf = (char *) alloca(100 * sizeof(char));
  printf("\nNow, the stack: %u\tstack pointer: %u", stackavail(), _SP);
  return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.2 assert.h

The following functions, macros, and classes are provided in `assert.h`:

Topics

Name	Description
NDEBUG #define (see page 731)	**Header File** assert.h **Description** NDEBUG means "Use #define to treat assert as a macro or a true function". Can be defined in a user program. If defined, assert is a true function; otherwise assert is a macro.

assert (see page 731)	**Header File**
	assert.h
	Category
	Diagnostic Routines
	Prototype
	`void assert(int test);`
	Description
	Tests a condition and possibly aborts.
	assert is a macro that expands to an **if** statement; if test evaluates to zero, the assert macro calls the _assert function
	`void _RTLENTRY _EXPFUNC _assert(char * __cond, char * __file, int __line);`
	and aborts the program. The _assert function calls abort and asserts the following a message on stderr:
	`Assertion failed: test, file filename, line linenum`
	The filename and linenum listed in the message are the source file name and line number where the assert macro appears.
	If you place the #define... more (see page 731)

3.1.4.2.1 NDEBUG #define

Header File

assert.h

Description

NDEBUG means "Use #define to treat assert as a macro or a true function".

Can be defined in a user program. If defined, assert is a true function; otherwise assert is a macro.

3.1.4.2.2 assert

Header File

assert.h

Category

Diagnostic Routines

Prototype

```
void assert(int test);
```

Description

Tests a condition and possibly aborts.

assert is a macro that expands to an **if** statement; if test evaluates to zero, the assert macro calls the _assert function

```
void _RTLENTRY _EXPFUNC _assert(char * __cond, char * __file, int __line);
```

and aborts the program. The _assert function calls abort and asserts the following a message on stderr:

```
Assertion failed: test, file filename, line linenum
```

The filename and linenum listed in the message are the source file name and line number where the assert macro appears.

If you place the #define NDEBUG directive ("no debugging") in the source code before the #include <assert.h> directive, the macro expands to a no-op, the effect is to comment out the assert statement.

Return Value

None.

Example

```
#include <assert.h>
#include <stdio.h>
#include <stdlib.h>
struct ITEM {
   int key;
   int value;
};
/* add item to list, make sure list is not  null */
void additem(struct ITEM *itemptr) {
   assert(itemptr != NULL);
   /* add item to list */
}
int main(void)
{
   additem(NULL);
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
+	+	+	+

3.1.4.3 conio.h

The following functions, macros, and classes are provided in `conio.h`:

Topics

Name	Description
_setcursortype (see page 740)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `void _setcursortype(int cur_t);` **Description** Selects cursor appearance. Sets the cursor type to
cgets (see page 741)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `char *cgets(char *str);` **Description** Reads a string from the console. cgets reads a string of characters from the console, storing the string (and the string length) in the location pointed to by str. cgets reads characters until it encounters a carriage-return/linefeed (CR/LF) combination, or until the maximum allowable number of characters have been read. If cgets reads a CR/LF combination, it replaces the combination with a \0 (null terminator) before storing the string. Before cgets is called, set str[0] to the maximum length of the string to be read. On return, str[1]... more (see page 741)

clreol (see page 742)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `void clreol(void);` **Description** Clears to end of line in text window. clreol clears all characters from the cursor position to the end of the line within the current text window, without moving the cursor. **Note:** This function should not be used in Win32 GUI applications. **Return Value** None. **Example**
clrscr (see page 743)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `void clrscr(void);` **Description** Clears the text-mode window. clrscr clears the current text window and places the cursor in the upper left corner (at position 1,1). **Note:** Do not use this function in Win32 GUI applications. **Return Value** None. **Example**
cprintf (see page 744)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `int cprintf(const char *format[, argument, ...]);` **Description** Writes formatted output to the screen. cprintf accepts a series of arguments, applies to each a format specifier contained in the format string pointed to by format, and outputs the formatted data directly to the current text window on the screen. There must be the same number of format specifiers as arguments. For details details on format specifiers, see printf Format Specifiers. The string is written either directly to screen memory or by way of a BIOS call, depending on the value of the global... more (see page 744)
cputs (see page 745)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `int cputs(const char *str);` **Description** Writes a string to the screen. cputs writes the null-terminated string str to the current text window. It does not append a newline character. The string is written either directly to screen memory or by way of a BIOS call, depending on the value of the global variable _directvideo. Unlike puts, cputs does not translate linefeed characters (\n) into carriage-return/linefeed character pairs (\r\n). **Note:** Do not use this function in Win32 GUI applications. **Return Value** cputs returns the last character printed. **Example**

cscanf (see page 746)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `int cscanf(char *format[, address, ...]);` **Description** Scans and formats input from the console. cscanf scans a series of input fields one character at a time, reading directly from the console. Then each field is formatted according to a format specifier passed to cscanf in the format string pointed to by format. Finally, cscanf stores the formatted input at an address passed to it as an argument following format, and echoes the input directly to the screen. There must be the same number of format specifiers and addresses as there are input fields.... more (see page 746)
delline (see page 747)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `void delline(void);` **Description** Deletes line in text window. delline deletes the line containing the cursor and moves all lines below it one line up. delline operates within the currently active text window. **Note:** Do not use this function in Win32 GUI applications. **Return Value** None. **Example**
getch (see page 747)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `int getch(void);` **Description** Gets character from keyboard, does not echo to screen. getch reads a single character directly from the keyboard, without echoing to the screen. **Note:** Do not use this function in Win32 GUI applications. **Return Value** getch returns the character read from the keyboard. **Example**
getche (see page 748)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `int getche(void);` **Description** Gets character from the keyboard, echoes to screen. getche reads a single character from the keyboard and echoes it to the current text window using direct video or BIOS. **Note:** Do not use this function in Win32 GUI applications. **Return Value** getche returns the character read from the keyboard. **Example**

getpass (see page 749)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `char *getpass(const char *prompt);` **Description** Reads a password. getpass reads a password from the system console after prompting with the null-terminated string prompt and disabling the echo. A pointer is returned to a null-terminated string of up to eight characters (not counting the null-terminator). **Note:** Do not use this function in Win32 GUI applications. **Return Value** The return value is a pointer to a static string that is overwritten with each call. **Example**
gettext (see page 750)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `int gettext(int left, int top, int right, int bottom, void *destin);` **Description** Copies text from text mode screen to memory. gettext stores the contents of an onscreen text rectangle defined by left, top, right, and bottom into the area of memory pointed to by destin. All coordinates are absolute screen coordinates not window-relative. The upper left corner is (1,1). gettext reads the contents of the rectangle into memory sequentially from left to right and top to bottom. Each position onscreen takes 2 bytes of memory: The first byte is the character in... more (see page 750)

gettextinfo (see page 751)	**Header File**
	conio.h
	Category
	Console I/O Routines
	Prototype
	`void gettextinfo(struct text_info *r);`
	Description
	Gets text mode video information.
	gettextinfo fills in the text_info structure pointed to by r with the current text video information.
	The text_info structure is defined in conio.h as follows:
	`struct text_info {`
	`unsigned char winleft; /* left window coordinate */`
	`unsigned char wintop; /* top window coordinate */`
	`unsigned char winright; /* right window coordinate */`
	`unsigned char winbottom; /* bottom window coordinate */`
	`unsigned char attribute; /* text attribute */`
	`unsigned char normattr; /* normal attribute */`
	`unsigned char currmode; /* BW40, BW80, C40, C80,...` more (see page 751)

gotoxy (see page 752)	**Header File** conio.h **Category** Console I/O Routines **Prototype** void gotoxy(int x, int y); **Description** Positions cursor in text window. gotoxy moves the cursor to the given position in the current text window. If the coordinates are in any way invalid the call to gotoxy is ignored. An example of this is a call to gotoxy(40,30) when (35,25) is the bottom right position in the window. Neither argument to gotoxy can be zero. **Note:**Do not use this function in Win32 GUI applications. **Return Value** None. **Example**
highvideo (see page 752)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `void highvideo(void);` **Description** Selects high-intensity characters. highvideo selects high-intensity characters by setting the high-intensity bit of the currently selected foreground color. This function does not affect any characters currently onscreen, but does affect those displayed by functions (such as cprintf) that perform direct video, text mode output after highvideo is called. **Note:** Do not use this function in Win32 GUI applications. **Return Value** None. **Example**
insline (see page 753)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `void insline(void);` **Description** Inserts a blank line in the text window. insline inserts an empty line in the text window at the cursor position using the current text background color. All lines below the empty one move down one line, and the bottom line scrolls off the bottom of the window. **Note:** Do not use this function in Win32 GUI applications. **Return Value** None. **Example**
kbhit (see page 754)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `int kbhit(void);` **Description** Checks for currently available keystrokes. kbhit checks to see if a keystroke is currently available. Any available keystrokes can be retrieved with getch or getche. **Note:** Do not use this function in Win32 GUI applications. **Return Value** If a keystroke is available, kbhit returns a nonzero value. Otherwise, it returns 0. **Example**

lowvideo (see page 755)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `void lowvideo(void);` **Description** Selects low-intensity characters. lowvideo selects low-intensity characters by clearing the high-intensity bit of the currently selected foreground color. This function does not affect any characters currently onscreen. It affects only those characters displayed by functions that perform text mode, direct console output after this function is called. **Note:** Do not use this function in Win32 GUI applications. **Return Value** None. **Example**
movetext (see page 755)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `int movetext(int left, int top, int right, int bottom, int destleft, int desttop);` **Description** Copies text onscreen from one rectangle to another. movetext copies the contents of the onscreen rectangle defined by left, top, right, and bottom to a new rectangle of the same dimensions. The new rectangle's upper left corner is position (destleft, desttop). All coordinates are absolute screen coordinates. Rectangles that overlap are moved correctly. movetext is a text mode function performing direct video output. **Note:**Do not use this function in Win32 GUI applications. **Return Value** On success, movetext... more (see page 755)
normvideo (see page 756)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `void normvideo(void);` **Description** Selects normal-intensity characters. normvideo selects normal characters by returning the text attribute (foreground and background) to the value it had when the program started. This function does not affect any characters currently on the screen, only those displayed by functions (such as cprintf) performing direct console output functions after normvideo is called. **Note:** Do not use this function in Win32 GUI applications. **Return Value** None. **Example**

putch (see page 757)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `int putch(int c);` **Description** Outputs character to screen. putch outputs the character c to the current text window. It is a text mode function performing direct video output to the console. putch does not translate linefeed characters (\n) into carriage-return/linefeed pairs. The string is written either directly to screen memory or by way of a BIOS call, depending on the value of the global variable _directvideo. **Note:** This function should not be used in Win32 GUI applications. **Return Value** On success, putch returns the character printed, c. On error, it returns EOF.... more (see page 757)
puttext (see page 758)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `int puttext(int left, int top, int right, int bottom, void *source);` **Description** Copies text from memory to the text mode screen. puttext writes the contents of the memory area pointed to by source out to the onscreen rectangle defined by left, top, right, and bottom. All coordinates are absolute screen coordinates, not window-relative. The upper left corner is (1,1). puttext places the contents of a memory area into the defined rectangle sequentially from left to right and top to bottom. Each position onscreen takes 2 bytes of memory: The first byte is... more (see page 758)
textattr (see page 759)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `void textattr(int newattr);` **Description** Sets text attributes. **Note:** Do not use this function in Win32 GUI applications. textattr lets you set both the foreground and background colors in a single call. (Normally, you set the attributes with textcolor and textbackground.) This function does not affect any characters currently onscreen; it affects only those characters displayed by functions (such as cprintf) performing text mode, direct video output after this function is called. The color information is encoded in the newattr parameter as follows: In this 8-bit newattr parameter: • bits 0-3 contain the 4-bit... more (see page 759)

textbackground (see page 760)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `void textbackground(int newcolor);` **Description** Selects new text background color. **Note:** Do not use this function in Win32 GUI applications. textbackground selects the background color. This function works for functions that produce output in text mode directly to the screen. newcolor selects the new background color. You can set newcolor to an integer from 0 to 7, or to one of the symbolic constants defined in conio.h. If you use symbolic constants, you must include conio.h. Once you have called textbackground, all subsequent functions using direct video output (such as cprintf) will use... more (see page 760)
textcolor (see page 761)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `void textcolor(int newcolor);` **Description** Selects new character color in text mode. **Note:** Do not use this function in Win32 GUI applications. textcolor selects the foreground character color. This function works for the console output functions. newcolor selects the new foreground color. You can set newcolor to an integer as given in the table below, or to one of the symbolic constants defined in conio.h. If you use symbolic constants, you must include conio.h. Once you have called textcolor, all subsequent functions using direct video output (such as cprintf) will use newcolor. textcolor... more (see page 761)
textmode (see page 762)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `void textmode(int newmode);` **Description** Puts screen in text mode. **Note:** Do not use this function in Win32 GUI applications. textmode selects a specific text mode. You can give the text mode (the argument newmode) by using a symbolic constant from the enumeration type text_modes (defined in conio.h). The most commonly used text_modes type constants and the modes they specify are given in the following table. Some additional values are defined in conio.h.
ungetch (see page 764)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `int ungetch(int ch);` **Description** Pushes a character back to the keyboard buffer. **Note:** Do not use this function in Win32 GUI applications. ungetch pushes the character ch back to the console, causing ch to be the next character read. The ungetch function fails if it is called more than once before the next read. **Return Value** On success, ungetch returns the character ch. On error, it returns EOF. **Example**

wherex (see page 764)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `int wherex(void);` **Description** Gives horizontal cursor position within window. **Note:** Do not use this function in Win32 GUI applications. wherex returns the x-coordinate of the current cursor position (within the current text window). **Return Value** wherex returns an integer in the range 1 to the number of columns in the current video mode. **Example**
wherey (see page 765)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `int wherey(void);` **Description** Gives vertical cursor position within window. **Note:** Do not use this function in Win32 GUI applications. wherey returns the y-coordinate of the current cursor position (within the current text window). **Return Value** wherey returns an integer in the range 1 to the number of rows in the current video mode. **Portability**
window (see page 766)	**Header File** conio.h **Category** Console I/O Routines **Prototype** `void window(int left, int top, int right, int bottom);` **Description** Defines active text mode window. **Note:** Do not use this function in Win32 GUI applications. window defines a text window onscreen. If the coordinates are in any way invalid, the call to window is ignored. left and top are the screen coordinates of the upper left corner of the window. right and bottom are the screen coordinates of the lower right corner. The minimum size of the text window is one column by one line. The default window is full screen, with... more (see page 766)

3.1.4.3.1 _setcursortype

Header File

conio.h

Category

Console I/O Routines

Prototype

```
void _setcursortype(int cur_t);
```

Description

Selects cursor appearance.

Sets the cursor type to

_NOCURSOR	Turns off the cursor
_NORMALCURSOR	Normal underscore cursor
_SOLIDCURSOR	Solid block cursor

Note: Do not use this function in Win32 GUI applications.

Return Value

None.

Example

```
#include <conio.h>
int main( )
{
  // tell the user what to do
  clrscr();
  cputs("Press any key three times.\n\r");
  cputs("Each time the cursor will change shape.\n\r");
  gotoxy(1,5);           // show a solid cursor
  cputs("Now the cursor is solid.\n\r");
  _setcursortype(_SOLIDCURSOR);
  while(!kbhit()) {};         // wait to proceed
  getch();
  gotoxy(1,5);           // remove the cursor
  cputs("Now the cursor is gone.");
  clreol();
  gotoxy(1,6);
  _setcursortype(_NOCURSOR);
  while(!kbhit()) {};         // wait to proceed
  getch();
  gotoxy(1,5);                 // show a normal cursor
  cputs("Now the cursor is normal.");
  clreol();
  gotoxy(1,6);
  _setcursortype(_NORMALCURSOR);
  while(!kbhit()) {};         // wait to proceed
  getch();
  clrscr();
  return(0);
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.2 cgets

Header File

conio.h

Category

Console I/O Routines

Prototype

```
char *cgets(char *str);
```

Description

Reads a string from the console.

cgets reads a string of characters from the console, storing the string (and the string length) in the location pointed to by str.

cgets reads characters until it encounters a carriage-return/linefeed (CR/LF) combination, or until the maximum allowable number of characters have been read. If cgets reads a CR/LF combination, it replaces the combination with a \0 (null terminator) before storing the string.

Before cgets is called, set str[0] to the maximum length of the string to be read. On return, str[1] is set to the number of characters actually read. The characters read start at str[2] and end with a null terminator. Thus, str must be at least str[0] plus 2 bytes long.

Note: Do not use this function for Win32 GUI applications.

Return Value

On success, cgets returns a pointer to str[2].

Example

```
#include <stdio.h>
#include <conio.h>
int main(void)
{
   char buffer[83];
   char *p;
   /* There is space for 80 characters plus the NULL terminator */
   buffer[0] = 81;
   printf("Input some chars:");
   p = cgets(buffer);
   printf("\ncgets read %d characters: \"%s\"\n", buffer[1], p);
   printf("The returned pointer is %p, buffer[0] is at %p\n", p, &buffer);
   /* Leave room for 5 characters plus the NULL terminator */
   buffer[0] = 6;
   printf("Input some chars:");
   p = cgets(buffer);
   printf("\ncgets read %d characters: \"%s\"\n", buffer[1], p);
   printf("The returned pointer is %p, buffer[0] is at %p\n", p, &buffer);
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.3 clreol

Header File

conio.h

Category

Console I/O Routines

Prototype

```
void clreol(void);
```

Description

Clears to end of line in text window.

clreol clears all characters from the cursor position to the end of the line within the current text window, without moving the cursor.

Note: This function should not be used in Win32 GUI applications.

Return Value

None.

Example

```
#include <conio.h>
int main(void)
{
   clrscr();
   cprintf("The function CLREOL clears all characters from the\r\n");
   cprintf("cursor position to the end of the line within the\r\n");
   cprintf("current text window, without moving the cursor.\r\n");
   cprintf("Press any key to continue . . .");
   gotoxy(14, 4);
   getch();
   clreol();
   getch();
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.4 clrscr

Header File

conio.h

Category

Console I/O Routines

Prototype

```
void clrscr(void);
```

Description

Clears the text-mode window.

clrscr clears the current text window and places the cursor in the upper left corner (at position 1,1).

Note: Do not use this function in Win32 GUI applications.

Return Value

None.

Example

```
#include <conio.h>
int main(void)
{
   int i;
   clrscr();
```

```
    for (i = 0; i < 20; i++)
       cprintf("%d\r\n", i);
    cprintf("\r\nPress any key to clear screen");
    getch();
    clrscr();
    cprintf("The screen has been cleared!");
    getch();
    return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.5 cprintf

Header File

conio.h

Category

Console I/O Routines

Prototype

```
int cprintf(const char *format[, argument, ...]);
```

Description

Writes formatted output to the screen.

cprintf accepts a series of arguments, applies to each a format specifier contained in the format string pointed to by format, and outputs the formatted data directly to the current text window on the screen. There must be the same number of format specifiers as arguments.

For details details on format specifiers, see printf Format Specifiers.

The string is written either directly to screen memory or by way of a BIOS call, depending on the value of the global variable _directvideo.

Unlike fprintf and printf, cprintf does not translate linefeed characters (\n) into carriage-return/linefeed character pairs (\r\n). Tab characters (specified by \t) are not expanded into spaces.

Note: Do not use this function in Win32 GUI applications.

Return Value

cprintf returns the number of characters output.

Example

```
#include <conio.h>
int main(void)
{
   /* clear the screen */
   clrscr();
   /* create a text window */
   window(10, 10, 80, 25);
   /* output some text in the window */
   cprintf("Hello world\r\n");
   /* wait for a key */
```

```
   getch();
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.6 cputs

Header File

conio.h

Category

Console I/O Routines

Prototype

```
int cputs(const char *str);
```

Description

Writes a string to the screen.

cputs writes the null-terminated string str to the current text window. It does not append a newline character.

The string is written either directly to screen memory or by way of a BIOS call, depending on the value of the global variable _directvideo. Unlike puts, cputs does not translate linefeed characters (\n) into carriage-return/linefeed character pairs (\r\n).

Note: Do not use this function in Win32 GUI applications.

Return Value

cputs returns the last character printed.

Example

```
#include <conio.h>
int main(void)
{
   /* clear the screen */
   clrscr();
   /* create a text window */
   window(10, 10, 80, 25);
   /* output some text in the window */
   cputs("This is within the window\r\n");
   /* wait for a key */
   getch();
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.7 cscanf

Header File

conio.h

Category

Console I/O Routines

Prototype

```
int cscanf(char *format[, address, ...]);
```

Description

Scans and formats input from the console.

cscanf scans a series of input fields one character at a time, reading directly from the console. Then each field is formatted according to a format specifier passed to cscanf in the format string pointed to by format. Finally, cscanf stores the formatted input at an address passed to it as an argument following format, and echoes the input directly to the screen. There must be the same number of format specifiers and addresses as there are input fields.

Note: For details on format specifiers, see scanf Format Specifiers.

cscanf might stop scanning a particular field before it reaches the normal end-of-field (whitespace) character, or it might terminate entirely for a number of reasons. See scanf for a discussion of possible causes.

Note: Do not use this function in Win32 GUI applications.

Return Value

cscanf returns the number of input fields successfully scanned, converted, and stored; the return value does not include scanned fields that were not stored. If no fields were stored, the return value is 0.

If cscanf attempts to read at end-of-file , the return value is EOF.

Example

```
#include <conio.h>
int main(void)
{
   char string[80];
   /* clear the screen */
   clrscr();
   /* Prompt the user for input */
   cprintf("Enter a string with no spaces:");
   /* read the input */
   cscanf("%s", string);
   /* display what was read */
   cprintf("\r\nThe string entered is: %s", string);
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.8 delline

Header File

conio.h

Category

Console I/O Routines

Prototype

```
void delline(void);
```

Description

Deletes line in text window.

delline deletes the line containing the cursor and moves all lines below it one line up. delline operates within the currently active text window.

Note: Do not use this function in Win32 GUI applications.

Return Value

None.

Example

```
#include <conio.h>
int main(void)
{
   clrscr();
   cprintf("The function DELLINE deletes the line containing the\r\n");
   cprintf("cursor and moves all lines below it one line up.\r\n");
   cprintf("DELLINE operates within the currently active text\r\n");
   cprintf("window.  Press any key to continue . . .");
   gotoxy(1,2);  /* Move the cursor to the second line and first column */
   getch();
   delline();
   getch();
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.9 getch

Header File

conio.h

Category

Console I/O Routines

Prototype

```
int getch(void);
```

Description

Gets character from keyboard, does not echo to screen.

getch reads a single character directly from the keyboard, without echoing to the screen.

Note: Do not use this function in Win32 GUI applications.

Return Value

getch returns the character read from the keyboard.

Example

```
#include <conio.h>
#include <stdio.h>
int main(void)
{
  int c;
  int extended = 0;
  c = getch();
  if (!c)
    extended = getch();
  if (extended)
    printf("The character is extended\n");
  else
    printf("The character isn't extended\n");
  return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.10 getche

Header File

conio.h

Category

Console I/O Routines

Prototype

```
int getche(void);
```

Description

Gets character from the keyboard, echoes to screen.

getche reads a single character from the keyboard and echoes it to the current text window using direct video or BIOS.

Note: Do not use this function in Win32 GUI applications.

Return Value

getche returns the character read from the keyboard.

Example

```
#include <stdio.h>
#include <conio.h>
```

```
int main(void)
{
   char ch;
   printf("Input a character:");
   ch = getche();
   printf("\nYou input a '%c'\n", ch);
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.11 getpass

Header File

conio.h

Category

Console I/O Routines

Prototype

```
char *getpass(const char *prompt);
```

Description

Reads a password.

getpass reads a password from the system console after prompting with the null-terminated string prompt and disabling the echo. A pointer is returned to a null-terminated string of up to eight characters (not counting the null-terminator).

Note: Do not use this function in Win32 GUI applications.

Return Value

The return value is a pointer to a static string that is overwritten with each call.

Example

```
#include <conio.h>

int main(void)
{
   char *password;

   password = getpass("Input a password:");
   cprintf("The password is: %s\r\n", password);
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.12 gettext

Header File

conio.h

Category

Console I/O Routines

Prototype

```
int gettext(int left, int top, int right, int bottom, void *destin);
```

Description

Copies text from text mode screen to memory.

gettext stores the contents of an onscreen text rectangle defined by left, top, right, and bottom into the area of memory pointed to by destin.

All coordinates are absolute screen coordinates not window-relative. The upper left corner is (1,1). gettext reads the contents of the rectangle into memory sequentially from left to right and top to bottom.

Each position onscreen takes 2 bytes of memory: The first byte is the character in the cell and the second is the cell's video attribute. The space required for a rectangle w columns wide by h rows high is defined as

bytes = (h rows) x (w columns) x 2

Note: Do not use this function in Win32 GUI applications.

Return Value

gettext returns 1 if the operation succeeds.

On error, it returns 0 (for example, if it fails because you gave coordinates outside the range of the current screen mode).

Example

```
#include <conio.h>

char buffer[4096];
int main(void)
{
   int i;
   clrscr();
   for (i = 0; i <= 20; i++)
      cprintf("Line #%d\r\n", i);
   gettext(1, 1, 80, 25, buffer);
   gotoxy(1, 25);
   cprintf("Press any key to clear screen...");
   getch();
   clrscr();
   gotoxy(1, 25);
   cprintf("Press any key to restore screen...");
   getch();
   puttext(1, 1, 80, 25, buffer);
   gotoxy(1, 25);
   cprintf("Press any key to quit...");
   getch();
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.13 gettextinfo

Header File

conio.h

Category

Console I/O Routines

Prototype

```
void gettextinfo(struct text_info *r);
```

Description

Gets text mode video information.

gettextinfo fills in the text_info structure pointed to by r with the current text video information.

The text_info structure is defined in conio.h as follows:

```
struct text_info {
unsigned char winleft; /* left window coordinate */
unsigned char wintop; /* top window coordinate */
unsigned char winright; /* right window coordinate */
unsigned char winbottom; /* bottom window coordinate */
unsigned char attribute; /* text attribute */
unsigned char normattr; /* normal attribute */
unsigned char currmode; /* BW40, BW80, C40, C80, or C4350 */
unsigned char screenheight; /* text screen's height */
unsigned char screenwidth; /* text screen's width */
unsigned char curx; /* x-coordinate in current window */
unsigned char cury; /* y-coordinate in current window */
};
```

Note: Do not use this function in Win32 GUI applications.

Return Value

None. Results are returned in the structure pointed to by r.

Example

```
#include <conio.h>
int main(void)
 {
   struct text_info ti;
   gettextinfo(&ti);
   cprintf("window left      %2d\r\n",ti.winleft);
   cprintf("window top       %2d\r\n",ti.wintop);
```

```
    cprintf("window right     %2d\r\n",ti.winright);
    cprintf("window bottom    %2d\r\n",ti.winbottom);
    cprintf("attribute        %2d\r\n",ti.attribute);
    cprintf("normal attribute %2d\r\n",ti.normattr);
    cprintf("current mode     %2d\r\n",ti.currmode);
    cprintf("screen height    %2d\r\n",ti.screenheight);
    cprintf("screen width     %2d\r\n",ti.screenwidth);
    cprintf("current x        %2d\r\n",ti.curx);
    cprintf("current y        %2d\r\n",ti.cury);
    return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.14 gotoxy

Header File

conio.h

Category

Console I/O Routines

Prototype

```
void gotoxy(int x, int y);
```

Description

Positions cursor in text window.

gotoxy moves the cursor to the given position in the current text window. If the coordinates are in any way invalid the call to gotoxy is ignored. An example of this is a call to gotoxy(40,30) when (35,25) is the bottom right position in the window. Neither argument to gotoxy can be zero.

Note: Do not use this function in Win32 GUI applications.

Return Value

None.

Example

```
#include <conio.h>
int main(void)
{
    clrscr();
    gotoxy(35, 12);
    cprintf("Hello world");
    getch();
    return 0;
}
```

3.1.4.3.15 highvideo

Header File

conio.h

Category

Console I/O Routines

Prototype

```
void highvideo(void);
```

Description

Selects high-intensity characters.

highvideo selects high-intensity characters by setting the high-intensity bit of the currently selected foreground color.

This function does not affect any characters currently onscreen, but does affect those displayed by functions (such as cprintf) that perform direct video, text mode output after highvideo is called.

Note: Do not use this function in Win32 GUI applications.

Return Value

None.

Example

```
#include <conio.h>
int main(void)
{
clrscr();
lowvideo();
cprintf("Low Intensity text\r\n");
highvideo();
gotoxy(1,2);
cprintf("High Intensity Text\r\n");
return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.16 insline

Header File

conio.h

Category

Console I/O Routines

Prototype

```
void insline(void);
```

Description

Inserts a blank line in the text window.

insline inserts an empty line in the text window at the cursor position using the current text background color. All lines below the empty one move down one line, and the bottom line scrolls off the bottom of the window.

Note: Do not use this function in Win32 GUI applications.

Return Value

None.

Example

```
#include <conio.h>
int main(void)
{
    clrscr();
    cprintf("INSLINE inserts an empty line in the text window\r\n");
 cprintf("at the cursor position using the current text\r\n");
    cprintf("background color.  All lines below the empty one\r\n");
    cprintf("move down one line and the bottom line scrolls\r\n");
 cprintf("off the bottom of the window.\r\n");
    cprintf("\r\nPress any key to continue:");
 gotoxy(1, 3);
 getch();
    insline();
    getch();
 return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.17 kbhit

Header File

conio.h

Category

Console I/O Routines

Prototype

```
int kbhit(void);
```

Description

Checks for currently available keystrokes.

kbhit checks to see if a keystroke is currently available. Any available keystrokes can be retrieved with getch or getche.

Note: Do not use this function in Win32 GUI applications.

Return Value

If a keystroke is available, kbhit returns a nonzero value. Otherwise, it returns 0.

Example

```
#include <conio.h>
int main(void)
{
 cprintf("Press any key to continue:");
    while (!kbhit()) /* do nothing */ ;
    cprintf("\r\nA key was pressed...\r\n");
    return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.18 lowvideo

Header File

conio.h

Category

Console I/O Routines

Prototype

```
void lowvideo(void);
```

Description

Selects low-intensity characters.

lowvideo selects low-intensity characters by clearing the high-intensity bit of the currently selected foreground color.

This function does not affect any characters currently onscreen. It affects only those characters displayed by functions that perform text mode, direct console output after this function is called.

Note: Do not use this function in Win32 GUI applications.

Return Value

None.

Example

```
#include <conio.h>
int main(void)
{
clrscr();
highvideo();
   cprintf("High Intensity Text\r\n");
   lowvideo();
gotoxy(1,2);
   cprintf("Low Intensity Text\r\n");
return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.19 movetext

Header File

conio.h

Category

Console I/O Routines

Prototype

```
int movetext(int left, int top, int right, int bottom, int destleft, int desttop);
```

Description

Copies text onscreen from one rectangle to another.

movetext copies the contents of the onscreen rectangle defined by left, top, right, and bottom to a new rectangle of the same dimensions. The new rectangle's upper left corner is position (destleft, desttop).

All coordinates are absolute screen coordinates. Rectangles that overlap are moved correctly.

movetext is a text mode function performing direct video output.

Note: Do not use this function in Win32 GUI applications.

Return Value

On success, movetext returns nonzero.

On error (for example, if it failed because you gave coordinates outside the range of the current screen mode), movetext returns 0.

Example

```
#include <conio.h>
#include <string.h>
int main(void)
{
    char *str = "This is a test string";
    clrscr();
    cputs(str);
    getch();
    movetext(1, 1, strlen(str), 2, 10, 10);
    getch();
    return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.20 normvideo

Header File

conio.h

Category

Console I/O Routines

Prototype

```
void normvideo(void);
```

Description

Selects normal-intensity characters.

normvideo selects normal characters by returning the text attribute (foreground and background) to the value it had when the program started.

This function does not affect any characters currently on the screen, only those displayed by functions (such as cprintf) performing direct console output functions after normvideo is called.

Note: Do not use this function in Win32 GUI applications.

Return Value

None.

Example

```
#include <conio.h>
int main(void)
{
    normvideo();
    cprintf("NORMAL Intensity Text\r\n");
 return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.21 putch

Header File

conio.h

Category

Console I/O Routines

Prototype

```
int putch(int c);
```

Description

Outputs character to screen.

putch outputs the character c to the current text window. It is a text mode function performing direct video output to the console. putch does not translate linefeed characters (\n) into carriage-return/linefeed pairs.

The string is written either directly to screen memory or by way of a BIOS call, depending on the value of the global variable _directvideo.

Note: This function should not be used in Win32 GUI applications.

Return Value

On success, putch returns the character printed, c. On error, it returns EOF.

Example

```
#include <stdio.h>
#include <conio.h>
int main(void)
{
```

```
  char ch = 0;
  printf("Input a string:");
  while ((ch != '\r'))
  {
    ch = getch();
    putch(ch);
  }
  return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.22 puttext

Header File

conio.h

Category

Console I/O Routines

Prototype

```
int puttext(int left, int top, int right, int bottom, void *source);
```

Description

Copies text from memory to the text mode screen.

puttext writes the contents of the memory area pointed to by source out to the onscreen rectangle defined by left, top, right, and bottom.

All coordinates are absolute screen coordinates, not window-relative. The upper left corner is (1,1).

puttext places the contents of a memory area into the defined rectangle sequentially from left to right and top to bottom.

Each position onscreen takes 2 bytes of memory: The first byte is the character in the cell, and the second is the cell's video attribute. The space required for a rectangle w columns wide by h rows high is defined as

bytes = (h rows) x (w columns) x 2

puttext is a text mode function performing direct video output.

Note: This function should not be used in Win32 GUI applications.

Return Value

puttext returns a nonzero value if the operation succeeds; it returns 0 if it fails (for example, if you gave coordinates outside the range of the current screen mode).

Example

```
#include <conio.h>
int main(void)
{
   char buffer[512];
   /* put some text to the console */
   clrscr();
   gotoxy(20, 12);
   cprintf("This is a test.  Press any key to continue ...");
```

```
    getch();
    /* grab screen contents */
    gettext(20, 12, 36, 21,buffer);
    clrscr();
    /* put selected characters back to the screen */
    gotoxy(20, 12);
    puttext(20, 12, 36, 21, buffer);
    getch();
    return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.23 textattr

Header File

conio.h

Category

Console I/O Routines

Prototype

```
void textattr(int newattr);
```

Description

Sets text attributes.

Note: Do not use this function in Win32 GUI applications.

textattr lets you set both the foreground and background colors in a single call. (Normally, you set the attributes with textcolor and textbackground.)

This function does not affect any characters currently onscreen; it affects only those characters displayed by functions (such as cprintf) performing text mode, direct video output after this function is called.

The color information is encoded in the newattr parameter as follows:

In this 8-bit newattr parameter:

- bits 0-3 contain the 4-bit foreground color (0 to 15).
- bits 4-6 contain the 3-bit background color (0 to 7).
- bit 8 is the blink-enable bit.

If the blink-enable bit is on, the character blinks. This can be accomplished by adding the constant BLINK to the attribute.

- If you use the symbolic color constants defined in conio.h for creating text attributes with textattr, note the following limitations on the color you select for the background:
- You can select only one of the first eight colors for the background.
- You must shift the selected background color left by 4 bits to move it into the correct bit positions.

These symbolic constants are listed in the following table:

Return Value

None.

Example

```
#include <conio.h>
int main(void)
{
   int i;
   clrscr();
   for (i=0; i<9; i++)
   {
       textattr(i + ((i+1) << 4));
       cprintf("This is a test\r\n");
   }
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.24 textbackground

Header File

conio.h

Category

Console I/O Routines

Prototype

```
void textbackground(int newcolor);
```

Description

Selects new text background color.

Note: Do not use this function in Win32 GUI applications.

textbackground selects the background color. This function works for functions that produce output in text mode directly to the screen. newcolor selects the new background color. You can set newcolor to an integer from 0 to 7, or to one of the symbolic constants defined in conio.h. If you use symbolic constants, you must include conio.h.

Once you have called textbackground, all subsequent functions using direct video output (such as cprintf) will use newcolor. textbackground does not affect any characters currently onscreen.

The following table lists the symbolic constants and the numeric values of the allowable colors:

BLACK	0
BLUE	1
GREEN	2
CYAN	3
RED	4
MAGENTA	5
BROWN	6
LIGHTGRAY	7

Return Value

None.

Example

```
#include <conio.h>
int main(void)
{
   int i, j;
   clrscr();
   for (i=0; i<9; i++)
   {
       for (j=0; j<80; j++)
          cprintf("C");
       cprintf("\r\n");
       textcolor(i+1);
       textbackground(i);
   }
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.25 textcolor

Header File

conio.h

Category

Console I/O Routines

Prototype

```
void textcolor(int newcolor);
```

Description

Selects new character color in text mode.

Note: Do not use this function in Win32 GUI applications.

textcolor selects the foreground character color. This function works for the console output functions. newcolor selects the new foreground color. You can set newcolor to an integer as given in the table below, or to one of the symbolic constants defined in conio.h. If you use symbolic constants, you must include conio.h.

Once you have called textcolor, all subsequent functions using direct video output (such as cprintf) will use newcolor. textcolor does not affect any characters currently onscreen.

The following table lists the allowable colors (as symbolic constants) and their numeric values:

BLACK	0
BLUE	1
GREEN	2
CYAN	3

RED	4
MAGENTA	5
BROWN	6
LIGHTGRAY	7
DARKGRAY	8
LIGHTBLUE	9
LIGHTGREEN	10
LIGHTCYAN	11
LIGHTRED	12
LIGHTMAGENTA	13
YELLOW	14
WHITE	15
BLINK	128

You can make the characters blink by adding 128 to the foreground color. The predefined constant BLINK exists for this purpose.

For example:

```
textcolor(CYAN + BLINK);
```

Note: Some monitors do not recognize the intensity signal used to create the eight “light” colors (8-15). On such monitors, the light colors are displayed as their “dark” equivalents (0-7). Also, systems that do not display in color can treat these numbers as shades of one color, special patterns, or special attributes (such as underlined, bold, italics, and so on). Exactly what you’ll see on such systems depends on your hardware.

Return Value

None.

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.26 textmode

Header File

conio.h

Category

Console I/O Routines

Prototype

```
void textmode(int newmode);
```

Description

Puts screen in text mode.

Note: Do not use this function in Win32 GUI applications.

textmode selects a specific text mode.

You can give the text mode (the argument newmode) by using a symbolic constant from the enumeration type text_modes (defined in conio.h).

The most commonly used text_modes type constants and the modes they specify are given in the following table. Some additional values are defined in conio.h.

LASTMODE	Previous text mode
BW40	Black and white, 40 columns
C40	Color, 40 columns
BW80	Black and white, 80 columns
C80	Color, 80 columns
MONO	Monochrome, 80 columns
C4350	EGA 43-line and VGA 50-line modes

When textmode is called, the current window is reset to the entire screen, and the current text attributes are reset to normal, corresponding to a call to normvideo.

Specifying LASTMODE to textmode causes the most recently selected text mode to be reselected.

textmode should be used only when the screen or window is in text mode (presumably to change to a different text mode). This is the only context in which textmode should be used. When the screen is in graphics mode, use restorecrtmode instead to escape temporarily to text mode.

Return Value

None.

Example

```
#include <conio.h>
int main(void)
{
   textmode(BW40);
   cprintf("ABC");
   getch();
   textmode(C40);
   cprintf("ABC");
   getch();
   textmode(BW80);
   cprintf("ABC");
   getch();
   textmode(C80);
   cprintf("ABC");
   getch();
   textmode(MONO);
   cprintf("ABC");
   getch();
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.27 ungetch

Header File

conio.h

Category

Console I/O Routines

Prototype

```
int ungetch(int ch);
```

Description

Pushes a character back to the keyboard buffer.

Note: Do not use this function in Win32 GUI applications.

ungetch pushes the character ch back to the console, causing ch to be the next character read. The ungetch function fails if it is called more than once before the next read.

Return Value

On success, ungetch returns the character ch.

On error, it returns EOF.

Example

```
#include <stdio.h>
#include <ctype.h>
#include <conio.h>
int main( void )
{
   int i=0;
   char ch;
   puts("Input an integer followed by a char:");
   /* read chars until non digit or EOF */
   while((ch = getche()) != EOF && isdigit(ch))
      i = 10 * i + ch - 48; /* convert ASCII into int value */
   /* if non digit char was read, push it back into input buffer */
   if (ch != EOF)
      ungetch(ch);
   printf("\n\ni = %d, next char in buffer = %c\n", i, getch());
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.28 wherex

Header File

conio.h

Category

Console I/O Routines

Prototype

```
int wherex(void);
```

Description

Gives horizontal cursor position within window.

Note: Do not use this function in Win32 GUI applications.

wherex returns the x-coordinate of the current cursor position (within the current text window).

Return Value

wherex returns an integer in the range 1 to the number of columns in the current video mode.

Example

```
#include <conio.h>
int main(void)
{
   clrscr();
   gotoxy(10,10);
   cprintf("Current location is X: %d  Y: %d\r\n", wherex(), wherey());
   getch();
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.29 wherey

Header File

conio.h

Category

Console I/O Routines

Prototype

```
int wherey(void);
```

Description

Gives vertical cursor position within window.

Note: Do not use this function in Win32 GUI applications.

wherey returns the y-coordinate of the current cursor position (within the current text window).

Return Value

wherey returns an integer in the range 1 to the number of rows in the current video mode.

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.3.30 window

Header File

conio.h

Category

Console I/O Routines

Prototype

```
void window(int left, int top, int right, int bottom);
```

Description

Defines active text mode window.

Note: Do not use this function in Win32 GUI applications.

window defines a text window onscreen. If the coordinates are in any way invalid, the call to window is ignored.

left and top are the screen coordinates of the upper left corner of the window.

right and bottom are the screen coordinates of the lower right corner.

The minimum size of the text window is one column by one line. The default window is full screen, with the coordinates:

1,1,C,R

where C is the number of columns in the current video mode, and R is the number of rows.

Return Value

None.

Example

```
#include <conio.h>
int main(void)
{
   window(10,10,40,11);
   textcolor(BLACK);
   textbackground(WHITE);
   cprintf("This is a test\r\n");
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.4 ctype.h

The following functions, macros, and classes are provided in `ctype.h`:

Topics

Name	Description
_ctype (see page 772)	**Header File** ctype.h **Syntax** `extern char _ctype[];` **Description** _ctype is an array of character attribute information indexed by ASCII value + 1. Each entry is a set of bits describing the character. This array is used by isdigit, isprint, and so on.
_IS_xxx #defines (see page 772)	**Header File** ctype.h **Description** Bit settings in the _ctype[] used by the is... character macros.
_tolower (see page 772)	**Header File** ctype.h **Category** Conversion Routines **Prototype** `int _tolower(int ch);` **Description** _tolower is a macro that does the same conversion as tolower, except that it should be used only when ch is known to be uppercase (AZ). To use _tolower, you must include ctype.h. **Return Value** _tolower returns the converted value of ch if it is uppercase; otherwise, the result is undefined. **Example**
_toupper (see page 773)	**Header File** ctype.h **Category** Conversion Routines **Prototype** `int _toupper(int ch);` **Description** Translates characters to uppercase. _toupper is a macro that does the same conversion as toupper, except that it should be used only when ch is known to be lowercase (a to z). To use _toupper, you must include ctype.h. **Return Value** _toupper returns the converted value of ch if it is lowercase; otherwise, the result is undefined. **Example**

isalnum, __iscsym, iswalnum, _ismbcalnum (see page 774)	**Header File**
	ctype.h, mbstring.h
	Category
	Classification Routines
	Prototype
	`int isalnum(int c);`
	`int __iscsym(int c);`
	`int iswalnum(wint_t c);`
	`int _ismbcalnum(unsigned int c);`
	Description
	Tests for an alphanumeric character.
	isalnum is a macro that classifies ASCII-coded integer values by table lookup. The macro is affected by the current locale's LC_CTYPE category. For the default C locale, c is a letter (A to Z or a to z) or a digit (0 to 9).
	You can make this macro available as a function by undefining (**#undef**) it.
	Return Value
	It is a predicate returning nonzero for true and 0 for false.... more (see page 774)

isalpha, __iscsymf, iswalpha, _ismbcalpha (see page 775)	**Header File**
	ctype.h, mbstring.h
	Category
	Classification Routines
	Prototype
	`int isalpha(int c);`
	`int __iscsymf(int c);`
	`int iswalpha(wint_t c);`
	`int _ismbcalpha(unsigned int c);`
	Description
	Classifies an alphabetical character.
	isalpha is a macro that classifies ASCII-coded integer values by table lookup. The macro is affected by the current locale's LC_CTYPE category. For the default C locale, c is a letter (A to Z or a to z).
	You can make this macro available as a function by undefining (**#undef**) it.
	Return Value
	isalpha returns nonzero if c is a letter.
	__iscsymf returns true if and only if the argument c is... more (see page 775)

isascii, iswascii (see page 776)	**Header File**
	ctype.h, wctype.h
	Category
	Classification Routines
	Prototype
	`int isascii(int c);`
	`int iswascii(wint_t c);`
	Description
	Character classification macro.
	These functions depend on the LC_CTYPE
	isascii is a macro that classifies ASCII-coded integer values by table lookup. It is a predicate returning nonzero for true and 0 for false.
	isascii is defined on all integer values.
	Return Value
	isascii returns nonzero if c is in the range 0 to 127 (0x00-0x7F).
	iswascii returns nonzero if c is is a wide-character representation of an ASCII character.
	Each of these routines returns 0 if c does not satisfy the test condition.
	Example... more (see page 776)

iscntrl, iswcntrl (see page 777)	**Header File**
	ctype.h
	Category
	Classification Routines
	Prototype
	`int iscntrl(int c);`
	`int iswcntrl(wint_t c);`
	Description
	Tests for a control character.
	iscntrl is a macro that classifies ASCII-coded integer values by table lookup. The macro is affected by the current locale's LC_CTYPE category. For the default C locale, c is a delete character or control character (0x7F or 0x00 to 0x1F).
	You can make this macro available as a function by undefining (**#undef**) it.
	Return Value
	iscntrl returns nonzero if c is a delete character or ordinary control character.
	Example

isdigit, iswdigit, _ismbcdigit (see page 778)	**Header File**
	ctype.h, mbstring.h
	Category
	Classification Routines
	Prototype
	`int isdigit(int c);`
	`int iswdigit(wint_t c);`
	`int _ismbcdigit(unsigned int c);`
	Description
	Tests for decimal-digit character.
	isdigit is a macro that classifies ASCII-coded integer values by table lookup. The macro is affected by the current locale's LC_CTYPE category. For the default C locale, c is a digit (0 to 9).
	You can make this macro available as a function by undefining (**#undef**) it.
	Return Value
	isdigit returns nonzero if c is a digit.
	_ismbcdigit returns true if and only if the argument c is a single-byte representation of an ASCII digit.... more (see page 778)

isgraph, iswgraph, _ismbcgraph (see page 779)	**Header File**
	ctype.h, mbstring.h
	Category
	Classification Routines
	Prototype
	`int isgraph(int c);`
	`int iswgraph(wint_t c);`
	`int _ismbcgraph( unsigned int c);`
	Description
	Tests for printing character.
	isgraph is a macro that classifies ASCII-coded integer values by table lookup. The macro is affected by the current locale's LC_CTYPE category. For the default C locale, c is a printing character except blank space (' ').
	You can make this macro available as a function by undefining (**#undef**) it.
	Return Value
	isgraph returns nonzero if c is a printing character.
	Example

islower, iswlower, _ismbclower (see page 779)	**Header File**
	ctype.h, mbstring.h
	Category
	Classification Routines
	Prototype
	`int islower(int c);`
	`int iswlower(wint_t c);`
	`int _ismbclower(unsigned int c);`
	Description
	Tests for lowercase character.
	islower is a macro that classifies ASCII-coded integer values by table lookup. The macro is affected by the current locale's LC_CTYPE category. For the default C locale, c is a lowercase letter (a to z).
	You can make this macro available as a function by undefining (**#undef**) it.
	Return Value
	islower returns nonzero if c is a lowercase letter.
	Example

isprint, iswprint, _ismbcprint (see page 780)	**Header File**
	ctype.h, wctype.h, mbstring.h
	Category
	Classification Routines
	Prototype
	`int isprint(int c);`
	`int iswprint(wint_t c);`
	`int _ismbcprint(unsigned int c);`
	Description
	Tests for printing character.
	isprint is a macro that classifies ASCII-coded integer values by table lookup. The macro is affected by the current locale's LC_CTYPE category. For the default C locale, c is a printing character including the blank space (' ').
	You can make this macro available as a function by undefining (**#undef**) it.
	Return Value
	isprint returns nonzero if c is a printing character.
	Example

ispunct, iswpunct, _ismbcpunct (see page 781)	**Header File**
	ctype.h, wctype.h, mbstring.h
	Category
	Classification Routines
	Prototype
	`int ispunct(int c);`
	`int iswpunct(wint_t c);`
	`int _ismbcpunct(unsigned int c);`
	Description
	Tests for punctuation character.
	ispunct is a macro that classifies ASCII-coded integer values by table lookup. The macro is affected by the current locale's LC_CTYPE category. For the default C locale, c is any printing character that is neither an alphanumeric nor a blank space (' ').
	You can make this macro available as a function by undefining (**#undef**) it.
	Return Value
	ispunct returns nonzero if c is a punctuation character.
	Example

isspace, iswspace, _ismbcspace (see page 782)	**Header File**
	ctype.h, wctype.h, mbstring.h
	Category
	Classification Routines
	Prototype
	`int isspace(int c);`
	`int iswspace(wint_t c);`
	`int _ismbcspace(unsigned int c);`
	Description
	Tests for space character.
	isspace is a macro that classifies ASCII-coded integer values by table lookup. The macro is affected by the current locale's LC_CTYPE category.
	You can make this macro available as a function by undefining (**#undef**) it.
	Return Value
	isspace returns nonzero if c is a space, tab, carriage return, new line, vertical tab, formfeed (0x09 to 0x0D, 0x20), or any other locale-defined space character.
	Example

isupper, iswupper, _ismbcupper (see page 783)	**Header File**
	ctype.h, wctype.h, mbstring.h
	Category
	Classification Routines
	Prototype
	`int isupper(int c);`
	`int iswupper(wint_t c);`
	`int _ismbcupper(unsigned int c);`
	Description
	Tests for uppercase character.
	isupper is a macro that classifies ASCII-coded integer values by table lookup. The macro is affected by the current locale's LC_CTYPE category. For the default C locale, c is an uppercase letter (A to Z).
	You can make this macro available as a function by undefining (**#undef**) it.
	Return Value
	isupper returns nonzero if c is an uppercase letter.
	Example

isxdigit, iswxdigit (see page 784)	**Header File**
	ctype.h, wctype.h
	Category
	Classification Routines
	Prototype
	`int isxdigit(int c);`
	`int iswxdigit(wint_t c);`
	Description
	Tests for hexadecimal character.
	isxdigit is a macro that classifies ASCII-coded integer values by table lookup. The macro is affected by the current locale's LC_CTYPE category.
	You can make this macro available as a function by undefining (#undef) it.
	Return Value
	isxdigit returns nonzero if c is a hexadecimal digit (0 to 9, A to F, a to f) or any other hexadecimal digit defined by the locale.
	Example

toascii (see page 784)	**Header File** ctype.h **Category** Conversion Routines **Prototype** `int toascii(int c);` **Description** Translates characters to ASCII format. toascii is a macro that converts the integer c to ASCII by clearing all but the lower 7 bits; this gives a value in the range 0 to 127. **Return Value** toascii returns the converted value of c. **Portability**

tolower, _mbctolower, towlower (see page 785)	**Header File**
	ctype.h, mbstring.h
	Category
	Conversion Routines
	Prototype
	`int tolower(int ch);`
	`int towlower(wint_t ch); // Unicode version`
	`unsigned int _mbctolower(unsigned int c);`
	Description
	Translates characters to lowercase.
	tolower is a function that converts an integer ch (in the range EOF to 255) to its lowercase value (a to z; if it was uppercase, A to Z). All others are left unchanged.
	Return Value
	tolower returns the converted value of ch if it is uppercase; it returns all others unchanged.
	Example

toupper, _mbctoupper, towupper (see page 786)	**Header File**
	ctype.h, mbstring.h
	Category
	Conversion Routines
	Prototype
	`int toupper(int ch);`
	`int towupper(wint_t ch); // Unicode version`
	`unsigned int _mbctoupper(unsigned int c);`
	Description
	Translates characters to uppercase.
	toupper is a function that converts an integer ch (in the range EOF to 255) to its uppercase value (A to Z; if it was lowercase, a to z). All others are left unchanged.
	towupper is the Unicode version of toupper. It is available when Unicode is defined.
	Return Value
	toupper returns the converted value of ch if it is lowercase; it returns all others unchanged.
	Example

3.1.4.4.1 _ctype

Header File

ctype.h

Syntax

```
extern char _ctype[];
```

Description

_ctype is an array of character attribute information indexed by ASCII value + 1. Each entry is a set of bits describing the character. This array is used by isdigit, isprint, and so on.

3.1.4.4.2 _IS_xxx #defines

Header File

ctype.h

Description

Bit settings in the _ctype[] used by the is... character macros.

Name	Meaning
_IS_SP	Is space
_IS_DIG	Is digit
_IS_UPP	Is uppercase
_IS_LOW	Is lowercase
_IS_HEX	[A-F] or [a-f]
_IS_CTL	Control
_IS_PUN	Punctuation

3.1.4.4.3 _tolower

Header File

ctype.h

Category

Conversion Routines

Prototype

```
int _tolower(int ch);
```

Description

_tolower is a macro that does the same conversion as tolower, except that it should be used only when ch is known to be uppercase (AZ).

To use _tolower, you must include ctype.h.

Return Value

_tolower returns the converted value of ch if it is uppercase; otherwise, the result is undefined.

Example

```
#include <string.h>
#include <stdio.h>
#include <ctype.h>
int main(void)
{
   int length, i;
   char *string = "THIS IS A STRING.";
   length = strlen(string);
   for (i = 0; i < length; i++) {
       if ((string[i] >= 'A') && (string[i] <= 'Z')){
          string[i] = _tolower(string[i]);
       }
   }
   printf("%s\n",string);
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.4.4 _toupper

Header File

ctype.h

Category

Conversion Routines

Prototype

```
int _toupper(int ch);
```

Description

Translates characters to uppercase.

_toupper is a macro that does the same conversion as toupper, except that it should be used only when ch is known to be

lowercase (a to z).

To use _toupper, you must include ctype.h.

Return Value

_toupper returns the converted value of ch if it is lowercase; otherwise, the result is undefined.

Example

```
#include <string.h>
#include <stdio.h>
#include <ctype.h>
int main(void)
{
   int length, i;
   char *string = "this is a string.";
   length = strlen(string);
   for (i = 0; i < length; i++) {
      if ((string[i] >= 'a') && (string[i] <= 'z')){
         string[i] = _toupper(string[i]);
         }
   }
   printf("%s\n",string);
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.4.5 isalnum, __iscsym, iswalnum, _ismbcalnum

Header File

ctype.h, mbstring.h

Category

Classification Routines

Prototype

```
int isalnum(int c);
int __iscsym(int c);
int iswalnum(wint_t c);
int _ismbcalnum(unsigned int c);
```

Description

Tests for an alphanumeric character.

isalnum is a macro that classifies ASCII-coded integer values by table lookup. The macro is affected by the current locale's LC_CTYPE category. For the default C locale, c is a letter (A to Z or a to z) or a digit (0 to 9).

You can make this macro available as a function by undefining (**#undef**) it.

Return Value

It is a predicate returning nonzero for true and 0 for false.

isalnum returns nonzero if c is a letter or a digit.

__iscsym returns nonzero if c is a letter, underscore, or digit.

iswalnum returns nonzero if iswalpha or iswdigit return true for c.

_ismbcalnum returns true if and only if the argument c is a single-byte ASCII English letter.

Example

```
#include <stdio.h>
#include <ctype.h>
int main(void)
{
  char c = 'C';

  if (isalnum(c))
    printf("%c is alphanumeric\n",c);
  else
    printf("%c is not alphanumeric\n",c);
  return 0;
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
isalnum	+	+	+	+
__iscsym		+		
_ismbcalnum		+		
iswalnum		+	+	+

3.1.4.4.6 isalpha, __iscsymf, iswalpha, _ismbcalpha

Header File

ctype.h, mbstring.h

Category

Classification Routines

Prototype

```
int isalpha(int c);
int __iscsymf(int c);
int iswalpha(wint_t c);
int _ismbcalpha(unsigned int c);
```

Description

Classifies an alphabetical character.

isalpha is a macro that classifies ASCII-coded integer values by table lookup. The macro is affected by the current locale's LC_CTYPE category. For the default C locale, c is a letter (A to Z or a to z).

You can make this macro available as a function by undefining (**#undef**) it.

Return Value

isalpha returns nonzero if c is a letter.

__iscsymf returns true if and only if the argument c is a letter or an underscore.

iswalpha returns nonzero if c is a **wchar_t** in the character set defined by the implementation.

_ismbcalpha returns true if and only if the argument c is a single-byte ASCII English letter.

Example

```
#include <stdio.h>
#include <ctype.h>
int main(void)
{
  char c = 'C';

  if (isalpha(c))
    printf("%c is alphabetical\n",c);
  else
    printf("%c is not alphabetical\n",c);
  return 0;
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
isalpha	+	+	+	+
__iscsymf		+		
_ismbcalpha		+		
iswalpha		+	+	+

3.1.4.4.7 isascii, iswascii

Header File

ctype.h, wctype.h

Category

Classification Routines

Prototype

```
int isascii(int c);
int iswascii(wint_t c);
```

Description

Character classification macro.

These functions depend on the LC_CTYPE

isascii is a macro that classifies ASCII-coded integer values by table lookup. It is a predicate returning nonzero for true and 0 for false.

isascii is defined on all integer values.

Return Value

isascii returns nonzero if c is in the range 0 to 127 (0x00-0x7F).

iswascii returns nonzero if c is is a wide-character representation of an ASCII character.

Each of these routines returns 0 if c does not satisfy the test condition.

Example

```
#include <stdio.h>
#include <ctype.h>
#include <stdio.h>
int main(void)
{
  char c = 'C';
  if (isascii(c))
    printf("%c is ascii\n",c);
  else
    printf("%c is not ascii\n",c);
  return 0;
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
isascii		+		
iswascii		+		

3.1.4.4.8 iscntrl, iswcntrl

Header File

ctype.h

Category

Classification Routines

Prototype

```
int iscntrl(int c);
```

```
int iswcntrl(wint_t c);
```

Description

Tests for a control character.

iscntrl is a macro that classifies ASCII-coded integer values by table lookup. The macro is affected by the current locale's LC_CTYPE category. For the default C locale, c is a delete character or control character (0x7F or 0x00 to 0x1F).

You can make this macro available as a function by undefining (**#undef**) it.

Return Value

iscntrl returns nonzero if c is a delete character or ordinary control character.

Example

```
#include <stdio.h>
#include <ctype.h>
int main(void)
{
  char c = 'C';
  if (iscntrl(c))
    printf("%c is a control character\n",c);
  else
    printf("%c is not a control character\n",c);
  return 0;
```

```
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
iscntrl	+	+	+	+
iswcntrl		+	+	+

3.1.4.4.9 isdigit, iswdigit, _ismbcdigit

Header File

ctype.h, mbstring.h

Category

Classification Routines

Prototype

```
int isdigit(int c);
```

```
int iswdigit(wint_t c);
```

```
int _ismbcdigit(unsigned int c);
```

Description

Tests for decimal-digit character.

isdigit is a macro that classifies ASCII-coded integer values by table lookup. The macro is affected by the current locale's LC_CTYPE category. For the default C locale, c is a digit (0 to 9).

You can make this macro available as a function by undefining (**#undef**) it.

Return Value

isdigit returns nonzero if c is a digit.

_ismbcdigit returns true if and only if the argument c is a single-byte representation of an ASCII digit.

Example

```
#include <stdio.h>
#include <ctype.h>
int main(void)
{
  char c = 'C';
  if (isdigit(c))
    printf("%c is a digit\n",c);
  else
    printf("%c is not a digit\n",c);
  return 0;
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
isdigit	+	+	+	+
_ismbcdigit		+		
iswdigit		+	+	+

3.1.4.4.10 isgraph, iswgraph, _ismbcgraph

Header File

ctype.h, mbstring.h

Category

Classification Routines

Prototype

```
int isgraph(int c);
```

```
int iswgraph(wint_t c);
```

```
int _ismbcgraph( unsigned int c);
```

Description

Tests for printing character.

isgraph is a macro that classifies ASCII-coded integer values by table lookup. The macro is affected by the current locale's LC_CTYPE category. For the default C locale, c is a printing character except blank space (' ').

You can make this macro available as a function by undefining (**#undef**) it.

Return Value

isgraph returns nonzero if c is a printing character.

Example

```
#include <stdio.h>
#include <ctype.h>
int main(void)
{
  char c = 'C';
  if (isgraph(c))
    printf("%c is a graphic character\n",c);
  else
    printf("%c is not a graphic character\n",c);
  return 0;
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
isgraph	+	+	+	+
_ismbcgraph		+		
iswgraph		+	+	+

3.1.4.4.11 islower, iswlower, _ismbclower

Header File

ctype.h, mbstring.h

Category

Classification Routines

Prototype

```
int islower(int c);

int iswlower(wint_t c);

int _ismbclower(unsigned int c);
```

Description

Tests for lowercase character.

islower is a macro that classifies ASCII-coded integer values by table lookup. The macro is affected by the current locale's LC_CTYPE category. For the default C locale, c is a lowercase letter (a to z).

You can make this macro available as a function by undefining (**#undef**) it.

Return Value

islower returns nonzero if c is a lowercase letter.

Example

```
#include <stdio.h>
#include <ctype.h>
int main(void)
{
  char c = 'C';
  if (islower(c))
    printf("%c is a lowercase character\n",c);
  else
    printf("%c is not a lowercase character\n",c);
  return 0;
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
islower	+	+	+	+
_ismbclower		+		
iswlower		+	+	+

3.1.4.4.12 isprint, iswprint, _ismbcprint

Header File

ctype.h, wctype.h, mbstring.h

Category

Classification Routines

Prototype

```
int isprint(int c);

int iswprint(wint_t c);

int _ismbcprint(unsigned int c);
```

Description

Tests for printing character.

isprint is a macro that classifies ASCII-coded integer values by table lookup. The macro is affected by the current locale's LC_CTYPE category. For the default C locale, c is a printing character including the blank space (' ').

You can make this macro available as a function by undefining (**#undef**) it.

Return Value

isprint returns nonzero if c is a printing character.

Example

```
#include <stdio.h>
#include <ctype.h>
int main(void)
{
  char c = 'C';
  if (isprint(c))
    printf("%c is a printable character\n",c);
  else
    printf("%c is not a printable character\n",c);
  return 0;

3.1.4.4.13 ispunct, iswpunct, _ismbcpunct

Header File

ctype.h, wctype.h, mbstring.h

Category

Classification Routines

Prototype

```
int ispunct(int c);
```

```
int iswpunct(wint_t c);
```

```
int _ismbcpunct(unsigned int c);
```

Description

Tests for punctuation character.

ispunct is a macro that classifies ASCII-coded integer values by table lookup. The macro is affected by the current locale's LC_CTYPE category. For the default C locale, c is any printing character that is neither an alphanumeric nor a blank space (' ').

You can make this macro available as a function by undefining (**#undef**) it.

Return Value

ispunct returns nonzero if c is a punctuation character.

Example

```
#include <stdio.h>
#include <ctype.h>
int main(void)
{
  char c = 'C';
  if (ispunct(c))
    printf("%c is a punctuation character\n",c);
  else
    printf("%c is not a punctuation character\n",c);

  return 0;
}
```

Portability

3.1.4.4.14 isspace, iswspace, _ismbcspace

Header File

ctype.h, wctype.h, mbstring.h

Category

Classification Routines

Prototype

```
int isspace(int c);
```

```
int iswspace(wint_t c);
```

```
int _ismbcspace(unsigned int c);
```

Description

Tests for space character.

isspace is a macro that classifies ASCII-coded integer values by table lookup. The macro is affected by the current locale's LC_CTYPE category.

You can make this macro available as a function by undefining (**#undef**) it.

Return Value

isspace returns nonzero if c is a space, tab, carriage return, new line, vertical tab, formfeed (0x09 to 0x0D, 0x20), or any other locale-defined space character.

Example

```
#include <stdio.h>
#include <ctype.h>
int main(void)
{
  char c = 'C';
  if (isspace(c))
    printf("%c is white space\n",c);
  else
    printf("%c is not white space\n",c);
```

```
  return 0;
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
isspace	+	+	+	+
_ismbcspace		+		
iswspace		+	+	+

3.1.4.4.15 isupper, iswupper, _ismbcupper

Header File

ctype.h, wctype.h, mbstring.h

Category

Classification Routines

Prototype

```
int isupper(int c);
```

```
int iswupper(wint_t c);
```

```
int _ismbcupper(unsigned int c);
```

Description

Tests for uppercase character.

isupper is a macro that classifies ASCII-coded integer values by table lookup. The macro is affected by the current locale's LC_CTYPE category. For the default C locale, c is an uppercase letter (A to Z).

You can make this macro available as a function by undefining (**#undef**) it.

Return Value

isupper returns nonzero if c is an uppercase letter.

Example

```
#include <stdio.h>
#include <ctype.h>
int main(void)
{
  char c = 'C';
  if (isupper(c))
    printf("%c is an uppercase character\n",c);
  else
    printf("%c is not an uppercase character\n",c);
  return 0;
}
```

Portability

3.1.4.4.16 isxdigit, iswxdigit

Header File

ctype.h, wctype.h

Category

Classification Routines

Prototype

```
int isxdigit(int c);
```

```
int iswxdigit(wint_t c);
```

Description

Tests for hexadecimal character.

isxdigit is a macro that classifies ASCII-coded integer values by table lookup. The macro is affected by the current locale's LC_CTYPE category.

You can make this macro available as a function by undefining (#undef) it.

Return Value

isxdigit returns nonzero if c is a hexadecimal digit (0 to 9, A to F, a to f) or any other hexadecimal digit defined by the locale.

Example

```
#include <stdio.h>
#include <ctype.h>
int main(void)
{
  char c = 'C';
  if (isxdigit(c))
    printf("%c is a hexadecimal digit\n",c);
  else
    printf("%c is not a hexadecimal digit\n",c);
  return 0;
}
```

iswxdigit		+	+	+

3.1.4.4.17 toascii

Header File

ctype.h

Category

Conversion Routines

Prototype

```
int toascii(int c);
```

Description

Translates characters to ASCII format.

toascii is a macro that converts the integer c to ASCII by clearing all but the lower 7 bits; this gives a value in the range 0 to 127.

Return Value

toascii returns the converted value of c.

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.4.18 tolower, _mbctolower, towlower

Header File

ctype.h, mbstring.h

Category

Conversion Routines

Prototype

```
int tolower(int ch);
```

```
int towlower(wint_t ch); // Unicode version
```

```
unsigned int _mbctolower(unsigned int c);
```

Description

Translates characters to lowercase.

tolower is a function that converts an integer ch (in the range EOF to 255) to its lowercase value (a to z; if it was uppercase, A to Z). All others are left unchanged.

Return Value

tolower returns the converted value of ch if it is uppercase; it returns all others unchanged.

Example

```
#include <string.h>
#include <stdio.h>
#include <ctype.h>
int main(void)
{
   int length, i;
   char *string = "THIS IS A STRING";
   length = strlen(string);
   for (i=0; i<length; i++)
   {
       string[i] = tolower(string[i]);
   }
   printf("%s\n",string);
   return 0;
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++

3.1.4.4.19 toupper, _mbctoupper, towupper

Header File

ctype.h, mbstring.h

Category

Conversion Routines

Prototype

```
int toupper(int ch);
int towupper(wint_t ch); // Unicode version
unsigned int _mbctoupper(unsigned int c);
```

Description

Translates characters to uppercase.

toupper is a function that converts an integer ch (in the range EOF to 255) to its uppercase value (A to Z; if it was lowercase, a to z). All others are left unchanged.

towupper is the Unicode version of toupper. It is available when Unicode is defined.

Return Value

toupper returns the converted value of ch if it is lowercase; it returns all others unchanged.

Example

```
#include <string.h>
#include <stdio.h>
#include <ctype.h>
int main(void)
{
   int length, i;
   char *string = "this is a string";
   length = strlen(string);
   for (i=0; i<length; i++)
   {
      string[i] = toupper(string[i]);
   }
   printf("%s\n",string);
   return 0;
}
```

3.1.4.5 delayimp.h

The following functions, macros, and classes are provided in `delayimp.h`:

Topics

Name	Description

__pfnDliNotifyHook, __pfnDliFailureHook (see page 787)	**Header File**
	delayimp.h
	Category
	Delay load hook notification Routines
	Prototype
	`typedef FARPROC (WINAPI *DelayedLoadHook)(dliNotification dliNotify,`
	`DelayLoadInfo * pdli);`
	Description
	The delay load mechanism provides two hooks for you to modify the runtime behavior of a delay loaded DLL. By writing your own hook functions using the function signature below and assigning this to the two hooks you can modify the delay load process.
	DelayLoadProc structure
	`typedef struct DelayLoadProc`
	`{`
	`BOOL fImportByName;`
	`union`
	`{`
	`LPCSTR szProcName;`
	`DWORD dwOrdinal;`
	`};`
	`} DelayLoadProc;`
	ImgDelayDescr structure
	`typedef struct ImgDelayDescr`
	`{`
	`DWORD grAttrs; /* attributes */`
	`LPCSTR szName; /* pointer to dll name */`
	`HMODULE...  more (see page 787)`

__FUnloadDelayLoadedDLL (see page 790)	**Header File** delayimp.h **Prototype** BOOL WINAPI __FUnloadDelayLoadedDLL(LPCSTR szDll); **Description** Unloads a delay loaded DLL. szDll is pointer to a name to unload, or NULL to unload all the delay load DLLs in the list. **Return Value** On successful completion __FUnloadDelayLoadedDLL returns **true**. On error it returns **false**.

3.1.4.5.1 __pfnDliNotifyHook, __pfnDliFailureHook

Header File

delayimp.h

Category

Delay load hook notification Routines

Prototype

```
typedef FARPROC (WINAPI *DelayedLoadHook)(dliNotification dliNotify,
DelayLoadInfo * pdli);
```

Description

The delay load mechanism provides two hooks for you to modify the runtime behavior of a delay loaded DLL. By writing your own hook functions using the function signature below and assigning this to the two hooks you can modify the delay load process.

DelayLoadProc structure

```
typedef struct DelayLoadProc
{
BOOL fImportByName;
union
{
LPCSTR szProcName;
DWORD dwOrdinal;
};
} DelayLoadProc;
```

ImgDelayDescr structure

```
typedef struct ImgDelayDescr
{
DWORD grAttrs; /* attributes */
LPCSTR szName; /* pointer to dll name */
HMODULE hmod; /* address of module handle */
IMAGE_THUNK_DATA * pIAT; /* address of the IAT */
IMAGE_THUNK_DATA * pINT; /* address of the INT */
IMAGE_THUNK_DATA * pBoundIAT; /* address of the optional bound IAT */
IMAGE_THUNK_DATA * pUnloadIAT; /* address of optional copy of
original IAT */
DWORD dwTimeStamp; /* 0 if not bound, */
/* O.W. date/time stamp of DLL bound
to (Old BIND) */
} ImgDelayDescr;
```

DelayLoadInfo structure

```
typedef struct DelayLoadInfo
{
DWORD cb; /* size of structure */
const ImgDelayDescr * pidd; /* raw form of data (everything is
there) */
FARPROC * ppfn; /* points to address of function to
load */
```

```
LPCSTR szDll; /* name of dll */
DelayLoadProc dlp; /* name or ordinal of procedure */
HMODULE hmodCur; /* the hInstance of the library we
have loaded */
FARPROC pfnCur; /* the actual function that will be
called */
DWORD dwLastError;/* error received (if an error
notification) */
} DelayLoadInfo, *PDelayLoadInfo;
```

Delay load import hook notifications

The following structure is the enumerations that are defined for the hook notification events:

```
typedef enum
{
dliNoteStartProcessing, /* used to bypass or note helper only */
dliNotePreLoadLibrary, /* called just before LoadLibrary, can */
/* override w/ new HMODULE return val */
dliNotePreGetProcAddress, /* called just before GetProcAddress, can */
/* override w/ new FARPROC return value */
dliFailLoadLibrary, /* failed to load library, fix it by */
/* returning a valid HMODULE */
dliFailGetProcAddress, /* failed to get proc address, fix it by */
/* returning a valid FARPROC */
dliNoteEndProcessing, /* called after all processing is done, */
/* no bypass possible at this point */
/* except by longjmp(), throw(), or
RaiseException. */
} dliNotification;
```

Hook pointers

The “notify hook” gets called for every call to the delay load helper. This allows a user to hook every call and skip the delay load helper entirely.

```
extern DelayedLoadHook _EXPDATA __pfnDliNotifyHook;
dliNotify ==
{
dliNoteStartProcessing |
dliNotePreLoadLibrary |
dliNotePreGetProcAddress |
dliNoteEndProcessing
```

```
}
```

Note: The “failure” hook is assigned to:

```
extern DelayedLoadHook _EXPDATA __pfnDliFailureHook;
```

This hook is called with the following notification flags:

```
dliNotify ==
{
dliFailLoadLibrary |
dliFailGetProcAddress
}
```

For further information on when this notify eventsd occur during the delay load process, please see delayhlp.c

3.1.4.5.2 __FUnloadDelayLoadedDLL

Header File

delayimp.h

Prototype

```
BOOL WINAPI __FUnloadDelayLoadedDLL(LPCSTR szDll);
```

Description

Unloads a delay loaded DLL.

szDll is pointer to a name to unload, or NULL to unload all the delay load DLLs in the list.

Return Value

On successful completion __FUnloadDelayLoadedDLL returns **true**.

On error it returns **false**.

3.1.4.6 direct.h

The following functions, macros, and classes are provided in `direct.h`:

Topics

Name	Description
_chdrive (see page 791)	**Header File** direct.h **Category** Directory Control Routines **Prototype** `int _chdrive(int drive);` **Description** Sets current disk drive. _chdrive sets the current drive to the one associated with drive: 1 for A, 2 for B, 3 for C, and so on. This function changes the current drive of the parent process. **Return Value** _chdrive returns 0 if the current drive was changed successfully; otherwise, it returns -1. **Example**

_getdcwd, _wgetdcwd (see page 791)	**Header File**
	direct.h
	Category
	Directory Control Routines
	Prototype
	`char * _getdcwd(int drive, char *buffer, int buflen);`
	`wchar_t * _wgetdcwd(int drive, wchar_t *buffer, int buflen);`
	Description
	Gets current directory for specified drive.
	_getdcwd gets the full path name of the working directory of the specified drive (including the drive name), up to buflen bytes long, and stores it in buffer. If the full path name length (including the null-terminator) is longer than buflen, an error occurs. The drive is 0 for the default drive, 1=A, 2=B, and so on.
	If the working directory is the root directory, the terminating character for... more (see page 791)

3.1.4.6.1 _chdrive

Header File

direct.h

Category

Directory Control Routines

Prototype

```
int _chdrive(int drive);
```

Description

Sets current disk drive.

_chdrive sets the current drive to the one associated with drive: 1 for A, 2 for B, 3 for C, and so on.

This function changes the current drive of the parent process.

Return Value

_chdrive returns 0 if the current drive was changed successfully; otherwise, it returns -1.

Example

```
 #include <stdio.h>
#include <direct.h>
int main(void)
{
  if (_chdrive(3) == 0)
    printf("Successfully changed to drive C:\n");
  else
    printf("Cannot change to drive C:\n");
  return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.6.2 _getdcwd, _wgetdcwd

Header File

direct.h

Category

Directory Control Routines

Prototype

```
char * _getdcwd(int drive, char *buffer, int buflen);
```

```
wchar_t * _wgetdcwd(int drive, wchar_t *buffer, int buflen);
```

Description

Gets current directory for specified drive.

_getdcwd gets the full path name of the working directory of the specified drive (including the drive name), up to buflen bytes long, and stores it in buffer. If the full path name length (including the null-terminator) is longer than buflen, an error occurs. The drive is 0 for the default drive, 1=A, 2=B, and so on.

If the working directory is the root directory, the terminating character for the full path is a backslash. If the working directory is a subdirectory, there is no terminating backslash after the subdirectory name.

If buffer is NULL, _getdcwd allocates a buffer at least buflen bytes long. You can later free the allocated buffer by passing the _getdcwd return value to the free function.

Return Value

If successful, _getdcwd returns a pointer to the buffer containing the current directory for the specified drive.

Otherwise it returns NULL, and sets the global variable errno to one of the following values:

ENOMEM	Not enough memory to allocate a buffer (buffer is NULL)
ERANGE	Directory name longer than buflen (buffer is not NULL)

Example

```
#include <direct.h>
#include <stdio.h>
char buf[65];
void main()
{
  if (_getdcwd(3, buf, sizeof(buf)) == NULL)
    perror("Unable to get current directory of drive C");
  else
    printf("Current directory of drive C is %s\n",buf);
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
_getdcwd		+		
_wgetdcwd		NT only		

3.1.4.7 dirent.h

The following functions, macros, and classes are provided in `dirent.h`:

Topics

Name	Description

closedir, wclosedir (see page 794)	**Header File**
	dirent.h
	Category
	Directory Control Routines
	Prototype
	`void closedir(DIR *dirp);`
	`void wclosedir(wDIR *dirp);`
	Description
	Closes a directory stream.
	closedir is available on POSIX-compliant UNIX systems.
	The closedir function closes the directory stream dirp, which must have been opened by a previous call to opendir. After the stream is closed, dirp no longer points to a valid directory stream.
	wclosedir is the Unicode version of closedir.
	Return Value
	If closedir is successful, it returns 0. Otherwise, closedir returns -1 and sets the global variable errno to

opendir, wopendir (see page 795)	**Header File**
	dirent.h
	Category
	Directory Control Routines
	Prototype
	`DIR *opendir(const char *dirname);`
	`wDIR *wopendir(const wchar_t *dirname);`
	Description
	Opens a directory stream for reading.
	opendir is available on POSIX-compliant UNIX systems.
	The opendir function opens a directory stream for reading. The name of the directory to read is dirname. The stream is set to read the first entry in the directory.
	A directory stream is represented by the DIR structure, defined in dirent.h. This structure contains no user-accessible fields. Multiple directory streams can be opened and read simultaneously. Directory entries can be created or deleted while a directory stream is being... more (see page 795)

readdir, wreaddir (see page 796)	**Header File**
	dirent.h
	Category
	Directory Control Routines
	Prototype
	`struct dirent *readdir(DIR *dirp);`
	`struct wdirent *wreaddir(wDIR *dirp)`
	Description
	Reads the current entry from a directory stream.
	readdir is available on POSIX-compliant UNIX systems.
	The readdir function reads the current directory entry in the directory stream pointed to by dirp. The directory stream is advanced to the next entry.
	The readdir function returns a pointer to a **dirent** structure that is overwritten by each call to the function on the same directory stream. The structure is not overwritten by a readdir call on a different directory stream.
	The **dirent** structure corresponds to... more (see page 796)

	dirent.h
	Category
	Directory Control Routines
	Prototype
	`void rewinddir(DIR *dirp);`
	`void wrewinddir(wDIR *dirp);`
	Description
	Resets a directory stream to the first entry.
	rewinddir is available on POSIX-compliant UNIX systems.
	The rewinddir function repositions the directory stream dirp at the first entry in the directory. It also ensures that the directory stream accurately reflects any directory entries that might have been created or deleted since the last opendir or rewinddir on that directory stream.
	wrewinddir is the Unicode version of rewinddir.
	Return Value
	None.
	Example

3.1.4.7.1 closedir, wclosedir

Header File

dirent.h

Category

Directory Control Routines

Prototype

```
void closedir(DIR *dirp);
```

```
void wclosedir(wDIR *dirp);
```

Description

Closes a directory stream.

closedir is available on POSIX-compliant UNIX systems.

The closedir function closes the directory stream dirp, which must have been opened by a previous call to opendir. After the stream is closed, dirp no longer points to a valid directory stream.

wclosedir is the Unicode version of closedir.

Return Value

If closedir is successful, it returns 0. Otherwise, closedir returns -1 and sets the global variable errno to

EBADF	The dirp argument does not point to a valid open directory stream

Example

```
/* opendir.c - test opendir(), readdir(), closedir() */

#include <dirent.h>
#include <stdio.h>
#include <stdlib.h>

void scandir(char *dirname)
{
   DIR *dir;
   struct dirent *ent;
```

```
    printf("First pass on '%s':\n",dirname);
    if ((dir = opendir(dirname)) == NULL)
    {
      perror("Unable to open directory");
      exit(1);
    }
    while ((ent = readdir(dir)) != NULL)
      printf("%s\n",ent->d_name);

    printf("Second pass on '%s':\n",dirname);
    rewinddir(dir);
    while ((ent = readdir(dir)) != NULL)
      printf("%s\n",ent->d_name);
    if (closedir(dir) != 0)
      perror("Unable to close directory");
}

void main(int argc,char *argv[])
{
    if (argc != 2)
    {
      printf("usage: opendir dirname\n");
      exit(1);
    }
    scandir(argv[1]);
    exit(0);
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
+	+		

3.1.4.7.2 opendir, wopendir

Header File

dirent.h

Category

Directory Control Routines

Prototype

```
DIR *opendir(const char *dirname);
```

```
wDIR *wopendir(const wchar_t *dirname);
```

Description

Opens a directory stream for reading.

opendir is available on POSIX-compliant UNIX systems.

The opendir function opens a directory stream for reading. The name of the directory to read is dirname. The stream is set to read the first entry in the directory.

A directory stream is represented by the DIR structure, defined in dirent.h. This structure contains no user-accessible fields. Multiple directory streams can be opened and read simultaneously. Directory entries can be created or deleted while a directory stream is being read.

Use the readdir function to read successive entries from a directory stream. Use the closedir function to remove a directory

stream when it is no longer needed.

Return Value

On success, opendir returns a pointer to a directory stream that can be used in calls to readdir, rewinddir, and closedir.

On error (If the directory cannot be opened), the functino returns NULL and sets the global variable errno to

ENOENT	The directory does not exist
ENOMEM	Not enough memory to allocate a DIR object

Example

```
 /* opendir.c - test opendir(), readdir(), closedir() */

#include <dirent.h>
#include <stdio.h>
#include <stdlib.h>

void scandir(char *dirname)
{
   DIR *dir;
   struct dirent *ent;

   printf("First pass on '%s':\n",dirname);
   if ((dir = opendir(dirname)) == NULL)
   {
     perror("Unable to open directory");
     exit(1);
   }
   while ((ent = readdir(dir)) != NULL)
     printf("%s\n",ent->d_name);

   printf("Second pass on '%s':\n",dirname);
   rewinddir(dir);
   while ((ent = readdir(dir)) != NULL)
     printf("%s\n",ent->d_name);
   if (closedir(dir) != 0)
     perror("Unable to close directory");
}

void main(int argc,char *argv[])
{
   if (argc != 2)
   {
     printf("usage: opendir dirname\n");
     exit(1);
   }
   scandir(argv[1]);
   exit(0);
}
```

opendir	+	+		
wopendir				

3.1.4.7.3 readdir, wreaddir

Header File

dirent.h

Category

Directory Control Routines

Prototype

```
struct dirent *readdir(DIR *dirp);
struct wdirent *wreaddir(wDIR *dirp)
```

Description

Reads the current entry from a directory stream.

readdir is available on POSIX-compliant UNIX systems.

The readdir function reads the current directory entry in the directory stream pointed to by dirp. The directory stream is advanced to the next entry.

The readdir function returns a pointer to a **dirent** structure that is overwritten by each call to the function on the same directory stream. The structure is not overwritten by a readdir call on a different directory stream.

The **dirent** structure corresponds to a single directory entry. It is defined in dirent.h and contains (in addition to other non-accessible members) the following member:

char d_name[];

where d_name is an array of characters containing the null-terminated file name for the current directory entry. The size of the array is indeterminate; use strlen to determine the length of the file name.

All valid directory entries are returned, including subdirectories, “.” and “..” entries, system files, hidden files, and volume labels. Unused or deleted directory entries are skipped.

A directory entry can be created or deleted while a directory stream is being read, but readdir might or might not return the affected directory entry. Rewinding the directory with rewinddir or reopening it with opendir ensures that readdir will reflect the current state of the directory.

The wreaddir function is the Unicode version of readdir. It uses the **wdirent** structure but otherwise is similar to readdir.

Return Value

On success, readdir returns a pointer to the current directory entry for the directory stream.

If the end of the directory has been reached, or dirp does not refer to an open directory stream, readdir returns NULL.

Portability

	POSIX	Win32	ANSI C	ANSI C++
readdir	+	+		
wreaddir		+		

3.1.4.7.4 rewinddir, wrewinddir

Header File

dirent.h

Category

Directory Control Routines

Prototype

```
void rewinddir(DIR *dirp);

void wrewinddir(wDIR *dirp);
```

Description

Resets a directory stream to the first entry.

rewinddir is available on POSIX-compliant UNIX systems.

The rewinddir function repositions the directory stream dirp at the first entry in the directory. It also ensures that the directory stream accurately reflects any directory entries that might have been created or deleted since the last opendir or rewinddir on that directory stream.

wrewinddir is the Unicode version of rewinddir.

Return Value

None.

Example

```
/* opendir.c - test opendir(), readdir(), closedir() */

#include <dirent.h>
#include <stdio.h>
#include <stdlib.h>

void scandir(char *dirname)
{
   DIR *dir;
   struct dirent *ent;

   printf("First pass on '%s':\n",dirname);
   if ((dir = opendir(dirname)) == NULL)
   {
     perror("Unable to open directory");
     exit(1);
   }
   while ((ent = readdir(dir)) != NULL)
     printf("%s\n",ent->d_name);

   printf("Second pass on '%s':\n",dirname);
   rewinddir(dir);
   while ((ent = readdir(dir)) != NULL)
     printf("%s\n",ent->d_name);
   if (closedir(dir) != 0)
     perror("Unable to close directory");
 }

 void main(int argc,char *argv[])
 {
   if (argc != 2)
   {
     printf("usage: opendir dirname\n");
     exit(1);
   }
   scandir(argv[1]);
   exit(0);
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
rewind	+	+		
wrewinddir		+		

3.1.4.8 dir.h

The following functions, macros, and classes are provided in `dir.h`:

Topics

Name	Description

chdir (see page 803)	**Header File**
	dir.h
	Category
	Directory Control Routines
	Prototype
	`int chdir(const char *path);`
	`int _wchdir(const wchar_t *path);`
	Description
	Changes current directory.
	chdir causes the directory specified by path to become the current working directory; path must specify an existing directory.
	A drive can also be specified in the path argument, such as
	`chdir("a:\\BC")`
	but this method changes only the current directory on that drive; it does not change the active drive.
	• Under Windows, only the current process is affected.
	Return Value
	Upon successful completion, chdir returns a value of 0. Otherwise, it returns a value of -1, and the global variable... more (see page 803)

MAXxxxx #defines (fnsplit) (see page 804)	**Header File** dir.h **Description** These symbols define the maximum number of characters in a file specification for fnsplit (including room for a terminating NULL).

findclose, _wfindclose (see page 804)	**Header File**
	dir.h
	Category
	Directory Control Routines
	Prototype
	`int findclose(struct ffblk *ffblk );`
	`int _wfindclose(struct _wffblk *ffblk );`
	Description
	findclose closes any handles and frees up any dynamic memory associated with previous calls to findfirst and findnext.
	Return Value
	findclose returns 0 on successfully closing the handle. On failure:
	• -1 is returned
	• errno is set to

findfirst, _wfindfirst (see page 805)	**Header File**
	dir.h
	Category
	Directory Control Routines
	Prototype
	`int findfirst(const char *pathname, struct ffblk *ffblk, int attrib);`
	`int _wfindfirst( const wchar_t *pathname, struct _wffblk *ffblk, int attrib);`
	Description
	Searches a disk directory.
	findfirst begins a search of a disk directory for files specified by attributes or wildcards.
	pathname is a string with an optional drive specifier path and file name of the file to be found. Only the file name portion can contain wildcard match characters (such as ? or *). If a matching file is found the ffblk structure is filled with the file-directory information.
	When Unicode is defined,... more (see page 805)

findnext, _wfindnext (see page 807)	**Header File**
	dir.h
	Category
	Directory Control Routines
	Prototype
	`int findnext(struct ffblk *ffblk );`
	`int _wfindnext(struct _wffblk *ffblk );`
	Description
	Continues findfirst search.
	findnext is used to fetch subsequent files that match the pathname given in findfirst. ffblk is the same block filled in by the findfirst call. This block contains necessary information for continuing the search. One file name for each call to findnext will be returned until no more files are found in the directory matching the pathname.
	Return Value
	findnext returns 0 on successfully finding a file matching the search pathname. When no more files can be found... more (see page 807)

fnmerge, _wfnmerge (see page 808)	**Header File**
	dir.h
	Category
	Directory Control Routines
	Prototype
	`void fnmerge(char *path, const char *drive, const char *dir, const char *name, const char *ext);`
	`void _wfnmerge(wchar_t *path, const wchar_t *drive, const wchar_t *dir, const wchar_t *name, const wchar_t *ext );`
	Description
	Builds a path from component parts.
	fnmerge makes a path name from its components. The new path name is
	`X:\DIR\SUBDIR\NAME.EXT`
	where:

fnsplit, _wfnsplit (see page 810)	**Header File**
	dir.h
	Category
	Directory Control Routines
	Prototype
	`int fnsplit(const char *path, char *drive, char *dir, char *name, char *ext);`
	`int _wfnsplit(const wchar_t *path, wchar_t *drive, wchar_t *dir, wchar_t *name, wchar_t *ext );`
	Description
	Splits a full path name into its components.
	fnsplit takes a file's full path name (path) as a string in the form X:\DIR\SUBDIR\NAME.EXT and splits path into its four components. It then stores those components in the strings pointed to by drive, dir, name, and ext. All five components must be passed but any of them can be a null which means the corresponding component will... more (see page 810)

Bit Definitions for fnsplit (see page 811)	**Header File** dir.h **Description** Bit definitions returned from fnsplit to identify which pieces of a file name were found during the split.

getcurdir, _wgetcurdir (see page 811)	**Header File**
	dir.h
	Category
	Directory Control Routines
	Prototype
	`int getcurdir(int drive, char *directory);`
	`int _wgetcurdir(int drive, wchar_t *directory );`
	Description
	Gets current directory for specified drive.
	getcurdir gets the name of the current working directory for the drive indicated by drive. drive specifies a drive number (0 for default, 1 for A, and so on). directory points to an area of memory of length MAXDIR where the null-terminated directory name will be placed. The name does not contain the drive specification and does not begin with a backslash.
	Return Value
	getcurdir returns 0 on success or -1 in the event... more (see page 811)

getcwd, _wgetcwd (see page 812)	**Header File**
	dir.h
	Category
	Directory Control Routines
	Prototype
	`char *getcwd(char *buf, int buflen);`
	`wchar_t *_wgetcwd(wchar_t *buf, int buflen);`
	Description
	Gets current working directory.
	getcwd gets the full path name (including the drive) of the current working directory, up to buflen bytes long and stores it in buf. If the full path name length (including the null terminator) is longer than buflen bytes, an error occurs.
	If buf is NULL, a buffer buflen bytes long is allocated for you with malloc. You can later free the allocated buffer by passing the return value of getcwd to the function free.
	Return Value... more (see page 812)

getdisk, setdisk (see page 813)	**Header File**
	dir.h
	Category
	Directory Control Routines
	Prototype
	`int getdisk(void);`
	`int setdisk(int drive);`
	Description
	Gets or sets the current drive number.
	getdisk gets the current drive number. It returns an integer: 0 for A, 1 for B, 2 for C, and so on.
	setdisk sets the current drive to the one associated with drive: 0 for A, 1 for B, 2 for C, and so on.
	The setdisk function changes the current drive of the parent process.
	Return Value
	getdisk returns the current drive number. setdisk returns the total number of drives available.
	Example

mkdir, _wmkdir (see page 814)	**Header File**
	dir.h
	Category
	Directory Control Routines
	Prototype
	`int mkdir(const char *path);`
	`int _wmkdir(const wchar_t *path);`
	Description
	Creates a directory.
	mkdir is available on UNIX, though it then takes an additional parameter.
	mkdir creates a new directory from the given path name path.
	Return Value
	mkdir returns the value 0 if the new directory was created.
	A return value of -1 indicates an error, and the global variable errno is set to one of the following values:

_mktemp, _wmktemp (see page 815)	**Header File**
	dir.h
	Category
	Directory Control Routines
	Prototype
	`char *_mktemp(char *template);`
	`wchar_t *_wmktemp(wchar_t *template);`
	Description
	Makes a unique file name.
	_mktemp replaces the string pointed to by template with a unique file name and returns template.
	template should be a null-terminated string with six trailing Xs. These Xs are replaced with a unique collection of letters plus a period, so that there are two letters, a period, and three suffix letters in the new file name.
	Starting with AA.AAA, the new file name is assigned by looking up the name on the disk and avoiding pre-existing names of the same... more (see page 815)

_rmdir, _wrmdir (see page 816)	**Header File**
	dir.h
	Category
	Directory Control Routines
	Prototype
	`int _rmdir(const char *path);`
	`int _wrmdir(const wchar_t *path);`
	Description
	Removes a directory.
	_rmdir deletes the directory whose path is given by path. The directory named by path
	• must be empty
	• must not be the current working directory
	• must not be the root directory
	Return Value
	_rmdir returns 0 if the directory is successfully deleted. A return value of -1 indicates an error, and the global variable errno is set to one of the following values:

searchpath, wsearchpath (see page 817)	**Header File**
	dir.h
	Category
	Miscellaneous Routines
	Prototype
	`char *searchpath(const char *file);`
	`wchar_t *wsearchpath( const wchar_t *file );`
	Description
	Searches the operating system path for a file.
	searchpath attempts to locate file, searching along the operating system path, which is the PATH=... string in the environment. A pointer to the complete path-name string is returned as the function value.
	searchpath searches for the file in the current directory of the current drive first. If the file is not found there, the PATH environment variable is fetched, and each directory in the path is searched in turn until the file is found,... more (see page 817)

3.1.4.8.1 chdir

Header File

dir.h

Category

Directory Control Routines

Prototype

```
int chdir(const char *path);
```

```
int _wchdir(const wchar_t *path);
```

Description

Changes current directory.

chdir causes the directory specified by path to become the current working directory; path must specify an existing directory.

A drive can also be specified in the path argument, such as

```
chdir("a:\\BC")
```

but this method changes only the current directory on that drive; it does not change the active drive.

- Under Windows, only the current process is affected.

Return Value

Upon successful completion, chdir returns a value of 0. Otherwise, it returns a value of -1, and the global variable errno is set to

ENOENT	Path or file name not found

Example

```
#include <stdio.h>
#include <stdlib.h>
#include <dir.h>
char old_dir[MAXDIR];
char new_dir[MAXDIR];
int main(void)
{
   if (getcurdir(0, old_dir))
   {
      perror("getcurdir()");
      exit(1);
```

```
    }
    printf("Current directory is: \\%s\n", old_dir);
    if (chdir("\\"))
    {
       perror("chdir()");
       exit(1);
    }
    if (getcurdir(0, new_dir))
    {
       perror("getcurdir()");
       exit(1);
    }
    printf("Current directory is now: \\%s\n", new_dir);
    printf("\nChanging back to original directory: \\%s\n", old_dir);
    if (chdir(old_dir))
    {
       perror("chdir()");
       exit(1);
    }
    return 0;
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
chdir	+	+		
_wchdir		NT only		

3.1.4.8.2 MAXxxxx #defines (fnsplit)

Header File

dir.h

Description

These symbols define the maximum number of characters in a file specification for fnsplit (including room for a terminating NULL).

Name	Meaning
MAXPATH	Complete file name with path
MAXDRIVE	Disk drive (e.g., "A:")
MAXDIR	File subdirectory specification
MAXFILE	File name without extension
MAXEXT	File extension

3.1.4.8.3 findclose, _wfindclose

Header File

dir.h

Category

Directory Control Routines

Prototype

```
int findclose(struct ffblk *ffblk );
int _wfindclose(struct _wffblk *ffblk );
```

Description

findclose closes any handles and frees up any dynamic memory associated with previous calls to findfirst and findnext.

Return Value

findclose returns 0 on successfully closing the handle. On failure:

- -1 is returned
- errno is set to

EINVDAT	Invalid data

Portability

	POSIX	Win32	ANSI C	ANSI C++
findclose		+		
_wfindclose		NT only		

See Also

findfirst (see page 805)

findnext (see page 807)

3.1.4.8.4 findfirst, _wfindfirst

Header File

dir.h

Category

Directory Control Routines

Prototype

```
int findfirst(const char *pathname, struct ffblk *ffblk, int attrib);
int _wfindfirst( const wchar_t *pathname, struct _wffblk *ffblk, int attrib);
```

Description

Searches a disk directory.

findfirst begins a search of a disk directory for files specified by attributes or wildcards.

pathname is a string with an optional drive specifier path and file name of the file to be found. Only the file name portion can contain wildcard match characters (such as ? or *). If a matching file is found the ffblk structure is filled with the file-directory information.

When Unicode is defined, the _wfindfirst function uses the following _wffblk structure.

```
struct _wffblk {
```

```
long ff_reserved;
long ff_fsize;
unsigned long ff_attrib;
unsigned short ff_ftime;
unsigned short ff_fdate;
wchar_t ff_name[256];
};
```

For Win32, the format of the structure ffblk is as follows:

```
struct ffblk {
long ff_reserved;
long ff_fsize; /* file size */
unsigned long ff_attrib; /* attribute found */
unsigned short ff_ftime; /* file time */
unsigned short ff_fdate; /* file date */
char ff_name[256]; /* found file name */
};
```

attrib is a file-attribute byte used in selecting eligible files for the search. attrib should be selected from the following constants defined in dos.h:

FA_RDONLY	Read-only attribute
FA_HIDDEN	Hidden file
FA_SYSTEM	System file
FA_LABEL	Volume label
FA_DIREC	Directory
FA_ARCH	Archive

A combination of constants can be OR'ed together.

For more detailed information about these attributes refer to your operating system documentation.

ff_ftime and ff_fdate contain bit fields for referring to the current date and time. The structure of these fields was established by the operating system. Both are 16-bit structures divided into three fields.

ff_ftime:

Bits 0 to 4	The result of seconds divided by 2 (for example 10 here means 20 seconds)
Bits 5 to 10	Minutes
Bits 11 to 15	Hours

ff_fdate:

Bits 0-4	Day
Bits 5-8	Month
Bits 9-15	Years since 1980 (for example 9 here means 1989)

The structure ftime declared in io.h uses time and date bit fields similar in structure to ff_ftime and ff_fdate.

Return Value

findfirst returns 0 on successfully finding a file matching the search pathname.

When no more files can be found, or if there is an error in the file name:

- -1 is returned
- errno is set to

ENOENT	Path or file name not found

- _doserrno is set to one of the following values:

ENMFILE	No more files
ENOENT	Path or file name not found

Example

```
/* findfirst and findnext example */
#include <stdio.h>
#include <dir.h>
int main(void)
{
   struct ffblk ffblk;
   int done;
   printf("Directory listing of *.*\n");
   done = findfirst("*.*",&ffblk,0);
   while (!done)
   {
      printf("  %s\n", ffblk.ff_name);
      done = findnext(&ffblk);
   }
   return 0;
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
findfirst		+		
_wfindfirst		NT only		

See Also

findclose (see page 804)

findnext (see page 807)

3.1.4.8.5 findnext, _wfindnext

Header File

dir.h

Category

Directory Control Routines

Prototype

```
int findnext(struct ffblk *ffblk );
```

```
int _wfindnext(struct _wffblk *ffblk );
```

Description

Continues findfirst search.

findnext is used to fetch subsequent files that match the pathname given in findfirst. ffblk is the same block filled in by the findfirst call. This block contains necessary information for continuing the search. One file name for each call to findnext will be returned until no more files are found in the directory matching the pathname.

Return Value

findnext returns 0 on successfully finding a file matching the search pathname. When no more files can be found or if there is an error in the file name

-1 is returned

errno is set to

ENOENT	Path or file name not found

_doserrno is set to one of the following values:

ENMFILE	No more files
ENOENT	Path or file name not found

Portability

	POSIX	Win32	ANSI C	ANSI C++
findnext		+		
_wfindnext		NT only		

See Also

findfirst (see page 805)

3.1.4.8.6 fnmerge, _wfnmerge

Header File

dir.h

Category

Directory Control Routines

Prototype

```
void fnmerge(char *path, const char *drive, const char *dir, const char *name, const char *ext);
```

```
void _wfnmerge(wchar_t *path, const wchar_t *drive, const wchar_t *dir, const wchar_t *name, const wchar_t *ext );
```

Description

Builds a path from component parts.

fnmerge makes a path name from its components. The new path name is

`X:\DIR\SUBDIR\NAME.EXT`

where:

drive	=	X
dir	=	\\DIR\\SUBDIR\\
name	=	NAME
ext	=	.EXT

If drive is empty or NULL, no drive is inserted in the path name. If it is missing a trailing colon (:), a colon is inserted in the path name.

If dir is empty or NULL, no directory is inserted in the path name. If it is missing a trailing slash (\ or /), a backslash is inserted in the path name.

If name is empty or NULL, no file name is inserted in the path name.

If ext is empty or NULL, no extension is inserted in the path name. If it is missing a leading period (.), a period is inserted in the path name.

fnmerge assumes there is enough space in path for the constructed path name. The maximum constructed length is MAXPATH. MAXPATH is defined in dir.h.

fnmerge and fnsplit are invertible; if you split a given path with fnsplit then merge the resultant components with fnmerge you end up with path.

Return Value

None.

Example

```
#include <string.h>
#include <stdio.h>
#include <dir.h>
int main(void)
{
   char s[MAXPATH];
   char drive[MAXDRIVE];
   char dir[MAXDIR];
   char file[MAXFILE];
   char ext[MAXEXT];
   getcwd(s,MAXPATH);              /* get the current working directory */
   strcat(s,"\\");                 /* append on a trailing character */
   fnsplit(s,drive,dir,file,ext);  /* split the string to separate elems */
   strcpy(file,"DATA");
   strcpy(ext,".TXT");
   fnmerge(s,drive,dir,file,ext);   /* merge everything into one string */
   puts(s);                         /* display resulting string */
   return 0;
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
fnmerge		+		
_wfnmerge		NT only		

3.1.4.8.7 fnsplit, _wfnsplit

Header File

dir.h

Category

Directory Control Routines

Prototype

```
int fnsplit(const char *path, char *drive, char *dir, char *name, char *ext);
```

```
int _wfnsplit(const wchar_t *path, wchar_t *drive, wchar_t *dir, wchar_t *name, wchar_t *ext );
```

Description

Splits a full path name into its components.

fnsplit takes a file's full path name (path) as a string in the form X:\DIR\SUBDIR\NAME.EXT and splits path into its four components. It then stores those components in the strings pointed to by drive, dir, name, and ext. All five components must be passed but any of them can be a null which means the corresponding component will be parsed but not stored. If any path component is null, that component corresponds to a non-NULL, empty string.

The maximum sizes for these strings are given by the constants MAXDRIVE, MAXDIR, MAXPATH, MAXFILE, and MAXEXT (defined in dir.h) and each size includes space for the null-terminator.

fnsplit assumes that there is enough space to store each non-null component.

- When fnsplit splits path it treats the punctuation as follows:
- drive includes the colon (C:, A:, and so on)
- dir includes the leading and trailing backslashes (\BC\include\, \source\ ,and so on)
- name includes the file name
- ext includes the dot preceding the extension (.C, .EXE, and so on).

fnmerge and fnsplit are invertible; if you split a given path with fnsplit then merge the resultant components with fnmerge you end up with path.

Return Value

fnsplit returns an integer (composed of five flags defined in dir.h) indicating which of the full path name components were present in path. These flags and the components they represent are

EXTENSION	An extension
FILENAME	A file name
DIRECTORY	A directory (and possibly subdirectories)
DRIVE	A drive specification (see dir.h)
WILDCARDS	Wildcards (* or ?)

Example

```
#include <stdlib.h>
#include <stdio.h>
#include <dir.h>
int main(void)
{
    char *s;
    char drive[MAXDRIVE];
```

```
    char dir[MAXDIR];
    char file[MAXFILE];
    char ext[MAXEXT];
    int flags;
    s=getenv("COMSPEC"); /* get the comspec environment parameter */
    flags=fnsplit(s,drive,dir,file,ext);
    printf("Command processor info:\n");
    if(flags & DRIVE)
       printf("\tdrive: %s\n",drive);
    if(flags & DIRECTORY)
       printf("\tdirectory: %s\n",dir);
    if(flags & FILENAME)
       printf("\tfile: %s\n",file);
    if(flags & EXTENSION)
       printf("\textension: %s\n",ext);
    return 0;
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
fnsplit		+		
_wfnsplit		NT only		

3.1.4.8.8 Bit Definitions for fnsplit

Header File

dir.h

Description

Bit definitions returned from fnsplit to identify which pieces of a file name were found during the split.

Flag	Component
DIRECTORY	Path includes a directory (and possibly subdirectories)
DRIVE	Path includes a drive specification (see DIR.H)
EXTENSION	Path includes an extension
FILENAME	Path includes a file name
WILDCARDS	Path contains wildcards (* or ?)

3.1.4.8.9 getcurdir, _wgetcurdir

Header File

dir.h

Category

Directory Control Routines

Prototype

```
int getcurdir(int drive, char *directory);
```

```
int _wgetcurdir(int drive, wchar_t *directory );
```

Description

Gets current directory for specified drive.

getcurdir gets the name of the current working directory for the drive indicated by drive. drive specifies a drive number (0 for default, 1 for A, and so on). directory points to an area of memory of length MAXDIR where the null-terminated directory name will be placed. The name does not contain the drive specification and does not begin with a backslash.

Return Value

getcurdir returns 0 on success or -1 in the event of error.

Example

```
#include <dir.h>
#include <stdio.h>
#include <string.h>
char *current_directory(char *path)
{
  strcpy(path, "X:\\");      /* fill string with form of response: X:\ */
  path[0] = 'A' + getdisk();    /* replace X with current drive letter */
  getcurdir(0, path+3);  /* fill rest of string with current directory */
  return(path);
}
int main(void)
{
  char curdir[MAXPATH];
  current_directory(curdir);
  printf("The current directory is %s\n", curdir);
  return 0;
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
getcurdir		+		
_wgetcurdir		NT only		

3.1.4.8.10 getcwd, _wgetcwd

Header File

dir.h

Category

Directory Control Routines

Prototype

```
char *getcwd(char *buf, int buflen);
```

```
wchar_t *_wgetcwd(wchar_t *buf, int buflen);
```

Description

Gets current working directory.

getcwd gets the full path name (including the drive) of the current working directory, up to buflen bytes long and stores it in buf. If the full path name length (including the null terminator) is longer than buflen bytes, an error occurs.

If buf is NULL, a buffer buflen bytes long is allocated for you with malloc. You can later free the allocated buffer by passing the return value of getcwd to the function free.

Return Value

- getcwd returns the following values:
- If buf is not NULL on input, getcwd returns buf on success, NULL on error.
- If buf is NULL on input, getcwd returns a pointer to the allocated buffer.

In the event of an error return, the global variable errno is set to one of the following values:

ENODEV	No such device
ENOMEM	Not enough memory to allocate a buffer (buf is NULL)
ERANGE	Directory name longer than buflen (buf is not NULL)

Example

```
#include <stdio.h>
#include <dir.h>
int main(void)
{
   char buffer[MAXPATH];
   getcwd(buffer, MAXPATH);
   printf("The current directory is: %s\n", buffer);
   return 0;
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
getcwd	+	+		
_wgetcwd		NT only		

3.1.4.8.11 getdisk, setdisk

Header File

dir.h

Category

Directory Control Routines

Prototype

```
int getdisk(void);
```

```
int setdisk(int drive);
```

Description

Gets or sets the current drive number.

getdisk gets the current drive number. It returns an integer: 0 for A, 1 for B, 2 for C, and so on.

setdisk sets the current drive to the one associated with drive: 0 for A, 1 for B, 2 for C, and so on.

The setdisk function changes the current drive of the parent process.

Return Value

getdisk returns the current drive number. setdisk returns the total number of drives available.

Example

```
#include <stdio.h>
#include <dir.h>
int main(void)
{
  int disk, maxdrives = setdisk(2);
  disk = getdisk() + 'A';
  printf("\nThe number of logical drives is:%d\n", maxdrives);
  printf("The current drive is: %c\n", disk);
  return 0;
 }
```

3.1.4.8.12 mkdir, _wmkdir

Header File

dir.h

Category

Directory Control Routines

Prototype

```
int mkdir(const char *path);
```

```
int _wmkdir(const wchar_t *path);
```

Description

Creates a directory.

mkdir is available on UNIX, though it then takes an additional parameter.

mkdir creates a new directory from the given path name path.

Return Value

mkdir returns the value 0 if the new directory was created.

A return value of -1 indicates an error, and the global variable errno is set to one of the following values:

EACCES	Permission denied
ENOENT	No such file or directory

Example

```
#include <stdio.h>
#include <process.h>
#include <dir.h>
#define DIRNAME "testdir.$$$"
int main(void)
{
    int stat;
    stat = mkdir(DIRNAME);
    if (!stat)
           printf("Directory created\n");
    else
    {
       printf("Unable to create directory\n");
       exit(1);
    }
    getchar();
    system("dir/p");
    getchar();
    stat = rmdir(DIRNAME);
```

```
    if (!stat)
          printf("\nDirectory deleted\n");
    else
    {
          perror("\nUnable to delete directory\n");
       exit(1);
    }
    return 0;
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
mkdir	+	+		
_wmkdir		NT only		

3.1.4.8.13 _mktemp, _wmktemp

Header File

dir.h

Category

Directory Control Routines

Prototype

```
char *_mktemp(char *template);
```

```
wchar_t *_wmktemp(wchar_t *template);
```

Description

Makes a unique file name.

_mktemp replaces the string pointed to by template with a unique file name and returns template.

template should be a null-terminated string with six trailing Xs. These Xs are replaced with a unique collection of letters plus a period, so that there are two letters, a period, and three suffix letters in the new file name.

Starting with AA.AAA, the new file name is assigned by looking up the name on the disk and avoiding pre-existing names of the same format.

Return Value

If a unique name can be created and template is well formed, _mktemp returns the address of the template string. Otherwise, it returns null.

Example

```
#include <dir.h>
#include <stdio.h>
int main(void)
{
    /* fname defines the template for the
      temporary file.  */
    char *fname = "TXXXXXX", *ptr;
    ptr = mktemp(fname);
    printf("%s\n",ptr);
    return 0;
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
mktemp	+	+		
_wmktemp		+		

3.1.4.8.14 _rmdir, _wrmdir

Header File

dir.h

Category

Directory Control Routines

Prototype

```
int _rmdir(const char *path);
```

```
int _wrmdir(const wchar_t *path);
```

Description

Removes a directory.

_rmdir deletes the directory whose path is given by path. The directory named by path

- must be empty
- must not be the current working directory
- must not be the root directory

Return Value

_rmdir returns 0 if the directory is successfully deleted. A return value of -1 indicates an error, and the global variable errno is set to one of the following values:

EACCES	Permission denied
ENOENT	Path or file function not found

Example

```
#include <stdio.h>
#include <process.h>
#include <dir.h>
#define DIRNAME "testdir.$$$"
int main(void)
{
    int stat;
    stat = mkdir(DIRNAME);
    if (!stat)
            printf("Directory created\n");
    else
    {
       printf("Unable to create directory\n");
       exit(1);
    }
    getchar();
    system("dir/p");
    getchar();
    stat = rmdir(DIRNAME);
```

```
    if (!stat)
          printf("\nDirectory deleted\n");
    else
    {
          perror("\nUnable to delete directory\n");
       exit(1);
    }
    return 0;
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
_rmdir	+	+		
_wrmdir		NT only		

3.1.4.8.15 searchpath, wsearchpath

Header File

dir.h

Category

Miscellaneous Routines

Prototype

```
char *searchpath(const char *file);
```

```
wchar_t *wsearchpath( const wchar_t *file );
```

Description

Searches the operating system path for a file.

searchpath attempts to locate file, searching along the operating system path, which is the PATH=... string in the environment. A pointer to the complete path-name string is returned as the function value.

searchpath searches for the file in the current directory of the current drive first. If the file is not found there, the PATH environment variable is fetched, and each directory in the path is searched in turn until the file is found, or the path is exhausted.

When the file is located, a string is returned containing the full path name. This string can be used in a call to access the file (for example, with fopen or exec...).

The string returned is located in a static buffer and is overwritten on each subsequent call to searchpath.

Return Value

searchpath returns a pointer to a file name string if the file is successfully located; otherwise, searchpath returns null.

Example

```
#include <stdio.h>
#include <dir.h>
int main(void)
{
    char *p;
    /* Looks for ILINK32 and returns a pointer
       to the path  */
    p = searchpath("ILINK32.EXE");
    printf("Search for ILINK32.EXE : %s\n", p);
    /* Looks for nonexistent file  */
```

```
    p = searchpath("NOTEXIST.FIL");
    printf("Search for NOTEXIST.FIL : %s\n", p);
    return 0;
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
searchpath		+		
wsearchpath		NT only		

3.1.4.9 dos.h

The following functions, macros, and classes are provided in `dos.h`:

Topics

Name	Description
FA_xxxx #defines (see page 822)	**Header File** dos.h **Description** File attributes
NFDS #define (see page 822)	**Header File** dos.h **Description** Maximum number of file descriptors.
_getdrive (see page 822)	**Header File** dos.h **Category** Directory Control Routines **Prototype** `int _getdrive(void);` **Description** Gets the current drive. _getdrive gets the the current drive number. It returns an integer: 0 for A, 1 for B, 2 for C, and so on. **Return Value** _getdrive returns the current drive number on success or -1 in the event of error. **Example**
_osmajor (see page 823)	**Header File** dos.h **Syntax** `extern unsigned char _osmajor;` **Description** The major version number of the operating system is available individually through _osmajor. For example, if you are running DOS version 3.2, _osmajor will be 3. This variable can be useful when you want to write modules that will run on DOS versions 2.x and 3.x. Some library routines behave differently depending on the DOS version number, while others only work under DOS 3.x and higher. For example, refer to creatnew and _rtl_open.

_osminor (see page 823)	**Header File** dos.h **Syntax** `extern unsigned char _osminor;` **Description** The minor version number of the operating system is available individually through _osminor. For example, if you are running DOS version 3.2, _osminor will be 20. This variables can be useful when you want to write modules that will run on DOS versions 2.x and 3.x. Some library routines behave differently depending on the DOS version number, while others only work under DOS 3.x and higher. For example, refer to creatnew and _rtl_open.
_osversion (see page 823)	**Header File** dos.h **Syntax** `extern unsigned _osversion;` **Description** _osversion contains the operating system version number, with the major version number in the low byte and the minor version number in the high byte. (For DOS version x.y, the x is the major version number, and y is the minor version number.) _osversion is functionally identical to _version.
_sleep (see page 824)	**Header File** dos.h **Category** Process Control Routines **Prototype** `void _sleep(unsigned seconds);` **Description** Suspends execution for an interval (seconds). With a call to _sleep, the current program is suspended from execution for the number of seconds specified by the argument seconds. The interval is accurate only to the nearest hundredth of a second or to the accuracy of the operating system clock, whichever is less accurate. **Return Value** None. **Example**
_version (see page 824)	**Header File** dos.h **Syntax** `extern unsigned _version;` **Description** _version contains the operating system version number, with the major version number in the low byte and the minor version number in the high byte. (For DOS version x.y, the x is the major version number, and y is the minor version number.)

disable, _disable, enable, _enable (see page 825)	**Header File**
	dos.h
	Category
	Miscellaneous Routines
	Prototype
	`void disable(void);`
	`void _disable(void);`
	`void enable(void);`
	`void _enable(void);`
	Description
	Disables and enables interrupts.
	These macros are designed to provide a programmer with flexible hardware interrupt control.
	disable and _disable macros disable interrupts. Only the NMI (non-maskable interrupt) is allowed from any external device.
	enable and _enable macros enable interrupts, allowing any device interrupts to occur.
	Return Value
	None.
	Portability

dostounix (see page 825)	**Header File** dos.h **Category** Time and Date Routines **Prototype** `long dostounix(struct date *d, struct time *t);` **Description** **Converts date and time to UNIX time format.** **dostounix converts a date and time as returned from getdate and gettime into UNIX time format. d points to a date structure, and t points to a time structure containing valid date and time information.** **The date and time must not be earlier than or equal to Jan 1 1980 00:00:00.** **Return Value** Returns UNIX version of current date and time parameters: number of seconds since 00:00:00 on January 1, 1970 (GMT). **Example**
geninterrupt (see page 826)	**Header File** **Category** **Prototype** `void geninterrupt(int intr_num);` **Description** **Return Value** **Portability**

getdate, setdate (see page 826)	**Header File**
	dos.h
	Category
	Time and Date Routines
	Prototype
	`void getdate(struct date *datep);`
	`void setdate(struct date *datep);`
	Description
	Gets and sets system date.
	getdate fills in the date structure (pointed to by datep) with the system's current date.
	setdate sets the system date (month, day, and year) to that in the date structure pointed to by datep. Note that a request to set a date might fail if you do not have the privileges required by the operating system.
	The date structure is defined as follows:
	`struct date{`
	`int da_year; /* current year */`
	`char da_day; /* day of the...  more (see page 826)`

getdfree (see page 827)	**Header File**
	dos.h
	Category
	Directory Control Routines, Miscellaneous Routines
	Prototype
	void getdfree(unsigned char drive, struct dfree *dtable);
	Description
	Gets disk free space.
	getdfree accepts a drive specifier in drive (0 for default, 1 for A, and so on) and fills the dfree structure pointed to by dtable with disk attributes.
	The dfree structure is defined as follows:
	`struct dfree {`
	`unsigned df_avail; /* available clusters */`
	`unsigned df_total; /* total clusters */`
	`unsigned df_bsec; /* bytes per sector */`
	`unsigned df_sclus; /* sectors per cluster */`
	`};`
	Return Value
	getdfree returns no value. In the event of an error, df_sclus... more (see page 827)

gettime, settime (see page 828)	**Header File**
	dos.h
	Category
	Time and Date Routines
	Prototype
	`void gettime(struct time *timep);`
	`void settime(struct time *timep);`
	Description
	Gets and sets the system time.
	gettime fills in the time structure pointed to by timep with the system's current time.
	• settime sets the system time to the values in the time structure pointed to by timep.
	The time structure is defined as follows:
	`struct time {`
	`unsigned char ti_min; /* minutes */`
	`unsigned char ti_hour; /* hours */`
	`unsigned char ti_hund; /* hundredths of seconds */`
	`unsigned char ti_sec; /* seconds */`
	`};`
	Return Value
	None.
	Example

unixtodos (see page 829)	**Header File** dos.h **Category** Time and Date Routines **Prototype** `void unixtodos(long time, struct date *d, struct time *t);` **Description** Converts date and time from UNIX to DOS format. unixtodos converts the UNIX-format time given in time to DOS format and fills in the date and time structures pointed to by d and t. time must not represent a calendar time earlier than Jan. 1, 1980 00:00:00. **Return Value** None. **Example**

_unlink, _wunlink (see page 830)	**Header File**
	dos.h
	Category
	Input/output Routines
	Prototype
	`int _unlink(const char *filename);`
	`int _wunlink(const wchar_t *filename);`
	Description
	Deletes a file.
	_unlink deletes a file specified by filename. Any drive, path, and file name can be used as a filename. Wildcards are not allowed.
	Read-only files cannot be deleted by this call. To remove read-only files, first use chmod or _rtl_chmod to change the read-only attribute.
	Note: If the file is open, it must be closed before unlinking it.
	_wunlink is the Unicode version of _wunlink. The Unicode version accepts a filename that is a wchar_t character string. Otherwise, the functions perform... more (see page 830)

3.1.4.9.1 FA_xxxx #defines

Header File

dos.h

Description

File attributes

Constant	Description
FA_RDONLY	Read-only attribute
FA_HIDDEN	Hidden file
FA_SYSTEM	System file
FA_LABEL	Volume label
FA_DIREC	Directory
FA_ARCH	Archive

3.1.4.9.2 NFDS #define

Header File

dos.h

Description

Maximum number of file descriptors.

3.1.4.9.3 _getdrive

Header File

dos.h

Category

Directory Control Routines

Prototype

```
int _getdrive(void);
```

Description

Gets the current drive.

_getdrive gets the the current drive number. It returns an integer: 0 for A, 1 for B, 2 for C, and so on.

Return Value

_getdrive returns the current drive number on success or -1 in the event of error.

Example

```
#include <stdio.h>
#include <direct.h>
int main(void)
```

```
{
  int disk;
  disk = _getdrive() + 'A' - 1;
  printf("The current drive is: %c\n", disk);
  return 0;
}
```

3.1.4.9.4 _osmajor

Header File

dos.h

Syntax

```
extern unsigned char _osmajor;
```

Description

The major version number of the operating system is available individually through _osmajor. For example, if you are running DOS version 3.2, _osmajor will be 3.

This variable can be useful when you want to write modules that will run on DOS versions 2.x and 3.x. Some library routines behave differently depending on the DOS version number, while others only work under DOS 3.x and higher. For example, refer to creatnew and _rtl_open.

3.1.4.9.5 _osminor

Header File

dos.h

Syntax

```
extern unsigned char _osminor;
```

Description

The minor version number of the operating system is available individually through _osminor. For example, if you are running DOS version 3.2, _osminor will be 20.

This variables can be useful when you want to write modules that will run on DOS versions 2.x and 3.x. Some library routines behave differently depending on the DOS version number, while others only work under DOS 3.x and higher. For example, refer to creatnew and _rtl_open.

3.1.4.9.6 _osversion

Header File

dos.h

Syntax

```
extern unsigned _osversion;
```

Description

_osversion contains the operating system version number, with the major version number in the low byte and the minor version number in the high byte. (For DOS version x.y, the x is the major version number, and y is the minor version number.)

_osversion is functionally identical to _version.

3.1.4.9.7 _sleep

Header File

dos.h

Category

Process Control Routines

Prototype

```
void _sleep(unsigned seconds);
```

Description

Suspends execution for an interval (seconds).

With a call to _sleep, the current program is suspended from execution for the number of seconds specified by the argument seconds. The interval is accurate only to the nearest hundredth of a second or to the accuracy of the operating system clock, whichever is less accurate.

Return Value

None.

Example

```
#include <dos.h>
#include <stdio.h>
int main(void)
{
   int i;
   for (i=1; i<5; i++)
   {
      printf("Sleeping for %d seconds\n", i);
      _sleep(i);
   }
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.9.8 _version

Header File

dos.h

Syntax

```
extern unsigned _version;
```

Description

_version contains the operating system version number, with the major version number in the low byte and the minor version number in the high byte. (For DOS version x.y, the x is the major version number, and y is the minor version number.)

3.1.4.9.9 disable, _disable, enable, _enable

Header File

dos.h

Category

Miscellaneous Routines

Prototype

```
void disable(void);
void _disable(void);
void enable(void);
void _enable(void);
```

Description

Disables and enables interrupts.

These macros are designed to provide a programmer with flexible hardware interrupt control.

disable and _disable macros disable interrupts. Only the NMI (non-maskable interrupt) is allowed from any external device.

enable and _enable macros enable interrupts, allowing any device interrupts to occur.

Return Value

None.

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.9.10 dostounix

Header File

dos.h

Category

Time and Date Routines

Prototype

```
long dostounix(struct date *d, struct time *t);
```

Description

Converts date and time to UNIX time format.

dostounix converts a date and time as returned from getdate and gettime into UNIX time format. d points to a date structure, and t points to a time structure containing valid date and time information.

The date and time must not be earlier than or equal to Jan 1 1980 00:00:00.

Return Value

Returns UNIX version of current date and time parameters: number of seconds since 00:00:00 on January 1, 1970 (GMT).

Example

```
#include <time.h>
#include <stddef.h>
#include <dos.h>
#include <stdio.h>
int main(void)
{
  time_t t;
  struct time d_time;
  struct date d_date;
  struct tm *local;
  getdate(&d_date);
  gettime(&d_time);
  t = dostounix(&d_date, &d_time);
  local = localtime(&t);
  printf("Time and Date: %s\n", asctime(local));
  return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.9.11 geninterrupt

Header File

Category

Prototype

```
void geninterrupt(int intr_num);
```

Description

Return Value

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.9.12 getdate, setdate

Header File

dos.h

Category

Time and Date Routines

Prototype

```
void getdate(struct date *datep);
```

```
void setdate(struct date *datep);
```

Description

Gets and sets system date.

getdate fills in the date structure (pointed to by datep) with the system's current date.

setdate sets the system date (month, day, and year) to that in the date structure pointed to by datep. Note that a request to set a date might fail if you do not have the privileges required by the operating system.

The date structure is defined as follows:

```
struct date{
int da_year; /* current year */
char da_day; /* day of the month */
char da_mon; /* month (1 = Jan) */
};
```

Return Value

getdate and setdate do not return a value.

Example

```
#include <dos.h>
#include <stdio.h>
int main(void)
{
   struct date d;
   getdate(&d);
   printf("The current year is: %d\n", d.da_year);
   printf("The current day is: %d\n", d.da_day);
   printf("The current month is: %d\n", d.da_mon);
   return 0;
}
```

3.1.4.9.13 getdfree

Header File

dos.h

Category

Directory Control Routines, Miscellaneous Routines

Prototype

```
void getdfree(unsigned char drive, struct dfree *dtable);
```

Description

Gets disk free space.

getdfree accepts a drive specifier in drive (0 for default, 1 for A, and so on) and fills the dfree structure pointed to by dtable with disk attributes.

The dfree structure is defined as follows:

```
struct dfree {
unsigned df_avail; /* available clusters */
unsigned df_total; /* total clusters */
```

```
unsigned df_bsec; /* bytes per sector */
unsigned df_sclus; /* sectors per cluster */
};
```

Return Value

getdfree returns no value. In the event of an error, df_sclus in the dfree structure is set to (**unsigned**) -1.

Example

```
#include <stdio.h>
#include <dos.h>
#include <process.h>
int main(void)
{
  struct dfree free;
  long avail;
  getdfree(0, &free);
  if ( free.df_sclus == -1)
  {
    printf("Error in getdfree() call\n");
    exit(1);
  }
  avail = (long) free.df_avail
        * (long) free.df_bsec
        * (long) free.df_sclus;
  printf("The current drive has %ld bytes available\n", avail);
  return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.9.14 gettime, settime

Header File

dos.h

Category

Time and Date Routines

Prototype

```
void gettime(struct time *timep);
void settime(struct time *timep);
```

Description

Gets and sets the system time.

gettime fills in the time structure pointed to by timep with the system's current time.

- settime sets the system time to the values in the time structure pointed to by timep.

The time structure is defined as follows:

```
struct time {
unsigned char ti_min; /* minutes */
```

```
unsigned char ti_hour; /* hours */
unsigned char ti_hund; /* hundredths of seconds */
unsigned char ti_sec; /* seconds */
};
```

Return Value

None.

Example

```
#include   <stdio.h>
#include   <dos.h>
int main(void)
{
   struct  time t;
   gettime(&t);
   printf("The current time is: %2d:%02d:%02d.%02d\n",
          t.ti_hour, t.ti_min, t.ti_sec, t.ti_hund);
   return 0;
}
```

3.1.4.9.15 unixtodos

Header File

dos.h

Category

Time and Date Routines

Prototype

```
void unixtodos(long time, struct date *d, struct time *t);
```

Description

Converts date and time from UNIX to DOS format.

unixtodos converts the UNIX-format time given in time to DOS format and fills in the date and time structures pointed to by d and t.

time must not represent a calendar time earlier than Jan. 1, 1980 00:00:00.

Return Value

None.

Example

```
#include <stdio.h>
#include <dos.h>
char *month[] = {"---", "Jan", "Feb", "Mar", "Apr", "May", "Jun",
                 "Jul", "Aug", "Sep", "Oct", "Nov", "Dec"};
#define SECONDS_PER_DAY 86400L  /* the number of seconds in one day */
struct date dt;
struct time tm;
int main(void)
{
   unsigned long val;
/* get today's date and time */
   getdate(&dt);
   gettime(&tm);
   printf("today is %d %s %d\n", dt.da_day, month[dt.da_mon], dt.da_year);
/*convert date and time to unix format (num of seconds since Jan 1, 1970*/
```

```
   val = dostounix(&dt, &tm);
/* subtract 42 days worth of seconds */
   val -= (SECONDS_PER_DAY * 42);
/* convert back to dos time and date */
   unixtodos(val, &dt, &tm);
   printf("42 days ago it was %d %s %d\n",
          dt.da_day, month[dt.da_mon], dt.da_year);
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.9.16 _unlink, _wunlink

Header File

dos.h

Category

Input/output Routines

Prototype

```
int _unlink(const char *filename);
```

```
int _wunlink(const wchar_t *filename);
```

Description

Deletes a file.

_unlink deletes a file specified by filename. Any drive, path, and file name can be used as a filename. Wildcards are not allowed.

Read-only files cannot be deleted by this call. To remove read-only files, first use chmod or _rtl_chmod to change the read-only attribute.

Note: If the file is open, it must be closed before unlinking it.

_wunlink is the Unicode version of _wunlink. The Unicode version accepts a filename that is a wchar_t character string. Otherwise, the functions perform identically.

Return Value

On success, _unlink returns 0.

On error, it returns -1 and sets the global variable errno to one of the following values:

EACCES	Permission denied
ENOENT	Path or file name not found

Example

```
#include <stdio.h>
#include <io.h>
int main(void)
{
   FILE *fp = fopen("junk.jnk","w");
   int status;
   fprintf(fp,"junk");
```

```
    status = access("junk.jnk",0);
    if (status == 0)
       printf("File exists\n");
    else
       printf("File doesn't exist\n");
    fclose(fp);
    unlink("junk.jnk");
    status = access("junk.jnk",0);
    if (status == 0)
       printf("File exists\n");
    else
       printf("File doesn't exist\n");
    return 0;
}
```

3.1.4.10 errno.h

The following functions, macros, and classes are provided in `errno.h`:

Topics

Name	Description
EDOM, ERANGE, #defines (see page 832)	**Header File** errno.h, math.h **Description** These are the mnemonics and meanings for the error numbers found in math.h and errno.
_doserrno (see page 833)	**Header File** errno.h **Syntax** `extern int _doserrno;` **Description** _doserrno is a variable that maps many operating system error codes to errno; however, perror does not use _doserrno directly. When an operating system call results in an error, _doserrno is set to the actual operating system error code. errno is a parallel error variable inherited from UNIX. The following list gives mnemonics for the actual DOS error codes to which _doserrno can be set. (This value of _doserrno may or may not be mapped (through errno) to an equivalent error message string in _sys_errlist.
errno (C Runtime Library Reference) (see page 833)	**Header File** errno.h **Syntax** `extern int errno;` **Description** errno is used by perror to print error messages when certain library routines fail to accomplish their appointed tasks. When an error in a math or system call occurs, errno is set to indicate the type of error. Sometimes errno and _doserrno are equivalent. At other times, errno does not contain the actual operating system error code, which is contained in _doserrno. Still other errors might occur that set only errno, not _doserrno.

Error Numbers in errno (see page 834)	**Header File** errno.h **Description** These are the mnemonics and meanings for the error numbers found in errno. Each value listed can be used to index into the sys_errlist array for displaying messages. Also, perror will display messages.

perror,_wperror (see page 835)	**Header File**
	errno.h, stdio.h
	Category
	Diagnostic Routines, Input/output Routines
	Prototype
	`void perror(const char *s);`
	`void _wperror(const wchar_t *s);`
	Description
	Prints a system error message.
	perror prints to the stderr stream (normally the console) the system error message for the last library routine that set the global variable errno.
	It prints the argument s followed by a colon (:) and the message corresponding to the current value of the global variable errno and finally a new line. The convention is to pass the file name of the program as the argument string.
	The array of error message strings is accessed through... more (see page 835)

_sys_errlist (see page 837)	**Header File**
	errno.h
	Syntax
	`extern char * _sys_errlist[ ];`
	Description
	_sys_errlist is used by perror to print error messages when certain library routines fail to accomplish their appointed tasks.
	To provide more control over message formatting, the array of message strings is provided in _sys_errlist. You can use errno as an index into the array to find the string corresponding to the error number. The string does not include any newline character.
	Example
	`printf("%s\n", _sys_errlist[ENOPATH]);`
	This code statement that uses the Mnemonic ENOPATH will output the string "Path not found".
	The following table gives mnemonics and their meanings for the... more (see page 837)

_sys_nerr (see page 838)	**Header File** errno.h **Syntax** `extern int _sys_nerr;` **Description** _sys_nerr is used by perror to print error messages when certain library routines fail to accomplish their appointed tasks. This variable is defined as the number of error message strings in _sys_errlist.

3.1.4.10.1 EDOM, ERANGE, #defines

Header File

errno.h, math.h

Description

These are the mnemonics and meanings for the error numbers found in math.h and errno.

Name	Meaning
EDOM	Error code for math domain error
ERANGE	Error code for result out of range

3.1.4.10.2 _doserrno

Header File

errno.h

Syntax

```
extern int _doserrno;
```

Description

_doserrno is a variable that maps many operating system error codes to errno; however, perror does not use _doserrno directly.

When an operating system call results in an error, _doserrno is set to the actual operating system error code. errno is a parallel error variable inherited from UNIX.

The following list gives mnemonics for the actual DOS error codes to which _doserrno can be set. (This value of _doserrno may or may not be mapped (through errno) to an equivalent error message string in _sys_errlist.

E2BIG	Bad environ
EACCES	Access denied
EACCES	Bad access
EACCES	Is current dir
EBADF	Bad handle
EFAULT	Reserved
EINVAL	Bad data
EINVAL	Bad function
EMFILE	Too many open
ENOENT	No such file or directory
ENOEXEC	Bad format
ENOMEM	Mcb destroyed
ENOMEM	Out of memory
ENOMEM	Bad block
EXDEV	Bad drive
EXDEV	Not same device

3.1.4.10.3 errno (C Runtime Library Reference)

Header File

errno.h

Syntax

```
extern int errno;
```

Description

errno is used by perror to print error messages when certain library routines fail to accomplish their appointed tasks.

When an error in a math or system call occurs, errno is set to indicate the type of error. Sometimes errno and _doserrno are

equivalent. At other times, errno does not contain the actual operating system error code, which is contained in _doserrno. Still other errors might occur that set only errno, not _doserrno.

3.1.4.10.4 Error Numbers in errno

Header File

errno.h

Description

These are the mnemonics and meanings for the error numbers found in errno.

Each value listed can be used to index into the sys_errlist array for displaying messages.

Also, perror will display messages.

Mnemonic	Meaning
EZERO	Error 0
EINVFNC	Invalid function number
ENOFILE	File not found
ENOPATH	Path not found
ECONTR	Memory blocks destroyed
EINVMEM	Invalid memory block address
EINVENV	Invalid environment
EINVFMT	Invalid format
EINVACC	Invalid access code
EINVDAT	Invalid data
EINVDRV	Invalid drive specified
ECURDIR	Attempt to remove CurDir
ENOTSAM	Not same device
ENMFILE	No more files
ENOENT	No such file or directory
EMFILE	Too many open files
EACCES	Permission denied
EBADF	Bad file number
ENOMEM	Not enough memory
EFAULT	Unknown error
ENODEV	No such device
EINVAL	Invalid argument
E2BIG	Arg list too long
ENOEXEC	Exec format error
EXDEV	Cross-device link
ENFILE	Too many open files
ECHILD	No child process

ENOTTY	Terminal control function attempted on a file that is not a terminal. (POSIX – Not used in Win32 applications.)
ETXTBSY	Not used in Win32 applications
EFBIG	An attempt was made to write to a file, beyond the maximum file size. (POSIX – Not used in Win32 applications.)
ESOSPC	No space left on device
ESPIPE	Illegal seek
EROFS	Read-only file system
EMLINK	The number of links exceeds LINK_MAX. (POSIX – Not used in Win32 applications.)
EPIPE	Broken pipe
EDOM	Math argument
ERANGE	Result too large
EEXIST	File already exists
EDEADLOCK	Locking violation
EPERM	Operation not permitted
ESRCH	No such process id. (POSIX – Not used in Win32 applications.)
EINTR	Interrupted function call
EIO	Input/output error
ENXIO	No such device or address
EAGAIN	Resource temporarily unavailable
ENOTBLK	Not used in Win32 applications
EBUSY	Resource busy
ENOTDIR	A pathname component is not a directory. (POSIX – Not used in Win32 applications.)
EISDIR	An attempt was made to open a directory for writing, or to rename a file with the same name as an existing directory. (POSIX – Not used in Win32 applications.)
EUCLEAN	Not used in Win32 console applications

3.1.4.10.5 perror,_wperror

Header File

errno.h, stdio.h

Category

Diagnostic Routines, Input/output Routines

Prototype

```
void perror(const char *s);
void _wperror(const wchar_t *s);
```

Description

Prints a system error message.

perror prints to the stderr stream (normally the console) the system error message for the last library routine that set the global

variable errno.

It prints the argument s followed by a colon (:) and the message corresponding to the current value of the global variable errno and finally a new line. The convention is to pass the file name of the program as the argument string.

The array of error message strings is accessed through the global variable _sys_errlist. The global variable errno can be used as an index into the array to find the string corresponding to the error number. None of the strings include a newline character.

The global variable _sys_nerr contains the number of entries in the array.

The following messages are generated by perror:

Note: For Win32 GUI applications, stderr must be redirected.

Arg list too big

Attempted to remove current directory

Bad address

Bad file number

Block device required

Broken pipe

Cross-device link

Error 0

Exec format error

Executable file in use

File already exists

File too large

Illegal seek

Inappropriate I/O control operation

Input/output error

Interrupted function call

Invalid access code

Invalid argument Resource busy

Invalid dataResource temporarily unavailable

Invalid environment

Invalid format

Invalid function number

Invalid memory block address

Is a directory

Math argument

Memory arena trashed

Name too long

No child processes

No more files

No space left on device

No such device

No such device or address

No such file or directory

No such process

Not a directory

Not enough memory

Not same device

Operation not permitted

Path not found

Permission denied

Possible deadlock

Read-only file system

Resource busy

Resource temporarily unavailable

Result too large

Too many links

Too many open files

Example

```
#include <stdio.h>
int main(void)
{
    FILE *fp;
    fp = fopen("perror.dat", "r");
    if (!fp)
       perror("Unable to open file for reading");
    return 0;
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
perror	+	+	+	+
_wperror		+		

3.1.4.10.6 _sys_errlist

Header File

errno.h

Syntax

```
extern char * _sys_errlist[ ];
```

Description

_sys_errlist is used by perror to print error messages when certain library routines fail to accomplish their appointed tasks.

To provide more control over message formatting, the array of message strings is provided in _sys_errlist. You can use errno as an index into the array to find the string corresponding to the error number. The string does not include any newline character.

Example

```
printf("%s\n", _sys_errlist[ENOPATH]);
```

This code statement that uses the Mnemonic ENOPATH will output the string "Path not found".

The following table gives mnemonics and their meanings for the values stored in _sys_errlist. The list is alphabetically ordered for ease your reading convenience. For the numerical ordering, see the header file errno.h.

3.1.4.10.7 _sys_nerr

Header File

errno.h

Syntax

```
extern int _sys_nerr;
```

Description

_sys_nerr is used by perror to print error messages when certain library routines fail to accomplish their appointed tasks.

This variable is defined as the number of error message strings in _sys_errlist.

3.1.4.11 except.h

The following functions, macros, and classes are provided in `except.h`:

Topics

Name	Description

__throwExceptionName (see page 840)	**Header File**
	except.h
	Syntax
	`extern char * _RTLENTRY __ThrowExceptionName();`
	`#define __throwExceptionName __ThrowExceptionName()`
	Description
	Use this global variable to get the name of a thrown exception. The output for this variable is a printable character string.

__throwFileName (see page 840)	**Header File**
	except.h
	Syntax
	`extern char * _RTLENTRY __ThrowFileName();`
	`#define __throwFileName __ThrowFileName()`
	Description
	Use this global variable to get the name of a thrown exception. The output for this variable is a printable character string.
	To get the file name for a thrown exception with __throwFileName, you must compile the module with the -xp compiler option.

__throwLineNumber (see page 840)	**Header File**
	except.h
	Syntax
	`extern unsigned _RTLENTRY __ThrowLineNumber();`
	`#define __throwLineNumber __ThrowLineNumber()`
	Description
	Use this global variable to get the name of a thrown exception. The output for this variable is a printable character string.
	To get the line number for a thrown exception with __throwLineNumber, you must compile the module with the -xp compiler option.

set_terminate (see page 840)	**Header File**
	except.h
	Syntax
	`typedef void (*terminate_handler)();`
	`terminate_handler set_terminate(terminate_handler t_func);`
	Description
	set_terminate lets you install a function that defines the program's termination behavior when a handler for the exception cannot be found. The actions are defined in t_func, which is declared to be a function of type terminate_handler. A terminate_handler type, defined in except.h, is a function that takes no arguments, and returns void.
	By default, an exception for which no handler can be found results in the program calling the terminate function. This will normally result in a call to abort. The program then ends with the message Abnormal... more (see page 840)

set_unexpected (see page 841)	**Header File**
	except.h
	Syntax
	`typedef void ( * unexpected_handler )();`
	`unexpected_handler set_unexpected(unexpected_handler unexpected_func);`
	Description
	set_unexpected lets you install a function that defines the program's behavior when a function throws an exception not listed in its exception specification. The actions are defined in unexpected_func, which is declared to be a function of type unexpected_handler. An unexpected_handler type, defined in except.h, is a function that takes no arguments, and returns void.
	By default, an unexpected exception causes unexpected to be called. If is defined, it is subsequently called by unexpected. Program control is then turned over to the user-defined unexpected_func. Otherwise, terminate... more (see page 841)

terminate (see page 841)	**Header File** except.h **Syntax** `void terminate();` **Description** The function terminate can be called by unexpected or by the program when a handler for an exception cannot be found. The default action by terminate is to call abort. Such a default action causes immediate program termination. You can modify the way that your program will terminate when an exception is generated that is not listed in the exception specification. If you do not want the program to terminate with a call to abort, you can instead define a function to be called. Such a function (called a terminate_handler) will be called... more (see page 841)
unexpected (see page 842)	**Header File** except.h **Syntax** `void unexpected();` **Description** The unexpected function is called when a function throws an exception not listed in its exception specification. The program calls unexpected, which by default calls any user-defined function registered by set_unexpected. If no function is registered with set_unexpected, the unexpected function then calls terminate. **Return Value** None, although unexpected may throw an exception.

3.1.4.11.1 __throwExceptionName

Header File

except.h

Syntax

```
extern char * _RTLENTRY __ThrowExceptionName();
#define __throwExceptionName __ThrowExceptionName()
```

Description

Use this global variable to get the name of a thrown exception. The output for this variable is a printable character string.

3.1.4.11.2 __throwFileName

Header File

except.h

Syntax

```
extern char * _RTLENTRY __ThrowFileName();
#define __throwFileName __ThrowFileName()
```

Description

Use this global variable to get the name of a thrown exception. The output for this variable is a printable character string.

To get the file name for a thrown exception with __throwFileName, you must compile the module with the -xp compiler option.

3.1.4.11.3 __throwLineNumber

Header File

except.h

Syntax

```
extern unsigned _RTLENTRY __ThrowLineNumber();
#define __throwLineNumber __ThrowLineNumber()
```

Description

Use this global variable to get the name of a thrown exception. The output for this variable is a printable character string.

To get the line number for a thrown exception with __throwLineNumber, you must compile the module with the -xp compiler option.

3.1.4.11.4 set_terminate

Header File

except.h

Syntax

```
typedef void (*terminate_handler)();
terminate_handler set_terminate(terminate_handler t_func);
```

Description

set_terminate lets you install a function that defines the program's termination behavior when a handler for the exception cannot be found. The actions are defined in t_func, which is declared to be a function of type terminate_handler. A terminate_handler type, defined in except.h, is a function that takes no arguments, and returns void.

By default, an exception for which no handler can be found results in the program calling the terminate function. This will normally result in a call to abort. The program then ends with the message Abnormal program termination. If you want some function other than abort to be called by the terminate function, you should define your own t_func function. Your t_func function is installed by set_terminate as the termination function. The installation of t_func lets you implement any actions that are not taken by abort.

Return Value

The previous function given to set_terminate will be the return value.

The definition of t_func must terminate the program. Such a user-defined function must not return to its caller, the terminate function. An attempt to return to the caller results in undefined program behavior. It is also an error for t_func to throw an exception.

3.1.4.11.5 set_unexpected

Header File

except.h

Syntax

```
typedef void ( * unexpected_handler )();
unexpected_handler set_unexpected(unexpected_handler unexpected_func);
```

Description

set_unexpected lets you install a function that defines the program's behavior when a function throws an exception not listed in its exception specification. The actions are defined in unexpected_func, which is declared to be a function of type unexpected_handler. An unexpected_handler type, defined in except.h, is a function that takes no arguments, and returns void.

By default, an unexpected exception causes unexpected to be called. If is defined, it is subsequently called by unexpected. Program control is then turned over to the user-defined unexpected_func. Otherwise, terminate is called.

Return Value

The previous function given to set_unexpected will be the return value.

The definition of unexpected_func must not return to its caller, the unexpected function. An attempt to return to the caller results in undefined program behavior.

unexpected_func can also call abort, exit, or terminate.

3.1.4.11.6 terminate

Header File

except.h

Syntax

```
void terminate();
```

Description

The function terminate can be called by unexpected or by the program when a handler for an exception cannot be found. The default action by terminate is to call abort. Such a default action causes immediate program termination.

You can modify the way that your program will terminate when an exception is generated that is not listed in the exception specification. If you do not want the program to terminate with a call to abort, you can instead define a function to be called. Such a function (called a terminate_handler) will be called by terminate if it is registered with set_terminate.

Return Value

None.

3.1.4.11.7 unexpected

Header File

except.h

Syntax

```
void unexpected();
```

Description

The unexpected function is called when a function throws an exception not listed in its exception specification. The program calls unexpected, which by default calls any user-defined function registered by set_unexpected. If no function is registered with set_unexpected, the unexpected function then calls terminate.

Return Value

None, although unexpected may throw an exception.

3.1.4.12 fastmath.h

The following functions, macros, and classes are provided in `fastmath.h`:

Topics

Name	Description
Using fastmath math routines (see page 842)	**Header File** fastmath.h **Category** Math Routines **Description** The FastMath routines are high performance math routines that don't check for most error conditions and never call matherr. They are coded for maximum speed. These functions are never exported from the RTLDLL, which means that they always get linked directly into the PE file that is being created. When you include fastmath.h, the following math functions are remapped to these fastmath functions.

3.1.4.12.1 Using fastmath math routines

Header File

fastmath.h

Category

Math Routines

Description

The FastMath routines are high performance math routines that don't check for most error conditions and never call matherr. They are coded for maximum speed. These functions are never exported from the RTLDLL, which means that they always get linked directly into the PE file that is being created.

When you include fastmath.h, the following math functions are remapped to these fastmath functions.

Math Routine	Fastmath Routine	Math Routine	Fastmath Routine
acos	_fm_acos	asin	_fm_asin
atan	_fm_atan	atan2	_fm_atan2
cos	_fm_cos	cosh	_fm_cosh
exp	_fm_exp	fabs	_fm_fabs
asin	_fm_asin	atan	_fm_atan
atan2	_fm_atan2	cos	_fm_cos
cosh	_fm_cosh	exp	_fm_exp
fabs	_fm_fabs	frexp	_fm_frexp
hypot	_fm_hypot	ldexp	_fm_ldexp
log	_fm_log	log10	_fm_log10
sin	_fm_sin	sinh	_fm_sinh
sqrt	_fm_sqr	tan	_fm_tan
tanh	_fm_tanh	sincos	_fm_sincos
acosl	_fm_acosl	asinl	_fm_asinl
atan2l	_fm_atan2l	atanl	_fm_atanl
coshl	_fm_coshl	cosl	_fm_cosl
expl	_fm_expl	fabsl	_fm_fabsl
frexpl	_fm_frexpl	hypotl	_fm_hypotl
ldexpl	_fm_ldexpl	log10l	_fm_log10l
logl	_fm_logl	sinhl	_fm_sinhl
sinl	_fm_sinl	sqrtl	_fm_sqrtl
tanhl	_fm_tanhl	tanl	_fm_tanl
sincosl	_fm_sincosl	atanhl	_fm_atanhl
acoshl	_fm_acoshl	asinhl	_fm_asinhl

If you don't want the standard C function names remapped to the FastMath versions, then define _FM_NO_REMAP. The FastMath routines can still be called with their _fm_xxx names.

The following additional functions are available in FastMath; they are not directly supported in the regular RTL:

```
void _FMAPI _fm_sincos(double __a, double *__x, double *__y);
void _FMAPI _fm_sincosl(long double __a, long double *__x, long double *__y);
long double _FMAPI _fm_atanhl (long double __x);
```

```
long double _FMAPI _fm_acoshl (long double __x);
long double _FMAPI _fm_asinhl (long double __x);
__inline void _fm_fwait(void)
unsigned int _FMAPI _fm_init(void);
```

_fm_fwait is a special inline function that performs an intrinsic FWAIT instruction.

_Fm_init is a function that can be called to mask all fpu exceptions prior to using the FastMath routines.

3.1.4.13 fcntl.h

The following functions, macros, and classes are provided in `fcntl.h`:

Topics

Name	Description
O_xxxx #defines (see page 845)	**Header File** fcntl.h **Description** These #defines are bit definitions for a file-access argument. These RTL file-open functions use some (not all) of these definitions: • fdopen • fopen • freopen • _fsopen • open • _rtl_open • sopen sopen also uses file-sharing symbolic constants in the file-access argument.
_fmode (see page 847)	**Header File** fcntl.h **Syntax** `extern int _fmode;` **Description** _fmode determines in which mode (text or binary) files will be opened and translated. The value of _fmode is O_TEXT by default, which specifies that files will be read in text mode. If _fmode is set to O_BINARY, the files are opened and read in binary mode. (O_TEXT and O_BINARY are defined in fcntl.h.) In text mode, carriage-return/linefeed (CR/LF) combinations are translated to a single linefeed character (LF) on input. On output, the reverse is true: LF characters are translated to CR/LF combinations. In binary mode, no such translation occurs. You can... more (see page 847)

_pipe (see page 847)	**Header File** io.h, fcntl.h **Category** Input/output Routines **Syntax** `int _pipe(int *handles, unsigned int size, int mode);` **Description** Creates a read/write pipe. The _pipe function creates an anonymous pipe that can be used to pass information between processes. The pipe is opened for both reading and writing. Like a disk file, a pipe can be read from and written to, but it does not have a name or permanent storage associated with it; data written to and from the pipe exist only in a memory buffer managed by the operating system. The read handle is returned to handles[0], and the write... more (see page 847)

open, _wopen (see page 849)	**Header File**
	io.h, fcntl.h
	Category
	Input/output Routines
	Prototype
	`int open(const char *path, int access [, unsigned mode]);`
	`int _wopen(const wchar_t *path, int access [, unsigned mode]);`
	Description
	Opens a file for reading or writing.
	open opens the file specified by path, then prepares it for reading and/or writing as determined by the value of access.
	To create a file in a particular mode, you can either assign to the global variable _fmode or call open with the O_CREAT and O_TRUNC options ORed with the translation mode desired.
	`open("XMP",O_CREAT|O_TRUNC|O_BINARY,S_IREAD)`
	creates a binary-mode, read-only file named XMP, truncating its length to 0... more (see page 849)

_sopen, _wsopen (see page 850)	**Header File**
	fcntl.h, sys\stat.h, share.h, io.h, stdio.h
	Category
	Input/output Routines
	Prototype
	`int _sopen(char *path, int access, int shflag[, int mode]);`
	`int _wsopen(wchar_t *path, int access, int shflag[, int mode]);`
	Description
	Opens a shared file.
	_sopen opens the file given by path and prepares it for shared reading or writing, as determined by access, shflag, and mode.
	_wsopen is the Unicode version of _sopen. The Unicode version accepts a filename that is a wchar_t character string. Otherwise, the functions perform identically.
	For _sopen, access is constructed by ORing flags bitwise from the following lists:
	Read/write flags
	You can use only one... more (see page 850)

3.1.4.13.1 O_xxxx #defines

Header File

fcntl.h

Description

These #defines are bit definitions for a file-access argument.

These RTL file-open functions use some (not all) of these definitions:

- fdopen
- fopen

- freopen
- _fsopen
- open
- _rtl_open
- sopen

sopen also uses file-sharing symbolic constants in the file-access argument.

	Constant	Description
Read/Write flag		
	O_RDONLY	Open for reading only
	O_WRONLY	Open for writing only
	O_RDWR	Open for reading and writing
Other access flags		
	O_NDELAY	Not used; for UNIX compatibility.
	O_APPEND	Append to end of file
		If set, the file pointer is set to the end of the file prior to each write.
	O_CREAT	Create and open file
		If the file already exists, has no effect.
		If the file does not exist, the file is created.
	O_EXCL	Exclusive open: Used only with O_CREAT.
		If the file already exists, an error is returned.
	O_TRUNC	Open with truncation
		If the file already exists, its length is truncated to 0. The file attributes remain unchanged.
Binary-mode/Text-mode flags		
	O_BINARY	No translation: Explicitly opens the file in binary mode
	O_TEXT	CR-LF translation: Explicitly opens the file in text mode
Additional values available using _rtl_open		
	O_NOINHERIT	Child processes inherit file
	O_DENYALL	Error if opened for read/write
	O_DENYWRITE	Error if opened for write
	O_DENYREAD	Error if opened for read
	O_DENYNONE	Allow concurrent access

Note: Only one of the O_DENYxxx options can be included in a single open. These file-sharing attributes are in addition to any locking performed on the files.

Do not modify		
	O_CHANGED	Special DOS read-only bit
	O_DEVICE	Special DOS read-only bit

3.1.4.13.2 _fmode

Header File

fcntl.h

Syntax

```
extern int _fmode;
```

Description

_fmode determines in which mode (text or binary) files will be opened and translated. The value of _fmode is O_TEXT by default, which specifies that files will be read in text mode. If _fmode is set to O_BINARY, the files are opened and read in binary mode. (O_TEXT and O_BINARY are defined in fcntl.h.)

In text mode, carriage-return/linefeed (CR/LF) combinations are translated to a single linefeed character (LF) on input. On output, the reverse is true: LF characters are translated to CR/LF combinations.

In binary mode, no such translation occurs.

You can override the default mode as set by _fmode by specifying a t (for text mode) or b (for binary mode) in the argument type in the library functions fopen, fdopen, and freopen. Also, in the function open, the argument access can include either O_BINARY or O_TEXT, which will explicitly define the file being opened (given by the path argument to the open function) to be in either binary or text mode.

3.1.4.13.3 _pipe

Header File

io.h, fcntl.h

Category

Input/output Routines

Syntax

```
int _pipe(int *handles, unsigned int size, int mode);
```

Description

Creates a read/write pipe.

The _pipe function creates an anonymous pipe that can be used to pass information between processes. The pipe is opened for both reading and writing. Like a disk file, a pipe can be read from and written to, but it does not have a name or permanent storage associated with it; data written to and from the pipe exist only in a memory buffer managed by the operating system.

The read handle is returned to handles[0], and the write handle is returned to handles[1]. The program can use these handles in subsequent calls to read, write, dup, dup2, or close. When all pipe handles are closed, the pipe is destroyed.

The size of the internal pipe buffer is size. A recommended minimum value is 512 bytes.

The translation mode is specified by mode, as follows:

O_BINARY	The pipe is opened in binary mode
O_TEXT	The pipe is opened in text mode

If mode is zero, the translation mode is determined by the external variable _fmode.

Return Value

On success, _pipe returns 0 and returns the pipe handles to handles[0] and handles[1].

On error, it returns -1 and sets errno to one of the following values:

EMFILE	Too many open files
ENOMEM	Out of memory

Example

```
/*
 There are two short programs here.  SEND spawns a child
 process, RECEIVE.  Each process holds one end of a
 pipe.  The parent transmits its command-line argument
 to the child, which prints the string and exits.
 IMPORTANT:  The parent process must be linked with
 the \32bit\fileinfo.obj file.  The code in fileinfo
 enables a parent to share handles with a child.
 Without this extra information, the child cannot use
 the handle it receives.
*/
/* SEND */
#include <fcntl.h>            // _pipe()
#include <io.h>             // write()
#include <process.h>          // spawnl() cwait()
#include <stdio.h>           // puts() perror()
#include <stdlib.h>           // itoa()
#include <string.h>           // strlen()
#define DECIMAL_RADIX 10      // for atoi()
enum PIPE_HANDLES { IN, OUT };  // to index the array of handles
int main(int argc, char *argv[])
{
  int handles[2];           // in- and
//outbound pipe handles
  char handleStr[10];         // a handle
//stored as a string
  int pid;
  // system's ID for child process
  if (argc <= 1)
  {
    puts("No message to send.");
    return(1);
  }
  if (_pipe(handles, 256, O_TEXT) != 0)
  {
    perror("Cannot create the pipe");
    return(1);
  }
  // store handle as a string for passing on the command line
  itoa(handles[IN], handleStr, DECIMAL_RADIX);
  // create the child process, passing it the inbound pipe handle
     spawnl(P_NOWAIT, "receive.exe", "receive.exe", handleStr, NULL);
  // transmit the message
  write(handles[OUT], argv[1], strlen(argv[1])+1);
  // when done with the pipe, close both handles
  close(handles[IN]);
  close(handles[OUT]);
```

```
  // wait for the child to finish
  wait(NULL);
  return(0);
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.13.4 open, _wopen

Header File

io.h, fcntl.h

Category

Input/output Routines

Prototype

```
int open(const char *path, int access [, unsigned mode]);
```

```
int _wopen(const wchar_t *path, int access [, unsigned mode]);
```

Description

Opens a file for reading or writing.

open opens the file specified by path, then prepares it for reading and/or writing as determined by the value of access.

To create a file in a particular mode, you can either assign to the global variable _fmode or call open with the O_CREAT and O_TRUNC options ORed with the translation mode desired.

```
open("XMP",O_CREAT|O_TRUNC|O_BINARY,S_IREAD)
```

creates a binary-mode, read-only file named XMP, truncating its length to 0 bytes if it already existed.

For open, access is constructed by bitwise ORing flags from the following lists. Only one flag from the first list can be used (and one must be used); the remaining flags can be used in any logical combination.

These symbolic constants are defined in fcntl.h.

O_RDONLY	Open for reading only.
O_WRONLY	Open for writing only.
O_RDWR	Open for reading and writing.

O_NDELAY	Not used; for UNIX compatibility.
O_APPEND	If set, the file pointer will be set to the end of the file prior to each write.
O_CREAT	If the file exists, this flag has no effect. If the file does not exist, the file is created, and the bits of mode are used to set the file attribute bits as in chmod.
O_TRUNC	If the file exists, its length is truncated to 0. The file attributes remain unchanged.

O_EXCL	Used only with O_CREAT. If the file already exists, an error is returned.
O_BINARY	Can be given to explicitly open the file in binary mode.
O_TEXT	Can be given to explicitly open the file in text mode.

If neither O_BINARY nor O_TEXT is given, the file is opened in the translation mode set by the global variable _fmode.

If the O_CREAT flag is used in constructing access, you need to supply the mode argument to open from the following symbolic constants defined in sys\stat.h.

S_IWRITE	Permission to write
S_IREAD	Permission to read
S_IREAD|S_IWRITE	Permission to read and write

Return Value

On success, open returns a nonnegative integer (the file handle). The file pointer, which marks the current position in the file, is set to the beginning of the file.

On error, open returns -1 and the global variable errno is set to one of the following values:

EACCES	Permission denied
EINVACC	Invalid access code
EMFILE	Too many open files
ENOENT	No such file or directory

Example

```
#include <string.h>
#include <stdio.h>
#include <fcntl.h>
#include <io.h>
int main(void)
{
   int handle;
   char msg[] = "Hello world";
   if ((handle = open("TEST.$$$", O_CREAT | O_TEXT)) == -1)
   {
      perror("Error:");
      return 1;
   }
   write(handle, msg, strlen(msg));
   close(handle);
   return 0;
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
open	+	+		
_wopen		NT only		

3.1.4.13.5 _sopen, _wsopen

Header File

fcntl.h, sys\stat.h, share.h, io.h, stdio.h

Category

Input/output Routines

Prototype

```
int _sopen(char *path, int access, int shflag[, int mode]);
int _wsopen(wchar_t *path, int access, int shflag[, int mode]);
```

Description

Opens a shared file.

_sopen opens the file given by path and prepares it for shared reading or writing, as determined by access, shflag, and mode.

_wsopen is the Unicode version of _sopen. The Unicode version accepts a filename that is a wchar_t character string. Otherwise, the functions perform identically.

For _sopen, access is constructed by ORing flags bitwise from the following lists:

Read/write flags

You can use only one of the following flags:

O_RDONLY	Open for reading only.
O_WRONLY	Open for writing only.
O_RDWR	Open for reading and writing.

Other access flags

You can use any logical combination of the following flags:

O_NDELAY	Not used; for UNIX compatibility.
O_APPEND	If set, the file pointer is set to the end of the file prior to each write.
O_CREA	If the file exists, this flag has no effect. If the file does not exist, the file is created, and the bits of mode are used to set the file attribute bits as in chmod.
O_TRUNC	If the file exists, its length is truncated to 0. The file attributes remain unchanged.
O_EXCL	Used only with O_CREAT. If the file already exists, an error is returned.
O_BINARY	This flag can be given to explicitly open the file in binary mode.
O_TEXT	This flag can be given to explicitly open the file in text mode.
O_NOINHERIT	The file is not passed to child programs.

Note: These O_... symbolic constants are defined in fcntl.h.

If neither O_BINARY nor O_TEXT is given, the file is opened in the translation mode set by the global variable _fmode.

If the O_CREAT flag is used in constructing access, you need to supply the mode argument to _sopen from the following symbolic constants defined in sys\stat.h.

S_IWRITE	Permission to write
S_IREAD	Permission to read
S_IREAD|S_IWRITE	Permission to read/write

shflag specifies the type of file-sharing allowed on the file path. Symbolic constants for shflag are defined in share.h.

SH_COMPAT	Sets compatibility mode.
SH_DENYRW	Denies read/write access
SH_DENYWR	Denies write access
SH_DENYRD	Denies read access
SH_DENYNONE	Permits read/write access
SH_DENYNO	Permits read/write access

Return Value

On success, _sopen returns a nonnegative integer (the file handle), and the file pointer (that marks the current position in the file) is set to the beginning of the file.

On error, it returns -1, and the global variable errno is set to

EACCES	Permission denied
EINVACC	Invalid access code
EMFILE	Too many open files
ENOENT	Path or file function not found

Example

```
#include <io.h>
#include <fcntl.h>
#include <sys\stat.h>
#include <process.h>
#include <share.h>
#include <stdio.h>
#include <stdlib.h>
int main(void)
{
   int handle,
       handle1;
   handle = sopen("c:\\autoexec.bat", O_RDONLY, SH_DENYWR, S_IREAD);
   if      (handle == -1)
   {
     perror (sys_errlist[errno]);
     exit (1);
   }
   if (!handle)
   {
      printf("sopen failed\n");
      exit(1);
   }
   /*      Attempt sopen for write.
   */
   handle1 = sopen("c:\\autoexec.bat", O_RDONLY, SH_DENYWR, S_IREAD);
   if      (handle1 == -1)
   {
     perror (sys_errlist[errno]);
     exit (1);
   }
   if (!handle1)
   {
      printf("sopen failed\n");
      exit(1);
   }
   close (handle);
   close (handle1);
```

```
    return 0;
}
```

3.1.4.14 float.h

The following functions, macros, and classes are provided in `float.h`:

Topics

Name	Description
CW_DEFAULT #define (see page 856)	**Header File** float.h **Description** Default control word for 80x87 math coprocessor.

_chgsign, _chgsignl (see page 856)	**Header File**
	float.h
	Category
	Math Routintes
	Prototype
	`double _chgsign(double d);`
	`long double _chgsignl(long double ld);`
	Description
	Reverses the sign of a double-precision floating-point argument, d.
	_chgsignl is the **long double** version; it takes a **long double** argument and returns a **long double** result.
	Return Value
	Returns a value of the same magnitude and exponent as the argument, but with the opposite sign. There is no error return value.
	Portability

_clear87, _clearfp (see page 857)	**Header File**
	float.h
	Category
	Math Routines
	Prototype
	`unsigned int _clear87 (void);`
	`unsigned int _clearfp (void);`
	Description
	Clears the floating-point status word.
	_clear87 clears the floating-point status word, which is a combination of the 80x87 status word and other conditions detected by the 80x87 exception handler.
	_clearfp is identical to _clear87 and is for Microsoft compatibility.
	Return Value
	The bits in the value returned indicate the floating-point status before it was cleared. For information on the status word, refer to the constants defined in float.h.
	Example

_control87, _controlfp (see page 858)	**Header File**
	float.h
	Category
	Math Routines
	Prototype
	`unsigned int _control87(unsigned int newcw, unsigned int mask);`
	`unsigned int _controlfp(unsigned int newcw, unsigned int mask);`
	Description
	Manipulates the floating-point control word.
	_control87 retrieves or changes the floating-point control word.
	The floating-point control word is an **unsigned int** that, bit by bit, specifies certain modes in the floating-point package; namely, the precision, infinity, and rounding modes. Changing these modes lets you mask or unmask floating-point exceptions.
	_control87 matches the bits in mask to the bits in newcw. If a mask bit equals 1, the corresponding bit in newcw contains the new value... more (see page 858)

_copysign, _copysignl (see page 859)	**Header File**
	float.h
	Category
	Math Routines
	Prototype
	`double _copysign(double da, double db);`
	`long double _copysignl(long double lda, long double ldb);`
	Description
	Returns the double-precision floating point argument da, with the same sign as the double-precision floating-point argument db.
	_copysignl is the **long double** version; it takes a **long double** argument and returns a **long double** result.
	Return Value
	Returns the first value with the same magnitude and exponent, but with the sign of the second value. There is no error value returned.
	Portability

_finite, _finitel (see page 859)	**Header File**
	float.h
	Category
	Math Routines
	Prototype
	`int _finite(double d);`
	`int _finitel(long double ld);`
	Description
	Determines whether a given double-precision floating point value d is finite.
	_finitel is the **long double** version; it takes a **long double** argument.
	Return Value
	Returns non-zero if the argument is finite, and 0 if it is not.
	Portability

_fpclass, _fpclassl (see page 860)	**Header File**
	float.h
	Category
	Math Routines
	Prototype
	`int _fpclass(double d);`
	`int _fpclassl(long double ld);`
	Description
	Returns an integer value representing the type (class) of an IEEE real for doubles. This value contains information on the floating-point class of the argument.
	_fpclassl is the **long double** version; it takes a **long double** argument and returns the type (class) of an IEEE real for long doubles.
	Return Value
	Returns an integer value that indicates the floating-point class of its argument. The possible values, which are listed in the table below, are defined in FLOAT.H.
	Portability

_fpreset (see page 860)	**Header File** float.h **Category** Math Routines **Prototype** `void _fpreset(void);` **Description** Reinitializes floating-point math package. _fpreset reinitializes the floating-point math package. This function is usually used in conjunction with system or the exec... or spawn... functions. It is also used to recover from floating-point errors before calling longjmp. **Note:** If an 80x87 coprocessor is used in a program a child process (executed by the system, or by an exec... or spawn... function) might alter the parent process' floating-point state. • If you use an 80x87 take the following precautions: • Do not call system or an exec... or spawn... function while a... more (see page 860)

_isnan, _isnanl (see page 861)	**Header File**
	float.h
	Category
	Classification Routines, Math Routines
	Prototype
	`int _isnan(double d);`
	`int _isnanl(long double ld);`
	Description
	Tests whether a given double-precision floating-point value d is a NaN.
	_isnanl is the **long double** version; it takes a **long double** argument.
	Return Value
	Returns a nonzero value (TRUE) if the value passed in is a NaN; otherwise it returns 0 (FALSE). The non-zero return value corresponds to either _FPCLASS_SNAN, if the NaN is of the signaling type, or _FPCLASS_QNAN, if the NaN is of the quiet type. The values for _FPCLASS_SNAN and _FPCLASS_QNAN are in float.h.
	Portability

_logb, _logbl (see page 862)	**Header File**
	float.h
	Category
	Math Routines
	Prototype
	`double _logb(double d);`
	`long double _logbl(long double ld);`
	Description
	Extracts the exponential value of a double-precision floating-point argument. If the argument is denormalized, it is treated as if it were normalized.
	_logbl is the **long double** version; it takes a **long double** argument and returns a **long double** result.
	Return Value
	Returns the unbiased exponent of the value passed in.
	Portability

_nextafter, _nextafterl (see page 862)	**Header File**
	float.h
	Category
	Math Routines
	Prototype
	`double _nextafter(double da, double db);`
	`long double _nextafterl(long double lda, long double ldb);`
	Description
	Takes two doubles (da and db) and returns the closest representable neighbor of da in the direction toward db.
	If da == db, _nextafter returns da, with no exception triggered. If either da or db is a quiet NaN, then the return value is one or the other of the input NaNs.
	_nextafterl is the **long double** version; it takes a **long double** argument and returns a **long double** result.
	Return Value
	Returns the closest representable neighbor of... more (see page 862)

_scalb, _scalbl (see page 863)	**Header File**
	float.h
	Category
	Math Routines
	Prototype
	`double _scalb(double d, long exp);`
	`long double _scalbl(long double ld, long exp);`
	Description
	Scales the argument d by a power of 2.
	_scalbl is the **long double** version; it takes a **long double** argument and returns a **long double** result.
	Return Value
	Returns an exponential value if successful. On overflow (depending on the sign of the argument), the function returns +/– HUGE_VAL; the ERRNO variable is set to ERANGE.
	Portability

_status87, _statusfp (see page 863)	**Header File**
	float.h
	Category
	Math Routines
	Prototype
	`unsigned int _status87(void);`
	`unsigned int _statusfp(void);`
	Description
	Gets floating-point status.
	_status87 gets the floating-point status word, which is a combination of the 80x87 status word and other conditions detected by the 80x87 exception handler.
	_statusfp is identical to _status87 and is for Microsoft compatibility.
	Return Value
	The bits in the return value give the floating-point status. See float.h for a complete definition of the bits returned by _status87 and _status87.
	Portability

3.1.4.14.1 CW_DEFAULT #define

Header File

float.h

Description

Default control word for 80x87 math coprocessor.

3.1.4.14.2 _chgsign, _chgsignl

Header File

float.h

Category

Math Routintes

Prototype

```
double _chgsign(double d);
long double _chgsignl(long double ld);
```

Description

Reverses the sign of a double-precision floating-point argument, d.

_chgsignl is the **long double** version; it takes a **long double** argument and returns a **long double** result.

Return Value

Returns a value of the same magnitude and exponent as the argument, but with the opposite sign. There is no error return value.

Portability

	POSIX	Win32	ANSI C	ANSI C++
_chgsign		+		
_chgsignl		+		

3.1.4.14.3 _clear87, _clearfp

Header File

float.h

Category

Math Routines

Prototype

```
unsigned int _clear87 (void);
unsigned int _clearfp (void);
```

Description

Clears the floating-point status word.

_clear87 clears the floating-point status word, which is a combination of the 80x87 status word and other conditions detected by the 80x87 exception handler.

_clearfp is identical to _clear87 and is for Microsoft compatibility.

Return Value

The bits in the value returned indicate the floating-point status before it was cleared. For information on the status word, refer to the constants defined in float.h.

Example

```
#include <stdio.h>
#include <float.h>
int main(void)
{
```

```
    float x;
    double y = 1.5e-100;
    printf("\nStatus 87 before error: %X\n", _status87());
    x = y; /* create underflow and precision loss */
    printf("Status 87 after  error: %X\n", _status87());
    _clear87();
    printf("Status 87 after  clear: %X\n", _status87());
    y = x;
    return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.14.4 _control87, _controlfp

Header File

float.h

Category

Math Routines

Prototype

```
unsigned int _control87(unsigned int newcw, unsigned int mask);
```

```
unsigned int _controlfp(unsigned int newcw, unsigned int mask);
```

Description

Manipulates the floating-point control word.

_control87 retrieves or changes the floating-point control word.

The floating-point control word is an **unsigned int** that, bit by bit, specifies certain modes in the floating-point package; namely, the precision, infinity, and rounding modes. Changing these modes lets you mask or unmask floating-point exceptions.

_control87 matches the bits in mask to the bits in newcw. If a mask bit equals 1, the corresponding bit in newcw contains the new value for the same bit in the floating-point control word, and _control87 sets that bit in the control word to the new value.

Here is a simple illustration:

Original control word:	0100	0011	0110	0011	
mask:		1000	0001	0100	1111
newcw:		1110	1001	0000	0101
Changing bits:		1xxx	xxx1	x0xx	0101

If mask equals 0, _control87 returns the floating-point control word without altering it.

_controlfp is for Microsoft compatibility. _controlfp is identical to _control87 except that it always removes (turns off) the EM_DEMORMAL bit from the mask parameter.

Return Value

The bits in the value returned reflect the new floating-point control word. For a complete definition of the bits returned by _control87, see the header file float.h.

Portability

	POSIX	Win32	ANSI C	ANSI C++

_copysignl		+		

3.1.4.14.6 _finite, _finitel

Header File

float.h

Category

Math Routines

Prototype

```
int _finite(double d);
int _finitel(long double ld);
```

Description

Determines whether a given double-precision floating point value d is finite.

_finitel is the **long double** version; it takes a **long double** argument.

Return Value

Returns non-zero if the argument is finite, and 0 if it is not.

Portability

	POSIX	Win32	ANSI C	ANSI C++
_finite		+		
_finitel		+		

3.1.4.14.7 _fpclass, _fpclassl

Header File

float.h

Category

Math Routines

Prototype

```
int _fpclass(double d);
int _fpclassl(long double ld);
```

Description

Returns an integer value representing the type (class) of an IEEE real for doubles. This value contains information on the floating-point class of the argument.

_fpclassl is the **long double** version; it takes a **long double** argument and returns the type (class) of an IEEE real for long doubles.

Return Value

Returns an integer value that indicates the floating-point class of its argument. The possible values, which are listed in the table below, are defined in FLOAT.H.

Portability

	POSIX	Win32	ANSI C	ANSI C++
_fpclass		+		
_fpclassl		+		

3.1.4.14.8 _fpreset

Header File

float.h

Category

Math Routines

Prototype

```
void _fpreset(void);
```

Description

Reinitializes floating-point math package.

_fpreset reinitializes the floating-point math package. This function is usually used in conjunction with system or the exec... or spawn... functions. It is also used to recover from floating-point errors before calling longjmp.

Note: If an 80x87 coprocessor is used in a program a child process (executed by the system, or by an exec... or spawn... function) might alter the parent process' floating-point state.

- If you use an 80x87 take the following precautions:
- Do not call system or an exec... or spawn... function while a floating-point expression is being evaluated.

Call _fpreset to reset the floating-point state after using system exec... or spawn... if there is any chance that the child process performed a floating-point operation with the 80x87.

Return Value

None.

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.14.9 _isnan, _isnanl

Header File

float.h

Category

Classification Routines, Math Routines

Prototype

```
int _isnan(double d);
int _isnanl(long double ld);
```

Description

Tests whether a given double-precision floating-point value d is a NaN.

_isnanl is the **long double** version; it takes a **long double** argument.

Return Value

Returns a nonzero value (TRUE) if the value passed in is a NaN; otherwise it returns 0 (FALSE). The non-zero return value corresponds to either _FPCLASS_SNAN, if the NaN is of the signaling type, or _FPCLASS_QNAN, if the NaN is of the quiet type. The values for _FPCLASS_SNAN and _FPCLASS_QNAN are in float.h.

Portability

	POSIX	Win32	ANSI C	ANSI C++
_isnan		+		
_isnanl		+		

3.1.4.14.10 _logb, _logbl

Header File

float.h

Category

Math Routines

Prototype

```
double _logb(double d);
long double _logbl(long double ld);
```

Description

Extracts the exponential value of a double-precision floating-point argument. If the argument is denormalized, it is treated as if it were normalized.

_logbl is the **long double** version; it takes a **long double** argument and returns a **long double** result.

Return Value

Returns the unbiased exponent of the value passed in.

Portability

	POSIX	Win32	ANSI C	ANSI C++
_logb		+		
_logbl		+		

3.1.4.14.11 _nextafter, _nextafterl

Header File

float.h

Category

Math Routines

Prototype

```
double _nextafter(double da, double db);
long double _nextafterl(long double lda, long double ldb);
```

Description

Takes two doubles (da and db) and returns the closest representable neighbor of da in the direction toward db.

If da == db, _nextafter returns da, with no exception triggered. If either da or db is a quiet NaN, then the return value is one or the other of the input NaNs.

_nextafterl is the **long double** version; it takes a **long double** argument and returns a **long double** result.

Return Value

Returns the closest representable neighbor of the first argument in the direction toward the second argument.

Portability

	POSIX	Win32	ANSI C	ANSI C++
_nextafter		+		
_nextafterl		+		

3.1.4.14.12 _scalb, _scalbl

Header File

float.h

Category

Math Routines

Prototype

```
double _scalb(double d, long exp);
long double _scalbl(long double ld, long exp);
```

Description

Scales the argument d by a power of 2.

_scalbl is the **long double** version; it takes a **long double** argument and returns a **long double** result.

Return Value

Returns an exponential value if successful. On overflow (depending on the sign of the argument), the function returns +/– HUGE_VAL; the ERRNO variable is set to ERANGE.

Portability

	POSIX	Win32	ANSI C	ANSI C++
_scalb		+		
_scalbl		+		

3.1.4.14.13 _status87, _statusfp

Header File

float.h

Category

Math Routines

Prototype

```
unsigned int _status87(void);
unsigned int _statusfp(void);
```

Description

Gets floating-point status.

_status87 gets the floating-point status word, which is a combination of the 80x87 status word and other conditions detected by

the 80x87 exception handler.

_statusfp is identical to _status87 and is for Microsoft compatibility.

Return Value

The bits in the return value give the floating-point status. See float.h for a complete definition of the bits returned by _status87 and _status87.

Portability

	POSIX	Win32	ANSI C	ANSI C++
_status87		+		
_statusfp		+		

3.1.4.15 io.h

The following functions, macros, and classes are provided in `io.h`:

Topics

Name	Description
_findclose (see page 873)	**Header File** io.h **Category** Directory Control Routines **Prototype** `int _findclose(long handle);` **Description** Closes the specified search handle and releases associated resources associated with previous calls to findfirst/findnext. The handle parameter is the search handle returned by the previous call to _findfirst. This function is provided for Microsoft compatibility. **Return Value** On success, returns 0. Otherwise, returns –1 and sets errno to: ENOENTFile specification that could not be matched **Portability**

_findfirst, __wfindfirst (see page 874)	**Header File**
	io.h, wchar.h
	Category
	Directory Control Routines
	Prototype
	`long _findfirst(char *filter, struct _finddata_t *fileinfo);`
	`long __wfindfirst(wchar_t *filter, struct _wfinddata_t *fileinfo);`
	Description
	Begins a search of a disk directory to find information about the first instance of a filename that matches a specified filter. The filter parameter is a string that specifies which files to return. Wildcards may be used in the filter. The fileinfo parameter is the file information buffer. If a matching file is found, the fileinfo structure is filled with the file-directory information.
	These functions are provided for Microsoft compatibility.
	Return Value
	On success, returns a unique... more (see page 874)

_findfirsti64, _wfindfirsti64 (see page 875)	**Header File**
	io.h, wchar.h
	Category
	Directory Control Routines
	Prototype
	`long _findfirsti64(char *filter, struct _finddatai64_t *fileinfo);`
	`long _wfindfirsti64(wchar_t *filter, struct _wfinddatai64_t *fileinfo);`
	Description
	Begins a search of a disk directory to find information about the first instance of a filename that matches a specified filter. The filter parameter is a string that specifies which files to return. Wildcards may be used in the filter. The fileinfo parameter is the file information buffer. If a matching file is found, the fileinfo structure is filled with the file-directory information.
	These i64 versions are for 64 bit filesize use and are provided for Microsoft... more (see page 875)

_findnext, __wfindnext (see page 875)	**Header File**
	io.h, wchar.h
	Category
	Directory Control Routines
	Prototype
	`long _findnext(long handle, struct _finddata_t *fileinfo);`
	`long __wfindnext(long handle, struct _wfinddata_t *fileinfo);`
	Description
	Finds subsequent files, if any, that match the filter argument in a previous call to _findfirst/__wfindfirst. Then, _findnext/__wfindnext updates the fileinfo structure with the necessary information for continuing the search. One file name for each call to _tfindnext is returned until no more files are found in the directory matching the pathname (filter).
	The handle parameter is the search handle returned by a previous call to _findfirst. The fileinfo parameter is the file information buffer.
	These functions are... more (see page 875)

_findnexti64, _wfindnexti64 (see page 876)	**Header File**
	io.h, wchar.h
	Category
	Directory Control Routines
	Prototype
	`long _findnexti64(long handle, struct _finddatai64_t *fileinfo);`
	`__int64 _wfindnexti64(long handle, struct _wfinddata_t *fileinfo);`
	Description
	Finds subsequent files, if any, that match the filter argument in a previous call to _findfirsti64/_wfindfirsti64. Then, _findnexti64/_wfindnexti64 updates the fileinfo structure with the necessary information for continuing the search. One file name for each call to _tfindnext is returned until no more files are found in the directory matching the pathname (filter).
	The handle parameter is the search handle returned by a previous call to _findfirst. The fileinfo parameter is the file information buffer.
	These i64 versions... more (see page 876)

_get_osfhandle (see page 877)	**Header File** io.h **Category** Input/output Routines **Prototype** `long _get_osfhandle(int filehandle);` **Description** Associates file handles. The _get_osfhandle function associates an operating system file handle with an existing runtime file handle. The variable filehandle is the file handle of your program. **Return value** On success, _get_osfhandle returns an operating system file handle corresponding to the variable filehandle. On error, the function returns -1 and sets the global variable errno to

_open_osfhandle (see page 879)	**Header File** io.h **Category** Input/output Routines **Prototype** `int _open_osfhandle(long osfhandle, int flags);` **Description** Associates file handles. The _open_osfhandle function allocates a runtime file handle and sets it to point to the operating system file handle specified by osfhandle. The value flags is a bitwise OR combination of one or more of the following manifest constants (defined in fcntl.h):

_rtl_chmod, _wrtl_chmod (see page 880)	**Header File**
	io.h
	Category
	Input/output Routines
	Prototype
	`int _rtl_chmod(const char *path, int func [, int attrib]);`
	`int _wrtl_chmod(const wchar_t *path, int func, ... );`
	Description
	Gets or sets file attributes.
	Note: The _rtl_chmod function replaces _chmod
	which is obsolete_rtl_chmod can either fetch or set file attributes. If func is 0, _rtl_chmod returns the current attributes for the file. If func is 1, the attribute is set to attrib.
	attrib can be one of the following symbolic constants (defined in dos.h):

_rtl_close (see page 881)	**Header File** io.h **Category** Input/output Routines **Prototype** `int _rtl_close(int handle);` **Description** Closes a file. **Note:** This function replaces _close which is obsolete The _rtl_close function closes the file associated with handle, a file handle obtained from a call to creat, creatnew, creattemp, dup, dup2, open, _rtl_creat, or _rtl_open. It does not write a Ctrl-Z character at the end of the file. If you want to terminate the file with a Ctrl-Z, you must explicitly output one. **Return Value** On success, _rtl_close returns 0. On error (if it fails because handle is not the handle of a valid, open file), _rtl_close... more (see page 881)

_rtl_creat, _wrtl_creat (see page 882)	**Header File**
	io.h
	Category
	Input/output Routines
	Prototype
	`int _rtl_creat(const char *path, int attrib);`
	`int _wrtl_creat(const wchar_t *path, int attrib);`
	Description
	Creates a new file or overwrites an existing one.
	Note: The _rtl_creat function replaces _creat,
	which is obsolete_rtl_creat opens the file specified by path. The file is always opened in binary mode. Upon successful file creation, the file pointer is set to the beginning of the file. The file is opened for both reading and writing.
	If the file already exists its size is reset to 0. (This is essentially the same as deleting the file and creating a new... more (see page 882)

_rtl_open, _wrtl_open (see page 883)	**Header File**
	io.h
	Category
	Input/output Routines
	Prototype
	`int _rtl_open(const char *filename, int oflags);`
	`int _wrtl_open(const wchar_t *path, int oflags);`
	Description
	Opens a file for reading or writing.
	Note: The _rtl_open function replaces _open which is obsolete.
	_rtl_open opens the file specified by filename, then prepares it for reading or writing, as determined by the value of oflags. The file is always opened in binary mode.
	oflags uses the flags from the following two lists. Only one flag from List 1 can be used (and one must be used) and the flags in List 2 can be used in any logical... more (see page 883)

_rtl_read (see page 885)	**Header File** io.h **Category** Input/output Routines **Prototype** `int _rtl_read(int handle, void *buf, unsigned len);` **Description** Reads from file. **Note:** This function replaces _read which is obsolete. This function reads len bytes from the file associated with handle into the buffer pointed to by buf. When a file is opened in text mode, _rtl_read does not remove carriage returns. The argument handle is a file handle obtained from a creat, open, dup, or dup2 call. On disk files, _rtl_read begins reading at the current file pointer. When the reading is complete, it increments the file pointer by the number of bytes... more (see page 885)
_rtl_write (see page 886)	**Header File** io.h **Category** Input/output Routines **Prototype** `int _rtl_write(int handle, void *buf, unsigned len);` **Description** Writes to a file. **Note:** This function replaces _write which is obsolete. _rtl_write attempts to write len bytes from the buffer pointed to by buf to the file associated with handle. The maximum number of bytes that _rtl_write can write is UINT_MAX -1 (because UINT_MAX is the same as -1), which is the error return indicator for _rtl_write. UINT_MAX is defined in limits.h. _rtl_write does not translate a linefeed character (LF) to a CR/LF pair because all its files are binary files. If the number... more (see page 886)

access, _waccess (see page 887)	**Header File**
	io.h
	Category
	Input/output Routines
	Prototype
	`int access(const char *filename, int amode);`
	`int _waccess(const wchar_t *filename, int amode);`
	Description
	Determines accessibility of a file.
	access checks the file named by filename to determine if it exists, and whether it can be read, written to, or executed.
	The list of amode values is as follows:

chmod, _wchmod (see page 889)	**Header File**
	io.h
	Category
	Input/output Routines
	Prototype
	`int chmod(const char *path, int amode);`
	`int _wchmod(const wchar_t *path, int amode);`
	Description
	Changes file access mode.
	chmod sets the file-access permissions of the file given by path according to the mask given by amode. path points to a string.
	amode can contain one or both of the symbolic constants S_IWRITE and S_IREAD (defined in sys\stat.h).

chsize (see page 890)	**Header File** io.h **Category** Input/output Routines **Prototype** `int chsize(int handle, long size);` **Description** Changes the file size. chsize changes the size of the file associated with handle. It can truncate or extend the file, depending on the value of size compared to the file's original size. The mode in which you open the file must allow writing. If chsize extends the file, it will append null characters (\0). If it truncates the file, all data beyond the new end-of-file indicator is lost. **Return Value** On success, chsize returns 0. On failure, it returns -1 and the global variable errno is... more (see page 890)
close (see page 891)	**Header File** io.h **Category** Input/output Routines **Prototype** `int close(int handle);` **Description** Closes a file. The close function closes the file associated with handle, a file handle obtained from a call to creat, creatnew, creattemp, dup, dup2, open, _rtl_creat, or _rtl_open. It does not write a Ctrl-Z character at the end of the file. If you want to terminate the file with a Ctrl-Z, you must explicitly output one. **Return Value** Upon successful completion, close returns 0. On error (if it fails because handle is not the handle of a valid, open file), close returns a value of -1 and the... more (see page 891)

_creat, _wcreat (see page 892)	**Header File**
	io.h
	Category
	Input/output Routines
	Prototype
	`int creat(const char *path, int amode);`
	`int _wcreat(const wchar_t *path, int amode);`
	Description
	Creates a new file or overwrites an existing one.
	Note: Remember that a backslash in a path requires '\\'.
	creat creates a new file or prepares to rewrite an existing file given by path. amode applies only to newly created files.
	A file created with creat is always created in the translation mode specified by the global variable _fmode (O_TEXT or O_BINARY).
	If the file exists and the write attribute is set, creat truncates the file to a length of... more (see page 892)

creatnew (see page 893)	**Header File** io.h **Category** Input/output Routines **Prototype** `int creatnew(const char *path, int mode);` **Description** Creates a new file. creatnew is identical to _rtl_creat with one exception: If the file exists, creatnew returns an error and leaves the file untouched. The mode argument to creatnew can be zero or an OR-combination of any one of the following constants (defined in dos.h):
creattemp (see page 894)	**Header File** io.h **Category** Input/output Routines **Prototype** `int creattemp(char *path, int attrib);` **Description** Creates a unique file in the directory associated with the path name. A file created with creattemp is always created in the translation mode specified by the global variable _fmode (O_TEXT or O_BINARY). path is a path name ending with a backslash (\). A unique file name is selected in the directory given by path. The newly created file name is stored in the path string supplied. path should be long enough to hold the resulting file name. The file is not automatically deleted when the program... more (see page 894)
dup (see page 895)	**Header File** io.h **Category** Input/output Routines **Prototype** `int dup(int handle);` **Description** Duplicates a file handle. • dup creates a new file handle that has the following in common with the original file handle: • Same open file or device • Same file pointer (that is, changing the file pointer of one changes the other) • Same access mode (read, write, read/write) handle is a file handle obtained from a call to creat, open, dup, dup2, _rtl_creat, or _rtl_open. **Return Value** Upon successful completion, dup returns the new file handle, a nonnegative integer; otherwise, dup returns -1. In the event of error, the global variable... more (see page 895)

dup2 (see page 896)	**Header File** io.h **Category** Input/output Routines **Prototype** `int dup2(int oldhandle, int newhandle);` **Description** Duplicates a file handle (oldhandle) onto an existing file handle (newhandle). • dup2 creates a new file handle that has the following in common with the original file handle: • Same open file or device • Same file pointer (that is, changing the file pointer of one changes the other) • Same access mode (read, write, read/write) dup2 creates a new handle with the value of newhandle. If the file associated with newhandle is open when dup2 is called, the file is closed. newhandle and oldhandle are file handles obtained from... more (see page 896)
eof (see page 898)	**Header File** io.h **Category** Input/output Routines **Prototype** `int eof(int handle);` **Description** Checks for end-of-file. eof determines whether the file associated with handle has reached end-of-file. **Return Value** If the current position is end-of-file, eof returns the value 1; otherwise, it returns 0. A return value of -1 indicates an error; the global variable errno is set to
filelength (see page 899)	**Header File** io.h **Category** Input/output Routines **Prototype** `long filelength(int handle);` **Description** Gets file size in bytes. filelength returns the length (in bytes) of the file associated with handle. **Return Value** On success filelength returns a **long** value the file length in bytes. On error it returns -1 and the global variable errno is set to

getftime, setftime (see page 899)	**Header File**
	io.h
	Category
	Input/output Routines
	Prototype
	`int getftime(int handle, struct ftime *ftimep);`
	`int setftime(int handle, struct ftime *ftimep);`
	Description
	Gets and sets the file date and time.
	getftime retrieves the file time and date for the disk file associated with the open handle. The ftime structure pointed to by ftimep is filled in with the file's time and date.
	setftime sets the file date and time of the disk file associated with the open handle to the date and time in the ftime structure pointed to by ftimep. The file must not be written to after the setftime call... more (see page 899)

isatty (see page 901)	**Header File** io.h **Category** Input/output Routines **Prototype** `int isatty(int handle);` **Description** Checks for device type. isatty determines whether handle is associated with any one of the following character devices: • a terminal • a console • a printer • a serial port **Return Value** If the device is one of the four character devices listed above, isatty returns a nonzero integer. If it is not such a device, isatty returns 0. **Example**
lock (see page 902)	**Header File** io.h **Category** Input/output Routines **Prototype** `int lock(int handle, long offset, long length);` **Description** Sets file-sharing locks. lock provides an interface to the operating system file-sharing mechanism. A lock can be placed on arbitrary, nonoverlapping regions of any file. A program attempting to read or write into a locked region will retry the operation three times. If all three retries fail, the call fails with an error. **Return Value** lock returns 0 on success. On error, lock returns -1 and sets the global variable errno to
locking (see page 903)	**Header File** io.h, sys\locking.h **Category** Input/output Routines **Prototype** `int locking(int handle, int cmd, long length);` **Description** Sets or resets file-sharing locks. locking provides an interface to the operating system file-sharing mechanism. The file to be locked or unlocked is the open file specified by handle. The region to be locked or unlocked starts at the current file position, and is length bytes long. Locks can be placed on arbitrary, nonoverlapping regions of any file. A program attempting to read or write into a locked region will retry the operation three times. If all three retries fail, the call fails with... more (see page 903)
lseek (see page 904)	**Header File** io.h **Category** Input/output Routines **Prototype** `long lseek(int handle, long offset, int fromwhere);` **Description** Moves file pointer. lseek sets the file pointer associated with handle to a new position offset bytes beyond the file location given by fromwhere. fromwhere must be one of the following symbolic constants (defined in io.h):

read (see page 905)	**Header File** io.h **Category** Input/output Routines **Prototype** `int read(int handle, void *buf, unsigned len);` **Description** Reads from file. read attempts to read len bytes from the file associated with handle into the buffer pointed to by buf. For a file opened in text mode, read removes carriage returns and reports end-of-file when it reaches a Ctrl-Z. The file handle handle is obtained from a creat, open, dup, or dup2 call. On disk files, read begins reading at the current file pointer. When the reading is complete, it increments the file pointer by the number of bytes read. On devices, the... more (see page 905)
setmode (see page 906)	**Header File** io.h **Category** Input/output Routines **Prototype** `int setmode(int handle, int amode);` **Description** Sets mode of an open file. setmode sets the mode of the open file associated with handle to either binary or text. The argument amode must have a value of either O_BINARY or O_TEXT, never both. (These symbolic constants are defined in fcntl.h.) **Return Value** setmode returns the previous translation mode if successful. On error it returns -1 and sets the global variable errno to
tell (see page 907)	**Header File** io.h **Category** Input/output Routines **Prototype** `long tell(int handle);` **Description** Gets the current position of a file pointer. tell gets the current position of the file pointer associated with handle and expresses it as the number of bytes from the beginning of the file. **Return Value** tell returns the current file pointer position. A return of -1 (**long**) indicates an error, and the global variable errno is set to
umask (see page 908)	**Header File** io.h, sys\stat.h **Category** Input/output Routines **Prototype** `unsigned umask(unsigned mode);` **Description** Sets file read/write permission mask. The umask function sets the access permission mask used by open and creat. Bits that are set in mode will be cleared in the access permission of files subsequently created by open and creat. The mode can have one of the following values, defined in sys\stat.h:

unlock (see page 909)	**Header File** io.h **Category** Input/output Routines **Prototype** `int unlock(int handle, long offset, long length);` **Description** Releases file-sharing locks. unlock provides an interface to the operating system file-sharing mechanism. unlock removes a lock previously placed with a call to lock. To avoid error, all locks must be removed before a file is closed. A program must release all locks before completing. **Return Value** On success, unlock returns 0 O error, it returns -1. **Example**
vsscanf (see page 910)	**Header File** io.h **Category** Memory and String Manipulation Routines **Prototype** `int vsscanf(const char *buffer, const char *format, va_list arglist);` **Description** Scans and formats input from a stream. The v...scanf functions are known as alternate entry points for the ...scanf functions. They behave exactly like their ...scanf counterparts, but they accept a pointer to a list of arguments instead of an argument list. **Note:** For details on format specifiers, see Scanf Format Specifiers. vsscanf scans a series of input fields, one character at a time, reading from a stream. Then each field is formatted according to a format specifier passed to... more (see page 910)
write (see page 911)	**Header File** io.h **Category** Input/output Routines **Prototype** `int write(int handle, void *buf, unsigned len);` **Description** Writes to a file. write writes a buffer of data to the file or device named by the given handle. handle is a file handle obtained from a creat, open, dup, or dup2 call. This function attempts to write len bytes from the buffer pointed to by buf to the file associated with handle. Except when write is used to write to a text file, the number of bytes written to the file will be no more than the number requested. The maximum number of... more (see page 911)

3.1.4.15.1 _findclose

Header File

io.h

Category

Directory Control Routines

Prototype

```
int _findclose(long handle);
```

Description

Closes the specified search handle and releases associated resources associated with previous calls to findfirst/findnext. The handle parameter is the search handle returned by the previous call to _findfirst.

This function is provided for Microsoft compatibility.

Return Value

On success, returns 0.

Otherwise, returns –1 and sets errno to:

ENOENTFile specification that could not be matched

Portability

	POSIX	Win32	ANSI C	ANSI C++
_findclose		+		

See Also

_findfirst (see page 874)

_findnext (see page 875)

3.1.4.15.2 _findfirst, __wfindfirst

Header File

io.h, wchar.h

Category

Directory Control Routines

Prototype

```
long _findfirst(char *filter, struct _finddata_t *fileinfo);
long __wfindfirst(wchar_t *filter, struct _wfinddata_t *fileinfo);
```

Description

Begins a search of a disk directory to find information about the first instance of a filename that matches a specified filter. The filter parameter is a string that specifies which files to return. Wildcards may be used in the filter. The fileinfo parameter is the file information buffer. If a matching file is found, the fileinfo structure is filled with the file-directory information.

These functions are provided for Microsoft compatibility.

Return Value

On success, returns a unique search handle to a file or group of files matching the filter specification.

Otherwise, returns –1 and sets errno to one of the following values:

ENOENTPath or file name not found

EINVALInvalid filename specification

Portability

	POSIX	Win32	ANSI C	ANSI C++
_findfirst		+		
__wfindfirst		NT only		

See Also

_findclose (see page 873)

_findnext (see page 875)

3.1.4.15.3 _findfirsti64, _wfindfirsti64

Header File

io.h, wchar.h

Category

Directory Control Routines

Prototype

```
long _findfirsti64(char *filter, struct _finddatai64_t *fileinfo);
long _wfindfirsti64(wchar_t *filter, struct _wfinddatai64_t *fileinfo);
```

Description

Begins a search of a disk directory to find information about the first instance of a filename that matches a specified filter. The filter parameter is a string that specifies which files to return. Wildcards may be used in the filter. The fileinfo parameter is the file information buffer. If a matching file is found, the fileinfo structure is filled with the file-directory information.

These i64 versions are for 64 bit filesize use and are provided for Microsoft compatibility.

Return Value

On success, returns a unique search handle identifying the file or group of files matching the filter specification.

Otherwise, returns –1 and sets errno to one of the following values:

ENOENTFile specification that could not be matched

EINVALInvalid filename specification

Portability

	POSIX	Win32	ANSI C	ANSI C++
_findfirsti64		+		
_wfindfirsti64		NT only		

3.1.4.15.4 _findnext, __wfindnext

Header File

io.h, wchar.h

Category

Directory Control Routines

Prototype

```
long _findnext(long handle, struct _finddata_t *fileinfo);
long __wfindnext(long handle, struct _wfinddata_t *fileinfo);
```

Description

Finds subsequent files, if any, that match the filter argument in a previous call to _findfirst/__wfindfirst. Then, _findnext/__wfindnext updates the fileinfo structure with the necessary information for continuing the search. One file name for each call to _tfindnext is returned until no more files are found in the directory matching the pathname (filter).

The handle parameter is the search handle returned by a previous call to _findfirst. The fileinfo parameter is the file information buffer.

These functions are provided for Microsoft compatibility.

Return Value

On success, returns 0.

Otherwise, returns –1 and sets errno to:

ENOENTFile specification that could not be matched

Portability

	POSIX	Win32	ANSI C	ANSI C++
_findnext		+		
__wfindnext		NT only		

See Also

_findclose (see page 873)

_findfirst (see page 874)

3.1.4.15.5 _findnexti64, _wfindnexti64

Header File

io.h, wchar.h

Category

Directory Control Routines

Prototype

```
long _findnexti64(long handle, struct _finddatai64_t *fileinfo);
__int64 _wfindnexti64(long handle, struct _wfinddata_t *fileinfo);
```

Description

Finds subsequent files, if any, that match the filter argument in a previous call to _findfirsti64/_wfindfirsti64. Then, _findnexti64/_wfindnexti64 updates the fileinfo structure with the necessary information for continuing the search. One file name for each call to _tfindnext is returned until no more files are found in the directory matching the pathname (filter).

The handle parameter is the search handle returned by a previous call to _findfirst. The fileinfo parameter is the file information buffer.

These i64 versions are for 64 bit filesize use and are provided for Microsoft compatibility.

Return Value

On success, returns 0.

Otherwise, returns –1 and sets errno to:

ENOENTFile specification that could not be matched

Portability

	POSIX	Win32	ANSI C	ANSI C++
_findnexti64		+		
_wfindnexti64		NT only		

3.1.4.15.6 _get_osfhandle

Header File

io.h

Category

Input/output Routines

Prototype

```
long _get_osfhandle(int filehandle);
```

Description

Associates file handles.

The _get_osfhandle function associates an operating system file handle with an existing runtime file handle. The variable filehandle is the file handle of your program.

Return value

On success, _get_osfhandle returns an operating system file handle corresponding to the variable filehandle.

On error, the function returns -1 and sets the global variable errno to

EBADF	an invalid file handle

Example

```
#include <windows.h>
#include <fcntl.h>
#include <stdio.h>
#include <io.h>
//Example for _get_osfhandle() and _open_osfhandle()
BOOL InitApplication(HINSTANCE hInstance);
HWND InitInstance(HINSTANCE hInstance, int nCmdShow);
LRESULT FAR PASCAL _export MainWndProc(HWND hWnd, UINT message,
            WPARAM wParam, LPARAM lParam);
Example_get_osfhandle(HWND hWnd);
#pragma argsused
int PASCAL WinMain(HINSTANCE hInstance, HINSTANCE hPrevInstance,
        LPSTR lpCmdLine, int nCmdShow)
{
MSG msg;      // message
  if (!InitApplication(hInstance))  // Initialize shared things
   return (FALSE); // Exits if unable to initialize
  /* Perform initializations that apply to a specific instance */
  if (!(InitInstance(hInstance, nCmdShow)))
   return (FALSE);
  /* Acquire and dispatch messages until a WM_QUIT message is received. */
```

```
    while (GetMessage(&msg, // message structure
     NULL, // handle of window receiving the message
     NULL, // lowest message to examine
     NULL))  // highest message to examine
    {
    TranslateMessage(&msg); // Translates virtual key codes
    DispatchMessage(&msg);  // Dispatches message to window
    }
    return (msg.wParam);  // Returns the value from PostQuitMessage
  }
  BOOL InitApplication(HINSTANCE hInstance)

3.1.4.15.7 _open_osfhandle

Header File

io.h

Category

Input/output Routines

Prototype

```
int _open_osfhandle(long osfhandle, int flags);
```

Description

Associates file handles.

The _open_osfhandle function allocates a runtime file handle and sets it to point to the operating system file handle specified by osfhandle.

The value flags is a bitwise OR combination of one or more of the following manifest constants (defined in fcntl.h):

O_APPEND	Repositions the file pointer to the end of the file before every write operation.
O_RDONLY	Opens the file for reading only.
O_TEXT	Opens the file in text (translated) mode.

Return Value

On success, _open_osfhandle returns a C runtime file handle. Otherwise, it returns -1.

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.15.8 _rtl_chmod, _wrtl_chmod

Header File

io.h

Category

Input/output Routines

Prototype

```
int _rtl_chmod(const char *path, int func [, int attrib]);
int _wrtl_chmod(const wchar_t *path, int func, ... );
```

Description

Gets or sets file attributes.

Note: The _rtl_chmod function replaces _chmod

which is obsolete_rtl_chmod can either fetch or set file attributes. If func is 0, _rtl_chmod returns the current attributes for the file. If func is 1, the attribute is set to attrib.

attrib can be one of the following symbolic constants (defined in dos.h):

FA_RDONLY	Read-only attribute
FA_HIDDEN	Hidden file
FA_SYSTEM	System file
FA_LABEL	Volume label
FA_DIREC	Directory
FA_ARCH	Archive

Return Value

On success, _rtl_chmod returns the file attribute word.

On error, it returns a value of -1 and sets the global variable errno to one of the following values:

ENOENT	Path or filename not found
EACCES	Permission denied

Example

```
#include <errno.h>
#include <stdio.h>
#include <dir.h>
#include <io.h>
```

```
int get_file_attrib(char *filename);
int main(void)
{
  char filename[128];
  int attrib;
  printf("Enter a filename:");
  scanf("%s", filename);
  attrib = get_file_attrib(filename);
  if (attrib == -1)
     switch(errno)
     {
        case ENOENT : printf("Path or file not found.\n");
                      break;
        case EACCES : printf("Permission denied.\n");
                      break;
        default:      printf("Error number: %d", errno);
                      break;
     }
  else
     {
        if (attrib & FA_RDONLY)
           printf("%s is read-only.\n", filename);
        if (attrib & FA_HIDDEN)
           printf("%s is hidden.\n", filename);
        if (attrib & FA_SYSTEM)
           printf("%s is a system file.\n", filename);
        if (attrib & FA_DIREC)
           printf("%s is a directory.\n", filename);
        if (attrib & FA_ARCH)
           printf("%s is an archive file.\n", filename);
     }
  return 0;
}
/* returns the attributes of a DOS file */
int get_file_attrib(char *filename)
{
   return(_rtl_chmod(filename, 0));
}
```

Portability

_rtl_chmod		+		
_wrtl_chmod		NT only		

3.1.4.15.9 _rtl_close

Header File

io.h

Category

Input/output Routines

Prototype

```
int _rtl_close(int handle);
```

Description

Closes a file.

Note: This function replaces _close which is obsolete

The _rtl_close function closes the file associated with handle, a file handle obtained from a call to creat, creatnew, creattemp, dup, dup2, open, _rtl_creat, or _rtl_open.

It does not write a Ctrl-Z character at the end of the file. If you want to terminate the file with a Ctrl-Z, you must explicitly output one.

Return Value

On success, _rtl_close returns 0.

On error (if it fails because handle is not the handle of a valid, open file), _rtl_close returns a value of -1 and the global variable errno is set to

EBADF	Bad file number

Example

```
#include <string.h>
#include <stdio.h>
#include <fcntl.h>
#include <io.h>
int main(void)
{
   int handle;
   char msg[] = "Hello world";
   if ((handle = _rtl_open("TEST.$$$", O_RDWR)) == -1)
   {
      perror("Error:");
      return 1;
   }
   _rtl_write(handle, msg, strlen(msg));
   _rtl_close(handle);
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.15.10 _rtl_creat, _wrtl_creat

Header File

io.h

Category

Input/output Routines

Prototype

```
int _rtl_creat(const char *path, int attrib);
```

```
int _wrtl_creat(const wchar_t *path, int attrib);
```

Description

Creates a new file or overwrites an existing one.

Note: The _rtl_creat function replaces _creat,

which is obsolete_rtl_creat opens the file specified by path. The file is always opened in binary mode. Upon successful file creation, the file pointer is set to the beginning of the file. The file is opened for both reading and writing.

If the file already exists its size is reset to 0. (This is essentially the same as deleting the file and creating a new file with the same name.)

The attrib argument is an OR'ed combination of one or more of the following constants (defined in dos.h):

FA_RDONLY	Read-only attribute
FA_HIDDEN	Hidden file
FA_SYSTEM	System file

Return Value

On success, _rtl_creat returns the new file handle (a non-negative integer).

On error, it returns -1 and sets the global variable errno to one of the following values:

EACCESPermission denied

EMFILEToo many open files

ENOENTPath or file name not found

Example

```
#include <string.h>
#include <stdio.h>
#include <io.h>
int main() {
  unsigned count;
  int handle;
  char buf[11] = "0123456789";
  /* Create a 10-byte file using _rtl_creat. */
  if ((handle = _rtl_creat("DUMMY2.FIL", 0)) < 0) {
    perror("Unable to _rtl_create DUMMY2.FIL");
    return 1;
  }
  if (_rtl_write(handle, buf, strlen(buf)) < 0) {
    perror("Unable to _rtl_write to DUMMY2.FIL");
    return 1;
  }
  _rtl_close(handle);
  return 0;
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
_rtl_crea		+		
_wrtl_creat		NT only		

3.1.4.15.11 _rtl_open, _wrtl_open

Header File

io.h

Category

Input/output Routines

Prototype

```
int _rtl_open(const char *filename, int oflags);
```

```
int _wrtl_open(const wchar_t *path, int oflags);
```

Description

Opens a file for reading or writing.

Note: The _rtl_open function replaces _open which is obsolete.

_rtl_open opens the file specified by filename, then prepares it for reading or writing, as determined by the value of oflags. The file is always opened in binary mode.

oflags uses the flags from the following two lists. Only one flag from List 1 can be used (and one must be used) and the flags in List 2 can be used in any logical combination.

O_RDONLY	Open for reading.
O_WRONLY	Open for writing.
O_RDWR	Open for reading and writing.

The following additional values can be included in oflags (using an OR operation):

O_NOINHERIT	The file is not passed to child programs.
SH_COMPAT	Allow other opens with SH_COMPAT. All other openings of a file with the SH_COMPAT flag must be opened using SH_COMPAT flag. You can request a file open that uses SH_COMPAT logically OR'ed with some other flag (for example, SH_COMPAT | SH_DENWR is allowed). The call will fail if the file has already been opened in any other shared mode.
SH_DENYRW	Only the current handle can have access to the file.
SH_DENWR	Allow only reads from any other open to the file.
SH_DENYRD	Allow only writes from any other open to the file.
SH_DENYNO	Allow other shared opens to the file, but not other SH_COMPAT opens.

Note: These symbolic constants are defined in fcntl.h and share.h.

Only one of the SH_DENYxx values can be included in a single _rtl_open routine. These file-sharing attributes are in addition to any locking performed on the files.

The maximum number of simultaneously open files is defined by HANDLE_MAX.

Return Value

On success:_rtl_open returns a non-negative integer (the file handle). The file pointer, which marks the current position in the file, is set to the beginning of the file.

On error, it returns -1 and sets the global variable errno to one of the following values:

EACCES	Permission denied
EINVACC	Invalid access code
EMFILE	Too many open files
ENOENT	Path or file not found

Example

```
#include <string.h>
#include <stdio.h>
```

```
#include <fcntl.h>
#include <io.h>
int main(void)
{
   int handle;
   char msg[] = "Hello world";
   if ((handle = _rtl_open("TEST.$$$", O_RDWR)) == -1)
   {
      perror("Error:");
      return 1;
   }
   _rtl_write(handle, msg, strlen(msg));
   _rtl_close(handle);
   return 0;
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
_rtl_open		+		
_wrtl_open		NT only		

3.1.4.15.12 _rtl_read

Header File

io.h

Category

Input/output Routines

Prototype

```
int _rtl_read(int handle, void *buf, unsigned len);
```

Description

Reads from file.

Note: This function replaces _read which is obsolete.

This function reads len bytes from the file associated with handle into the buffer pointed to by buf. When a file is opened in text mode, _rtl_read does not remove carriage returns.

The argument handle is a file handle obtained from a creat, open, dup, or dup2 call.

On disk files, _rtl_read begins reading at the current file pointer. When the reading is complete, it increments the file pointer by the number of bytes read. On devices, the bytes are read directly from the device.

The maximum number of bytes it can read is UINT_MAX -1 (because UINT_MAX is the same as -1, the error return indicator). UINT_MAX is defined in limits.h.

Return Value

On success, _rtl_read returns either

- a positive integer, indicating the number of bytes placed in the buffer
- zero, indicating end-of-file

On error, it returns -1 and sets the global variable errno to one of the following values:

EACCES	Permission denied
EBADF	Bad file number

Example

```
#include <stdio.h>
#include <io.h>
#include <alloc.h>
#include <fcntl.h>
#include <process.h>
#include <sys\stat.h>
int main(void)
{
   void *buf;
   int handle, bytes;
   buf = malloc(10);
/*
Looks for a file in the current directory named TEST.$$$ and attempts to read 10 bytes from
it. To use this example you should create the file TEST.$$$
 */
   if ((handle =
       open("TEST.$$$", O_RDONLY | O_BINARY, S_IWRITE | S_IREAD)) == -1)
   {
      printf("Error Opening File\n");
      exit(1);
   }
   if ((bytes = _rtl_read(handle, buf, 10)) == -1) {
      printf("Read Failed.\n");
      exit(1);
   }
   else {
      printf("_rtl_read: %d bytes read.\n", bytes);
   }
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.15.13 _rtl_write

Header File

io.h

Category

Input/output Routines

Prototype

```
int _rtl_write(int handle, void *buf, unsigned len);
```

Description

Writes to a file.

Note: This function replaces _write which is obsolete.

_rtl_write attempts to write len bytes from the buffer pointed to by buf to the file associated with handle.

The maximum number of bytes that _rtl_write can write is UINT_MAX -1 (because UINT_MAX is the same as -1), which is the error return indicator for _rtl_write. UINT_MAX is defined in limits.h. _rtl_write does not translate a linefeed character (LF) to a CR/LF pair because all its files are binary files.

If the number of bytes actually written is less than that requested the condition should be considered an error and probably indicates a full disk.

For disk files, writing always proceeds from the current file pointer. On devices, bytes are directly sent to the device.

For files opened with the O_APPEND option, the file pointer is not positioned to EOF before writing the data.

Return Value

On success, _rtl_write returns number of bytes written.

On error, it returns -1 and sets the global variable errno to one of the following values:

EACCES	Permission denied
EBADF	Bad file number

Example

```
#include <stdio.h>
#include <io.h>
#include <alloc.h>
#include <fcntl.h>
#include <process.h>
#include <sys\stat.h>
int main(void)
{
   void *buf;
   int handle, bytes;
   buf = malloc(200);
/*
Create a file name TEST.$$$ in the current directory and writes 200 bytes to it. If TEST.$$$
already exists, it's overwritten.
 */
   if ((handle = open("TEST.$$$", O_CREAT | O_WRONLY | O_BINARY,
                      S_IWRITE | S_IREAD)) == -1)
   {
      printf("Error Opening File\n");
      exit(1);
   }
   if ((bytes = _rtl_write(handle, buf, 200)) == -1) {
      printf("Write Failed.\n");
      exit(1);
   }
   printf("_rtl_write: %d bytes written.\n",bytes);
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.15.14 access, _waccess

Header File

io.h

Category

Input/output Routines

Prototype

```
int access(const char *filename, int amode);
```

```
int _waccess(const wchar_t *filename, int amode);
```

Description

Determines accessibility of a file.

access checks the file named by filename to determine if it exists, and whether it can be read, written to, or executed.

The list of amode values is as follows:

06	Check for read and write permission
04	Check for read permission
02	Check for write permission
01	Execute (ignored)
00	Check for existence of file

All existing files have read access (amode equals 04), so 00 and 04 give the same result. Similarly, amode values of 06 and 02 are equivalent because under Win32 write access implies read access.

If filename refers to a directory, access simply determines whether the directory exists.

Return Value

If the requested access is allowed, access returns 0; otherwise, it returns a value of -1, and the global variable errno is set to one of the following values:

ENOENT	Path or file name not found
EACCES	Permission denied

Example

```
 #include <stdio.h>
 #include <io.h>
 int file_exists(char *filename);
 int main(void)
 {
printf("Does NOTEXIST.FIL exist: %s\n",
 file_exists("NOTEXISTS.FIL") ? "YES" : "NO");
return 0;
 }
 int file_exists(char *filename)
 {
   return (access(filename, 0) == 0);
 }
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
access	+	+		
_waccess		NT only		

3.1.4.15.15 chmod, _wchmod

Header File

io.h

Category

Input/output Routines

Prototype

```
int chmod(const char *path, int amode);
int _wchmod(const wchar_t *path, int amode);
```

Description

Changes file access mode.

chmod sets the file-access permissions of the file given by path according to the mask given by amode. path points to a string.

amode can contain one or both of the symbolic constants S_IWRITE and S_IREAD (defined in sys\stat.h).

S_IWRITE	Permission to write
S_IREAD	Permission to read
S_IREAD | S_IWRITE	Permission to read and write (write permission implies read permission)

Return Value

Upon successfully changing the file access mode, chmod returns 0. Otherwise, chmod returns a value of -1.

In the event of an error, the global variable errno is set to one of the following values:

EACCES	Permission denied
ENOENT	Path or file name not found

Example

```
#include <errno.h>
#include <stdio.h>
#include <io.h>
#include <process.h>
#include <sys\stat.h>
void main(void)
{
  char filename[64];
  struct stat stbuf;
  int amode;
  printf("Enter name of file: ");
  scanf("%s", filename);
  if (stat(filename, &stbuf) != 0)
  {
    perror("Unable to get file information");
    exit(1);
  }
  if (stbuf.st_mode & S_IWRITE)
  {
    printf("Changing to read-only\n");
    amode = S_IREAD;
  }
  else
```

```
  {
    printf("Changing to read-write\n");
    amode = S_IREAD|S_IWRITE;
  }
  if (chmod(filename, amode) != 0)
  {
    perror("Unable to change file mode");
    exit(1);
  }
  exit(0);
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
chmod	+	+		
_wchmod		NT only		

3.1.4.15.16 chsize

Header File

io.h

Category

Input/output Routines

Prototype

```
int chsize(int handle, long size);
```

Description

Changes the file size.

chsize changes the size of the file associated with handle. It can truncate or extend the file, depending on the value of size compared to the file's original size.

The mode in which you open the file must allow writing.

If chsize extends the file, it will append null characters (\0). If it truncates the file, all data beyond the new end-of-file indicator is lost.

Return Value

On success, chsize returns 0. On failure, it returns -1 and the global variable errno is set to one of the following values:

EACCES	Permission denied
EBADF	Bad file number
ENOSPC	No space left on device

Example

```
#include <string.h>
#include <fcntl.h>
#include <io.h>
int main(void)
{
   int handle;
   char buf[11] = "0123456789";
```

```
    /* create text file containing 10 bytes */
    handle = open("DUMMY.FIL", O_CREAT);
    write(handle, buf, strlen(buf));
    /* truncate the file to 5 bytes in size */
    chsize(handle, 5);
    /* close the file */
    close(handle);
    return 0;
}
```

Portability

3.1.4.15.17 close

Header File

io.h

Category

Input/output Routines

Prototype

```
int close(int handle);
```

Description

Closes a file.

The close function closes the file associated with handle, a file handle obtained from a call to creat, creatnew, creattemp, dup, dup2, open, _rtl_creat, or _rtl_open.

It does not write a Ctrl-Z character at the end of the file. If you want to terminate the file with a Ctrl-Z, you must explicitly output one.

Return Value

Upon successful completion, close returns 0.

On error (if it fails because handle is not the handle of a valid, open file), close returns a value of -1 and the global variable errno is set to

EBADF	Bad file number

Example

```
#include <string.h>
#include <stdio.h>
#include <fcntl.h>
#include <io.h>
main()
{
  int handle;
  char buf[11] = "0123456789";
  /* create a file containing 10 bytes */
  handle = open("NEW.FIL", O_CREAT);
  if (handle > -1)
  {
    write(handle, buf, strlen(buf));
```

```
    close(handle);                    /* close the file */
  }
  else
  {
    printf("Error opening file\n");
  }
  return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
+	+		

3.1.4.15.18 _creat, _wcreat

Header File

io.h

Category

Input/output Routines

Prototype

```
int creat(const char *path, int amode);
```

```
int _wcreat(const wchar_t *path, int amode);
```

Description

Creates a new file or overwrites an existing one.

Note: Remember that a backslash in a path requires '\\'.

creat creates a new file or prepares to rewrite an existing file given by path. amode applies only to newly created files.

A file created with creat is always created in the translation mode specified by the global variable _fmode (O_TEXT or O_BINARY).

If the file exists and the write attribute is set, creat truncates the file to a length of 0 bytes, leaving the file attributes unchanged. If the existing file has the read-only attribute set, the creat call fails and the file remains unchanged.

The creat call examines only the S_IWRITE bit of the access-mode word amode. If that bit is 1, the file can be written to. If the bit is 0, the file is marked as read-only. All other operating system attributes are set to 0.

amode can be one of the following (defined in sys\stat.h):

S_IWRITE	Permission to write
S_IREAD	Permission to read
S_IREAD / S_IWRITE	Permission to read and write (write permission implies read permission)

Return Value

Upon successful completion, _creat returns the new file handle, a nonnegative integer; otherwise, it returns -1.

In the event of error, the global variable errno is set to one of the following:

EACCES	Permission denied
ENOENT	Path or file name not found
EMFILE	Too many open files

Example

```
#include <sys\stat.h>
#include <string.h>
#include <fcntl.h>
#include <io.h>
int main(void)
{
   int handle;
   char buf[11] = "0123456789";
   /* change the default file mode from text to binary */
   _fmode = O_BINARY;
   /* create a binary file for reading and writing */
   handle = creat("DUMMY.FIL", S_IREAD |S_IWRITE);
   /* write 10 bytes to the file */
   write(handle, buf, strlen(buf));
   /* close the file */
   close(handle);
   return 0;
}
```

Portability

	POSIX	Win32	ANSI C	ANSI C++
creat	+	+		
_wcreat		NT only		

3.1.4.15.19 creatnew

Header File

io.h

Category

Input/output Routines

Prototype

```
int creatnew(const char *path, int mode);
```

Description

Creates a new file.

creatnew is identical to _rtl_creat with one exception: If the file exists, creatnew returns an error and leaves the file untouched.

The mode argument to creatnew can be zero or an OR-combination of any one of the following constants (defined in dos.h):

FA_HIDDEN	Hidden file
FA_RDONLY	Read-only attribute
FA_SYSTEM	System file

Return Value

Upon successful completion, creatnew returns the new file handle, a nonnegative integer; otherwise, it returns -1.

In the event of error, the global variable errno is set to one of the following values:

EACCES	Permission denied
EEXIST	File already exists
EMFILE	Too many open files
ENOENT	Path or file name not found

Example

```
#include <string.h>
#include <stdio.h>
#include <errno.h>
#include <io.h>
int main(void)
{
   int handle;
   char buf[11] = "0123456789";
   /* attempt to create a file that doesn't already exist */
   handle = creatnew("DUMMY.FIL", 0);
if (handle == -1)
      printf("DUMMY.FIL already exists.\n");
   else
   {
      printf("DUMMY.FIL successfully created.\n");
      write(handle, buf, strlen(buf));
      close(handle);
   }
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.15.20 creattemp

Header File

io.h

Category

Input/output Routines

Prototype

```
int creattemp(char *path, int attrib);
```

Description

Creates a unique file in the directory associated with the path name.

A file created with creattemp is always created in the translation mode specified by the global variable _fmode (O_TEXT or O_BINARY).

path is a path name ending with a backslash (\). A unique file name is selected in the directory given by path. The newly created file name is stored in the path string supplied. path should be long enough to hold the resulting file name. The file is not

automatically deleted when the program terminates.

The attrib argument to creattemp can be zero or an OR-combination of any one of the following constants (defined in dos.h):

FA_HIDDEN	Hidden file
FA_RDONLY	Read-only attribute
FA_SYSTEM	System file

Upon successful file creation, the file pointer is set to the beginning of the file. The file is opened for both reading and writing.

Return Value

Upon successful completion, the new file handle, a nonnegative integer, is returned; otherwise, -1 is returned.

In the event of error, the global variable errno is set to one of the following values:

EACCES	Permission denied
EMFILE	Too many open files
ENOENT	Path or file name not found

Example

```
#include <string.h>
#include <stdio.h>
#include <io.h>
int main(void)
{
   int handle;
   char pathname[128];
   strcpy(pathname, "\\");
   /* create a unique file in the root directory */
   handle = creattemp(pathname, 0);
   printf("%s was the unique file created.\n", pathname);
   close(handle);
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.15.21 dup

Header File

io.h

Category

Input/output Routines

Prototype

```
int dup(int handle);
```

Description

Duplicates a file handle.

- dup creates a new file handle that has the following in common with the original file handle:
- Same open file or device
- Same file pointer (that is, changing the file pointer of one changes the other)
- Same access mode (read, write, read/write)

handle is a file handle obtained from a call to creat, open, dup, dup2, _rtl_creat, or _rtl_open.

Return Value

Upon successful completion, dup returns the new file handle, a nonnegative integer; otherwise, dup returns -1.

In the event of error, the global variable errno is set to one of the following values:

EBADF	Bad file number
EMFILE	Too many open files

Example

```
#include <string.h>
#include <stdio.h>
#include <io.h>
void flush(FILE *stream);
int main(void)
{
  FILE *fp;
  char msg[] = "This is a test";
  /* create a file */
  fp = fopen("DUMMY.FIL", "w");
  /* write some data to the file */
  fwrite(msg, strlen(msg), 1, fp);
  printf("Press ENTER to flush DUMMY.FIL:");
  getchar();
  /* flush the data to DUMMY.FIL without closing it */
  flush(fp);
  printf("\nFile was flushed, Press ENTER to quit:");
  getchar();
  return 0;
}
void flush(FILE *stream)
{
  int duphandle;
  /* flush TC's internal buffer */
  fflush(stream);
  /* make a duplicate file handle */
  duphandle = dup(fileno(stream));
  /* close the duplicate handle to flush the DOS buffer */
  close(duphandle);
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
+	+		

3.1.4.15.22 dup2

Header File

io.h

Category

Input/output Routines

Prototype

```
int dup2(int oldhandle, int newhandle);
```

Description

Duplicates a file handle (oldhandle) onto an existing file handle (newhandle).

- dup2 creates a new file handle that has the following in common with the original file handle:
- Same open file or device
- Same file pointer (that is, changing the file pointer of one changes the other)
- Same access mode (read, write, read/write)

dup2 creates a new handle with the value of newhandle. If the file associated with newhandle is open when dup2 is called, the file is closed.

newhandle and oldhandle are file handles obtained from a creat, open, dup, or dup2 call.

Return Value

dup2 returns 0 on successful completion, -1 otherwise.

In the event of error, the global variable errno is set to one of the following values:

EBADF Bad file number

EMFILE Too many open files

Example

```
#include <sys\stat.h>
#include <string.h>
#include <fcntl.h>
#include <io.h>
#define STDOUT 1
int main(void)
{
   int nul, oldstdout;
   char msg[] = "This is a test";
   /* create a file */
   nul = open("DUMMY.FIL", O_CREAT | O_RDWR,
      S_IREAD | S_IWRITE);
   /* create a duplicate handle for standard output */
   oldstdout = dup(STDOUT);
   /*
      redirect standard output to DUMMY.FIL
      by duplicating the file handle onto
      the file handle for standard output.
   */
   dup2(nul, STDOUT);
   /* close the handle for DUMMY.FIL */
   close(nul);
   /* will be redirected into DUMMY.FIL */
   write(STDOUT, msg, strlen(msg));
   /* restore original standard output handle */
   dup2(oldstdout, STDOUT);
   /* close duplicate handle for STDOUT */
   close(oldstdout);
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
+	+		

3.1.4.15.23 eof

Header File

io.h

Category

Input/output Routines

Prototype

```
int eof(int handle);
```

Description

Checks for end-of-file.

eof determines whether the file associated with handle has reached end-of-file.

Return Value

If the current position is end-of-file, eof returns the value 1; otherwise, it returns 0. A return value of -1 indicates an error; the global variable errno is set to

EBADF	Bad file number

Example

```
#include <sys\stat.h>
#include <string.h>
#include <stdio.h>
#include <fcntl.h>
#include <io.h>
int main(void)
{
   int handle;
   char msg[] = "This is a test";
   char ch;
   /* create a file */
   handle = open("DUMMY.FIL",
                 O_CREAT | O_RDWR,
                 S_IREAD | S_IWRITE);
   /* write some data to the file */
   write(handle, msg, strlen(msg));
   /* seek to the beginning of the file */
   lseek(handle, 0L, SEEK_SET);
   /* reads chars from the file until it reaches EOF */
   do
   {
      read(handle, &ch, 1);
      printf("%c", ch);
   } while (!eof(handle));
   close(handle);
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.15.24 filelength

Header File

io.h

Category

Input/output Routines

Prototype

```
long filelength(int handle);
```

Description

Gets file size in bytes.

filelength returns the length (in bytes) of the file associated with handle.

Return Value

On success filelength returns a **long** value the file length in bytes. On error it returns -1 and the global variable errno is set to

EBADF	Bad file number

Example

```
#include <string.h>
#include <stdio.h>
#include <fcntl.h>
#include <io.h>
int main(void)
{
   int handle;
   char buf[11] = "0123456789";
   /* create a file containing 10 bytes */
   handle = open("DUMMY.FIL", O_CREAT);
   write(handle, buf, strlen(buf));
   /* display the size of the file */
   printf("file length in bytes: %ld\n", filelength(handle));
   /* close the file */
   close(handle);
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.15.25 getftime, setftime

Header File

io.h

Category

Input/output Routines

Prototype

```
int getftime(int handle, struct ftime *ftimep);
int setftime(int handle, struct ftime *ftimep);
```

Description

Gets and sets the file date and time.

getftime retrieves the file time and date for the disk file associated with the open handle. The ftime structure pointed to by ftimep is filled in with the file's time and date.

setftime sets the file date and time of the disk file associated with the open handle to the date and time in the ftime structure pointed to by ftimep. The file must not be written to after the setftime call or the changed information will be lost. The file must be open for writing; an EACCES error will occur if the file is open for read-only access.

setftime requires the file to be open for writing; an EACCES error will occur if the file is open for read-only access.

The ftime structure is defined as follows:

```
struct ftime {
unsigned ft_tsec: 5; /* two seconds */
unsigned ft_min: 6; /* minutes */
unsigned ft_hour: 5; /* hours */
unsigned ft_day: 5; /* days */
unsigned ft_month: 4; /* months */
unsigned ft_year: 7; /* year - 1980*/
};
```

Return Value

getftime and setftime return 0 on success.

In the event of an error return -1 is returned and the global variable errno is set to one of the following values:

EACCES	Permission denied
EBADF	Bad file number
EINVFNC	Invalid function number

Example

```
#include <stdio.h>
#include <io.h>
int main(void)
{
   FILE *stream;
   std::ftime ft;
   if ((stream = fopen("TEST.$$$",
        "wt")) == NULL)
   {
      fprintf(stderr, "Cannot open output file.\n");
      return 1;
   }
   getftime(fileno(stream), &ft);
```

```
    printf("File time: %u:%u:%u\n",
           ft.ft_hour, ft.ft_min,
           ft.ft_tsec * 2);
    printf("File date: %u/%u/%u\n",
           ft.ft_month, ft.ft_day,
           ft.ft_year+1980);
    fclose(stream);
    return 0;
}
```

3.1.4.15.26 isatty

Header File

io.h

Category

Input/output Routines

Prototype

```
int isatty(int handle);
```

Description

Checks for device type.

isatty determines whether handle is associated with any one of the following character devices:

- a terminal
- a console
- a printer
- a serial port

Return Value

If the device is one of the four character devices listed above, isatty returns a nonzero integer. If it is not such a device, isatty returns 0.

Example

```
#include <stdio.h>
#include <io.h>
int main(void)
{
    int handle;
    handle = fileno(stdout);
    if (isatty(handle))
       printf("Handle %d is a device type\n", handle);
    else
       printf("Handle %d isn't a device type\n", handle);
    return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
+	+		

3.1.4.15.27 lock

Header File

io.h

Category

Input/output Routines

Prototype

```
int lock(int handle, long offset, long length);
```

Description

Sets file-sharing locks.

lock provides an interface to the operating system file-sharing mechanism.

A lock can be placed on arbitrary, nonoverlapping regions of any file. A program attempting to read or write into a locked region will retry the operation three times. If all three retries fail, the call fails with an error.

Return Value

lock returns 0 on success. On error, lock returns -1 and sets the global variable errno to

EACCES	Locking violation

Example

```
#include <io.h>
#include <fcntl.h>
#include <sys\stat.h>
#include <process.h>
#include <share.h>
#include <stdio.h>
int main(void)
{
   int handle, status;
   long length;
   handle = _sopen("c:\\autoexec.bat",
      O_RDONLY,SH_DENYNO,S_IREAD);
   if (handle < 0)
   {
      printf("_sopen failed\n");
      exit(1);
   }
   length = filelength(handle);
   status = lock(handle,0L,length/2);
   if (status == 0)
      printf("lock succeeded\n");
   else
      printf("lock failed\n");
   status = unlock(handle,0L,length/2);
   if (status == 0)
      printf("unlock succeeded\n");
   else
      printf("unlock failed\n");
   close(handle);
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.15.28 locking

Header File

io.h, sys\locking.h

Category

Input/output Routines

Prototype

```
int locking(int handle, int cmd, long length);
```

Description

Sets or resets file-sharing locks.

locking provides an interface to the operating system file-sharing mechanism. The file to be locked or unlocked is the open file specified by handle. The region to be locked or unlocked starts at the current file position, and is length bytes long.

Locks can be placed on arbitrary, nonoverlapping regions of any file. A program attempting to read or write into a locked region will retry the operation three times. If all three retries fail, the call fails with an error.

The cmd specifies the action to be taken (the values are defined in sys\locking.h):

LK_LOCK	Lock the region. If the lock is unsuccessful, try once a second for 10 seconds before giving up.
LK_RLCK	Same as LK_LOCK.
LK_NBLCK	Lock the region. If the lock if unsuccessful, give up immediately.
LK_NBRLCK	Same as LK_NBLCK.
LK_UNLCK	Unlock the region, which must have been previously locked.

Return Value

On successful operations, locking returns 0. Otherwise, it returns -1, and the global variable errno is set to one of the following values:

EACCES	File already locked or unlocked
EBADF	Bad file number
EDEADLOCK	File cannot be locked after 10 retries (cmd is LK_LOCK or LK_RLCK)
EINVAL	Invalid cmd, or SHARE.EXE not loaded

Example

```
#include <io.h>
#include <fcntl.h>
#include <process.h>
#include <share.h>
#include <stdio.h>
#include <sys\locking.h>
int main(void)
{
  int handle, status;
```

```
  long length;
  handle = sopen("c:\\autoexec.bat", O_RDONLY,SH_DENYNO);
  if (handle < 0) {
    printf("sopen failed\n");
    exit(1);
  }
  length = filelength(handle);
  status = locking(handle,LK_LOCK,length/2);
  if (status == 0)
    printf("lock succeeded\n");
  else
    perror("lock failed");
  status = locking(handle,LK_UNLCK,length/2);
  if (status == 0)
    printf("unlock succeeded\n");
  else
    perror("unlock failed");
  close(handle);
  return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
	+		

3.1.4.15.29 lseek

Header File

io.h

Category

Input/output Routines

Prototype

```
long lseek(int handle, long offset, int fromwhere);
```

Description

Moves file pointer.

lseek sets the file pointer associated with handle to a new position offset bytes beyond the file location given by fromwhere. fromwhere must be one of the following symbolic constants (defined in io.h):

SEEK_CUR	Current file pointer position
SEEK_END	End-of-file
SEEK_SET	File beginning

Return Value

lseek returns the offset of the pointer's new position measured in bytes from the file beginning. lseek returns -1L on error, and the global variable errno is set to one of the following values:

EBADF	Bad file handle
EINVAL	Invalid argument
ESPIPE	Illegal seek on device

On devices incapable of seeking (such as terminals and printers), the return value is undefined.

Example

```
#include <sys\stat.h>
#include <string.h>
#include <stdio.h>
#include <fcntl.h>
#include <io.h>
int main(void)
{
    int handle;
    char msg[] = "This is a test";
    char ch;
    /* create a file */
    handle = open("TEST.$$$", O_CREAT | O_RDWR, S_IREAD | S_IWRITE);
    /* write some data to the file */
    write(handle, msg, strlen(msg));
    /* seek to the beginning of the file */
    lseek(handle, 0L, SEEK_SET);
    /* reads chars from the file until we hit EOF */
    do
    {
       read(handle, &ch, 1);
       printf("%c", ch);
    }  while (!eof(handle));
    close(handle);
    return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
+	+		

3.1.4.15.30 read

Header File

io.h

Category

Input/output Routines

Prototype

```
int read(int handle, void *buf, unsigned len);
```

Description

Reads from file.

read attempts to read len bytes from the file associated with handle into the buffer pointed to by buf.

For a file opened in text mode, read removes carriage returns and reports end-of-file when it reaches a Ctrl-Z.

The file handle handle is obtained from a creat, open, dup, or dup2 call.

On disk files, read begins reading at the current file pointer. When the reading is complete, it increments the file pointer by the number of bytes read. On devices, the bytes are read directly from the device.

The maximum number of bytes that read can read is UINT_MAX -1, because UINT_MAX is the same as -1, the error return indicator. UINT_MAX is defined in limits.h.

Return Value

On successful completion, read returns an integer indicating the number of bytes placed in the buffer. If the file was opened in text mode, read does not count carriage returns or Ctrl-Z characters in the number of bytes read.

On end-of-file, read returns 0. On error, read returns -1 and sets the global variable errno to one of the following values:

EACCES	Permission denied
EBADF	Bad file number

Example

```
#include <stdio.h>
#include <io.h>
#include <alloc.h>
#include <fcntl.h>
#include <process.h>
#include <sys\stat.h>
int main(void)
{
   void *buf;
   int handle, bytes;
   buf = malloc(10);
/*
Looks for a file in the current directory named TEST.$$$ and attempts to read 10 bytes from
it. To use this example you should create the file TEST.$$$.
 */
   if ((handle =
      open("TEST.$$$", O_RDONLY | O_BINARY, S_IWRITE | S_IREAD)) == -1)
   {
      printf("Error Opening File\n");
      exit(1);
   }
   if ((bytes = read(handle, buf, 10)) == -1) {
      printf("Read Failed.\n");
      exit(1);
   }
   else {
      printf("Read: %d bytes read.\n", bytes);
   }
   return 0;
}
```

Portability

POSIX	Win32	ANSI C	ANSI C++
+	+		

3.1.4.15.31 setmode

Header File

io.h

Category

Input/output Routines

Prototype

```
int setmode(int handle, int amode);
```

Description

Sets mode of an open file.

setmode sets the mode of the open file associated with handle to either binary or text. The argument amode must have a value of either O_BINARY or O_TEXT, never both. (These symbolic constants are defined in fcntl.h.)

Return Value

setmode returns the previous translation mode if successful. On error it returns -1 and sets the global variable errno to

EINVAL	Invalid argument

Example

```
#include <fcntl.h>
#include <io.h>
#include <stdio.h>
int main (int argc, char ** argv )
(
  FILE *fp;
  int newmode;
  long where;
  char buf[256];
  fp = fopen( argv[1], "r+" );
  if ( !fp )
  {
    printf( "Couldn't open %s\n", argv[1] );
    return -1;
  }
  newmode = setmode( fileno( fp ), O_BINARY );
  if ( newmode == -1 )
  {
    printf( "Couldn't set mode of %s\n", argv[1] );
    return -2
  }
  fp->flags |= _F_BIN;
  where = ftell( fp );
  printf ("file position: %d\n", where );
  fread( buf, 1, 1, fp );
  where = ftell ( fp );
  printf( "read %c, file position: %ld\n", *buf, where );

3.1.4.15.32 tell

Header File

io.h

Category

Input/output Routines

Prototype

```
long tell(int handle);
```

Description

Gets the current position of a file pointer.

tell gets the current position of the file pointer associated with handle and expresses it as the number of bytes from the beginning of the file.

Return Value

tell returns the current file pointer position. A return of -1 (**long**) indicates an error, and the global variable errno is set to

EBADF	Bad file number

Example

```
#include <string.h>
#include <stdio.h>
#include <fcntl.h>
#include <io.h>
int main(void)
{
   int handle;
   char msg[] = "Hello world";
   if ((handle = open("TEST.$$$", O_CREAT | O_TEXT | O_APPEND)) == -1)
   {
      perror("Error:");
      return 1;
   }
   write(handle, msg, strlen(msg));
   printf("The file pointer is at byte %ld\n", tell(handle));
   close(handle);
   return 0;
}
```

Portability

	+		

3.1.4.15.33 umask

Header File

io.h, sys\stat.h

Category

Input/output Routines

Prototype

```
unsigned umask(unsigned mode);
```

Description

Sets file read/write permission mask.

The umask function sets the access permission mask used by open and creat. Bits that are set in mode will be cleared in the access permission of files subsequently created by open and creat.

The mode can have one of the following values, defined in sys\stat.h:

S_IWRITE	Permission to write
S_IREAD	Permission to read
S_IREAD|S_IWRITE	Permission to read and write

Return Value

The previous value of the mask. There is no error return.

Example

```
#include <io.h>
#include <stdio.h>
#include <sys\stat.h>
#define FILENAME "TEST.$$$"
int main(void)
{
    unsigned oldmask;
    FILE *f;
    struct stat statbuf;
    /* Cause subsequent files to be created as read-only */
    oldmask = umask(S_IWRITE);
    printf("Old mask = 0x%x\n",oldmask);
    /* Create a zero-length file */
    if ((f = fopen(FILENAME,"w+")) == NULL)
    {
        perror("Unable to create output file");
        return (1);
    }
    fclose(f);
    /* Verify that the file is read-only */
    if (stat(FILENAME,&statbuf) != 0)
    {
        perror("Unable to get information about output file");
        return (1);
    }
    if (statbuf.st_mode & S_IWRITE)
        printf("Error! %s is writable!\n",FILENAME);
    else
        printf("Success! %s is not writable.\n",FILENAME);
    return (0);
}
```

Portability

3.1.4.15.34 unlock

Header File

io.h

Category

Input/output Routines

Prototype

```
int unlock(int handle, long offset, long length);
```

Description

Releases file-sharing locks.

unlock provides an interface to the operating system file-sharing mechanism. unlock removes a lock previously placed with a call to lock. To avoid error, all locks must be removed before a file is closed. A program must release all locks before completing.

Return Value

On success, unlock returns 0

O error, it returns -1.

Example

```
#include <io.h>
#include <fcntl.h>
#include <sys\stat.h>
#include <process.h>
#include <share.h>
#include <stdio.h>
int main(void)
{
   int handle, status;
   long length;
   handle = _sopen("c:\\autoexec.bat",O_RDONLY,SH_DENYNO,S_IREAD);
   if (handle < 0)
   {
       printf("_sopen failed\n");
       exit(1);
   }
   length = filelength(handle);
   status = lock(handle,0L,length/2);
   if (status == 0)
      printf("lock succeeded\n");
   else
      printf("lock failed\n");
   status = unlock(handle,0L,length/2);
   if (status == 0)
      printf("unlock succeeded\n");
   else
      printf("unlock failed\n");
   close(handle);
   return 0;
}
```

3.1.4.15.35 vsscanf

Header File

io.h

Category

Memory and String Manipulation Routines

Prototype

```
int vsscanf(const char *buffer, const char *format, va_list arglist);
```

Description

Scans and formats input from a stream.

The v...scanf functions are known as alternate entry points for the ...scanf functions. They behave exactly like their ...scanf counterparts, but they accept a pointer to a list of arguments instead of an argument list.

Note: For details on format specifiers, see Scanf Format Specifiers.

vsscanf scans a series of input fields, one character at a time, reading from a stream. Then each field is formatted according to a format specifier passed to vsscanf in the format string pointed to by format. Finally, vsscanf stores the formatted input at an address passed to it as an argument following format. There must be the same number of format specifiers and addresses as there are input fields.

vsscanf might stop scanning a particular field before it reaches the normal end-of-field (whitespace) character, or it might terminate entirely, for a number of reasons. See scanf for a discussion of possible causes.

Return Value

vsscanf returns the number of input fields successfully scanned, converted, and stored; the return value does not include scanned fields that were not stored. If no fields were stored, the return value is 0.

If vsscanf attempts to read at end-of-string, the return value is EOF.

Example

```
#include <stdio.h>
#include <stdarg.h>
char buffer[80] = "30 90.0 abc";
int vssf(char *fmt, ...)
{
   va_list  argptr;
   int cnt;
   fflush(stdin);
   va_start(argptr, fmt);
   cnt = vsscanf(buffer, fmt, argptr);
   va_end(argptr);
   return(cnt);
}
int main(void)
{
   int inumber;
   float fnumber;
   char string[80];
   vssf("%d %f %s", &inumber, &fnumber, string);
   printf("%d %f %s\n", inumber, fnumber, string);
   return 0;
}
```

3.1.4.15.36 write

Header File

io.h

Category

Input/output Routines

Prototype

```
int write(int handle, void *buf, unsigned len);
```

Description

Writes to a file.

write writes a buffer of data to the file or device named by the given handle. handle is a file handle obtained from a creat, open, dup, or dup2 call.

This function attempts to write len bytes from the buffer pointed to by buf to the file associated with handle. Except when write is used to write to a text file, the number of bytes written to the file will be no more than the number requested. The maximum number of bytes that write can write is UINT_MAX -1, because UINT_MAX is the same as -1, which is the error return indicator for write. On text files, when write sees a linefeed (LF) character, it outputs a CR/LF pair. UINT_MAX is defined in limits.h.

If the number of bytes actually written is less than that requested, the condition should be considered an error and probably indicates a full disk. For disks or disk files, writing always proceeds from the current file pointer. For devices, bytes are sent directly to the device. For files opened with the O_APPEND option, the file pointer is positioned to EOF by write before writing the data.

Return Value

write returns the number of bytes written. A write to a text file does not count generated carriage returns. In case of error, write returns -1 and sets the global variable errno to one of the following values:

EACCES	Permission denied
EBADF	Bad file number

Example

```
#include <stdio.h>
#include <stdlib.h>
#include <fcntl.h>
#include <sys\stat.h>
#include <io.h>
#include <string.h>
int main(void)
{
   int handle;
   char string[40];
   int length, res;
/*
Create a file named "TEST.$$$" in the current directory and write a string to it.  If
"TEST.$$$" already exists, it will be overwritten.
 */
   if ((handle = open("TEST.$$$", O_WRONLY | O_CREAT | O_TRUNC,
                        S_IREAD | S_IWRITE)) == -1)
   {
      printf("Error opening file.\n");
      exit(1);
   }
   strcpy(string, "Hello, world!\n");
   length = strlen(string);
   if ((res = write(handle, string, length)) != length)
   {
      printf("Error writing to the file.\n");
      exit(1);
   }
   printf("Wrote %d bytes to the file.\n", res);
   close(handle);
```

```
    return 0;
}
```

3.1.4.16 limits.h

The following functions, macros, and classes are provided in `limits.h`:

Topics

Name	Description
CHAR_xxx #defines (see page 913)	**Header File** limits.h **Description**
INT_xxx #defines (see page 913)	**Header File** limits.h **Description** Maximum and minimum value for type int.
LONG_xxx #defines (see page 914)	**Header File** limits.h **Description** Maximum and minimum value for type long.
SCHAR_xxx #defines (see page 914)	**Header File** limits.h **Description**
SHRT_xxx #defines (see page 914)	**Header File** limits.h **Description**
Uxxxx_MAX #defines (see page 915)	**Header File** limits.h **Description**

3.1.4.16.1 CHAR_xxx #defines

Header File

limits.h

Description

Name	Meaning
CHAR_BIT	Type char, number of bits
CHAR_MAX	Type char, minimum value
CHAR_MIN	Type char, maximum value

These values are independent of whether type char is defined as signed or unsigned by default.

3.1.4.16.2 INT_xxx #defines

Header File

limits.h

Description

Maximum and minimum value for type int.

Name	Meaning
INT_MAX	Type int, maximum value
INT_MIN	Type int, minimum value

3.1.4.16.3 LONG_xxx #defines

Header File

limits.h

Description

Maximum and minimum value for type long.

Name	Meaning
LONG_MAX	Type long, maximum value
LONG_MIN	Type long, minimum value

3.1.4.16.4 SCHAR_xxx #defines

Header File

limits.h

Description

Name	Meaning
SCHAR_MAX	Type char, maximum value
SCHAR_MIN	Type char, minimum value

3.1.4.16.5 SHRT_xxx #defines

Header File

limits.h

Description

Name	Meaning
SHRT_MAX	Type short, maximum value
SHRT_MIN	Type short, minimum value

3.1.4.16.6 Uxxxx_MAX #defines

Header File

limits.h

Description

Name	Maximum value for type xxx
UCHAR_MAX	unsigned char
USHRT_MAX	unsigned short
UINT_MAX	unsigned integer
ULONG_MAX	unsigned long

3.1.4.17 locale.h

The following functions, macros, and classes are provided in `locale.h`:

Topics

Name	Description
localeconv (see page 915)	**Header File** locale.h **Category** Miscellaneous Routines **Prototype** `struct lconv *localeconv(void);` **Description** Queries the locale for numeric format. This function provides information about the monetary and other numeric formats for the current locale. The information is stored in a **struct** lconv type. The structure can only be modified by the setlocale. Subsequent calls to localeconv will update the lconv structure. The lconv structure is defined in locale.h. It contains the following fields:

setlocale, _wsetlocale (see page 917)	**Header File**
