addlift

Add lifting steps to lifting scheme

Syntax

```
LSN = addlift(LS,ELS)
LSN = addlift(LS,ELS,'begin')
LSN = addlift(LS,ELS,'end')
addfilt(LS,ELS)
```

Description

LSN = addlift(LS, ELS) returns the new lifting scheme LSN obtained by appending the elementary lifting step ELS to the lifting scheme LS.

```
LSN = addlift(LS, ELS, 'begin') prepends the specified elementary lifting step.
```

```
ELS is either a cell array (see lsinfo)
```

```
or a structure (see liftfilt)
```

{TYPEVAL, COEFS, MAX DEG}

```
struct('type',TYPEVAL,'value',LPVAL)
```

with

```
LPVAL = laurpoly(COEFS, MAX DEG)
```

```
LSN = addlift(LS, ELS, 'end') is equivalent to addfilt(LS, ELS).
```

If *ELS* is a sequence of elementary lifting steps, stored in a cell array or an array of structures, then each of the elementary lifting steps is added to *LS*.

For more information about lifting schemes, see lsinfo.

Add Primal Lifting Step

This example shows how to start with the Haar lifting scheme and add a primal lifting step.

```
LSbegin = liftwave('haar');
Display the lifting scheme.
displs(LSbegin);
LSbegin = {...}
                 [ -1.00000000] [0]
                 [ 0.50000000] [0]
[ 1.41421356] [ 0.70710678] []
};
Create a primal lifting step.
pstep = \{ 'p', [-1 \ 2 \ -1]/4, 1 \};
Add the primal lifting step.
LSend = addlift(LSbegin,pstep);
Display the final lifting scheme.
displs(LSend);
LSend = {...}
' d '
                 [-1.00000000]
                                                            [0]
                 [ 0.50000000]
                                                            [0]
                 [ -0.25000000 0.50000000 -0.25000000]
                                                            [1]
[ 1.41421356] [ 0.70710678]
                                                            []
};
```

allnodes

Tree nodes

Syntax

```
N = allnodes(T)
N = allnodes(T, 'deppos')
```

Description

allnodes is a tree management utility that returns one of two node descriptions: either indices, or depths and positions.

The nodes are numbered from left to right and from top to bottom. The root index is 0.

N = allnodes(T) returns the indices of all the nodes of the tree T in column vector N.

N = allnodes(T, 'deppos') returns the depths and positions of all the nodes in matrix N.

N(i,1) is the depth and N(i,2) the position of the node i.

Return Nodes of Wavelet Packet Tree

This example shows how to obtain the depth-position and linear indices of a wavelet packet tree.

Load the noisy Doppler signal and obtain the wavelet packet decomposition down to the level 4 using the 'db2' wavelet.

```
load noisdopp;
T = wpdec(noisdopp,4,'db2');
Obtain the depth-position indices.
DepthPosition = allnodes(T,'deppos');
```

Obtain the corresponding linear indices.

LinearIndices = allnodes(T);

Display the correspondance in a table.

table(DepthPosition,LinearIndices)

appcoef

1-D approximation coefficients

Syntax

```
A = appcoef(C,L,'wname',N)
A = appcoef(C,L,'wname')
A = appcoef(C,L,Lo_R,Hi_R)
A = appcoef(C,L,Lo_R,Hi_R,N)
```

Description

appcoef is a one-dimensional wavelet analysis function.

appcoef computes the approximation coefficients of a one-dimensional signal.

A = appcoef(C,L, 'wname', N) computes the approximation coefficients at level N using the wavelet decomposition structure [C,L] (see wavedec for more information).

'wname' is a string containing the wavelet name. Level N must be an integer such that $0 \le N \le length(L) - 2$.

A = appcoef(C,L,'wname') extracts the approximation coefficients at the last level: length(L) -2.

Instead of giving the wavelet name, you can give the filters.

For $A = \operatorname{appcoef}(C, L, Lo_R, Hi_R)$ or $A = \operatorname{appcoef}(C, L, Lo_R, Hi_R, N)$, Lo_R is the reconstruction low-pass filter and Hi_R is the reconstruction high-pass filter (see wfilters for more information).

Level 3 Approximation Coefficients

This example shows how to extract the level 3 approximation coefficients.

Load the signal consisting of electricity usage data.

```
load leleccum;
```

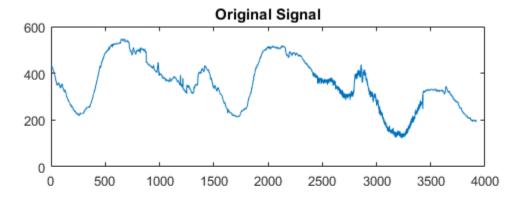

```
sig = leleccum(1:3920);
```

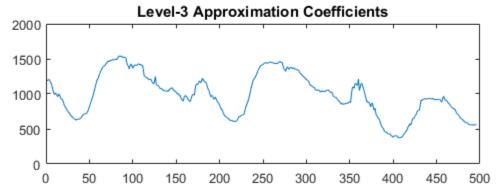

Obtain the DWT down to level 5 with the 'sym4' wavelet.

```
[C,L] = wavedec(sig,5,'sym4');
```

Extract the level-3 approximation coefficients. Plot the original signal and the approximation coefficients.

```
Lev = 3;
a3 = appcoef(C,L,'sym4',Lev);
subplot(2,1,1)
plot(sig); title('Original Signal');
subplot(2,1,2)
plot(a3); title('Level-3 Approximation Coefficients');
```

You can substitute any value from 1 to 5 for Lev to obtain the approximation coefficients for the corresponding level.

More About

Algorithms

The input vectors C and L contain all the information about the signal decomposition.

Let NMAX = length(L)-2; then $C = [A(NMAX) D(NMAX) \dots D(1)]$ where A and the D are vectors.

If N = NMAX, then a simple extraction is done; otherwise, appcoef computes iteratively the approximation coefficients using the inverse wavelet transform.

detcoef | wavedec

Introduced before R2006a

appcoef2

2-D approximation coefficients

Syntax

```
A = appcoef2(C,S,'wname',N)
A = appcoef2(C,S,'wname')
A = appcoef2(C,S,Lo_R,Hi_R)
A = appcoef2(C,S,Lo_R,Hi_R,N)
```

Description

appcoef2 is a two-dimensional wavelet analysis function. It computes the approximation coefficients of a two-dimensional signal. The syntaxes allow you to give the wavelet name or the filters as inputs.

A = appcoef2(C,S,'wname',N) computes the approximation coefficients at level N using the wavelet decomposition structure [C,S] (see wavedec2 for more information).

'wname' is a string containing the wavelet name. Level N must be an integer such that $0 \le N \le size(S,1)-2$.

A = appcoef2(C,S,'wname') extracts the approximation coefficients at the last level: size(S,1)-2.

A = appcoef2(C,S,Lo_R,Hi_R) or A = appcoef2(C,S,Lo_R,Hi_R,N), Lo_R is the reconstruction low-pass filter and Hi_R is the reconstruction high-pass filter (see wfilters for more information).

Examples

```
% The current extension mode is zero-padding (see dwtmode).
% Load original image.
load woman;
```

```
% X contains the loaded image.
% Perform decomposition at level 2
% of X using db1.
[c,s] = wavedec2(X,2,'db1');
sizex = size(X)
sizex =
    256 256
sizec = size(c)
sizec =
     1
           65536
    val s = s
val s =
    64
           64
    64
           64
   128
          128
   256
          256
% Extract approximation coefficients
% at level 2.
ca2 = appcoef2(c,s,'db1',2);
sizeca2 = size(ca2)
sizeca2 =
    64
           64
% Compute approximation coefficients
% at level 1.
ca1 = appcoef2(c,s,'db1',1);
sizeca1 = size(ca1)
sizeca1 =
          128
   128
```

More About

Tips

If C and S are obtained from an indexed image analysis or a truecolor image analysis, A is an m-by-n matrix or an m-by-n-by-3 array, respectively.

For more information on image formats, see the image and imfinfo reference pages.

Algorithms

The algorithm is built on the same principle as appcoef.

detcoef2 | wavedec2

Introduced before R2006a

bestlevt

Best level tree wavelet packet analysis

Syntax

```
T = bestlevt(T)
[T,E] = bestlevt(T)
```

Description

bestlevt is a one- or two-dimensional wavelet packet analysis function.

bestlevt computes the optimal complete subtree of an initial tree with respect to an entropy type criterion. The resulting complete tree may be of smaller depth than the initial one.

T = bestlevt(T) computes the modified wavelet packet tree T corresponding to the best level tree decomposition.

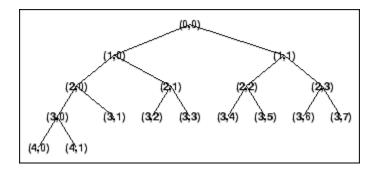

[T,E] = bestlevt(T) computes the best level tree T, and in addition, the best entropy value E.

The optimal entropy of the node, whose index is j-1, is E(j).

Examples

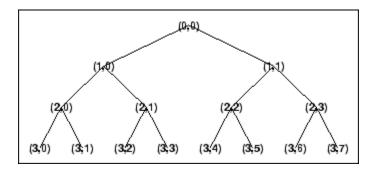

```
% The current extension mode is zero-padding (see dwtmode).
% Load signal.
load noisdopp;
x = noisdopp;
% Decompose x at depth 3 with db1 wavelet, using default
% entropy (shannon).
wpt = wpdec(x,3,'db1');
```

```
% Decompose the packet [3 0].
wpt = wpsplt(wpt,[3 0]);
% Plot wavelet packet tree wpt.
plot(wpt)
```

% Compute best level tree. blt = bestlevt(wpt);

% Plot best level tree blt. plot(blt)

More About

Algorithms

See besttree algorithm section. The only difference is that the optimal tree is searched among the complete subtrees of the initial tree, instead of among all the binary subtrees.

See Also

besttree | wpdec | wenergy | wpdec2

Introduced before R2006a

besttree

Best tree wavelet packet analysis

Syntax

```
T = besttree(T)
[T,E] = besttree(T)
[T,E,N] = besttree(T)
```

Description

besttree is a one- or two-dimensional wavelet packet analysis function that computes the optimal subtree of an initial tree with respect to an entropy type criterion. The resulting tree may be much smaller than the initial one.

Following the organization of the wavelet packets library, it is natural to count the decompositions issued from a given orthogonal wavelet.

A signal of length $N = 2^L$ can be expanded in α different ways, where α is the number of binary subtrees of a complete binary tree of depth L.

As a result, we can conclude that $\alpha \ge 2^{N/2}$ (for more information, see the Mallat's book given in References at page 323).

This number may be very large, and since explicit enumeration is generally intractable, it is interesting to find an optimal decomposition with respect to a convenient criterion, computable by an efficient algorithm. We are looking for a minimum of the criterion.

T = besttree(T) computes the best tree T corresponding to the best entropy value.

[T,E] = besttree(T) computes the best tree T and, in addition, the best entropy value E.

The optimal entropy of the node, whose index is j-1, is E(j).

[T,E,N] = besttree(T) computes the best tree T, the best entropy value E and, in addition, the vector N containing the indices of the merged nodes.

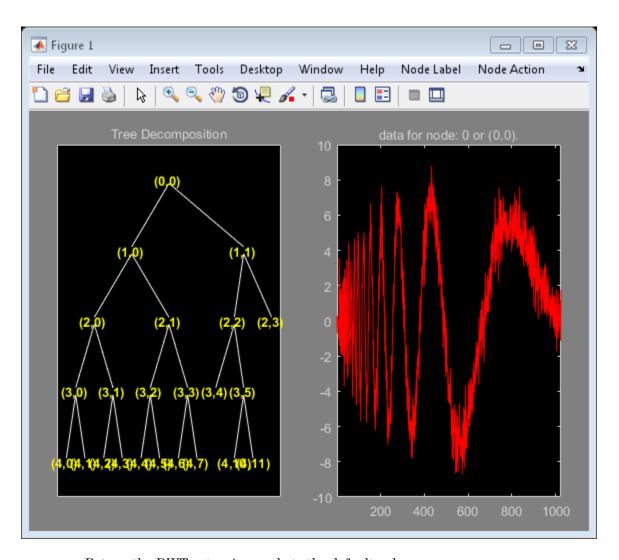

Best Wavelet Packet Tree

This example shows to obtain the optimal wavelet packet tree based on an entropy criterion.

Load the noisy Doppler signal. Obtain the wavelet packet tree down to level 4 with the 'sym4' wavelet. Use the periodic extension mode.

Obtain the best wavelet packet tree and plot the result.

```
BstTree = besttree(T);
plot(BstTree)
```

Return the DWT extension mode to the default value.

More About

Algorithms

Consider the one-dimensional case. Starting with the root node, the best tree is calculated using the following scheme. A node N is split into two nodes N1 and N2 if and only if the sum of the entropy of N1 and N2 is lower than the entropy of N. This is a local criterion based only on the information available at the node N.

Several entropy type criteria can be used (see wenergy for more information). If the entropy function is an additive function along the wavelet packet coefficients, this algorithm leads to the best tree.

Starting from an initial tree T and using the merging side of this algorithm, we obtain the best tree among all the binary subtrees of T.

Introduced before R2006a

biorfilt

Biorthogonal wavelet filter set

Syntax

```
[Lo_D,Hi_D,Lo_R,Hi_R] = biorfilt(DF,RF)
[Lo_D1,Hi_D1,Lo_R1,Hi_R1,Lo_D2,Hi_D2,Lo_R2,Hi_R2] =
biorfilt(DF,RF,'8')
```

Description

The biorfilt command returns either four or eight filters associated with biorthogonal wavelets.

 $[Lo_D, Hi_D, Lo_R, Hi_R] = biorfilt(DF, RF)$ computes four filters associated with the biorthogonal wavelet specified by decomposition filter DF and reconstruction filter RF. These filters are

Lo_D	Decomposition low-pass filter
Hi_D	Decomposition high-pass filter
Lo_R	Reconstruction low-pass filter
Hi_R	Reconstruction high-pass filter

```
[Lo_D1,Hi_D1,Lo_R1,Hi_R1,Lo_D2,Hi_D2,Lo_R2,Hi_R2] = biorfilt(DF,RF,'8') returns eight filters, the first four associated with the decomposition wavelet, and the last four associated with the reconstruction wavelet.
```

It is well known in the subband filtering community that if the same FIR filters are used for reconstruction and decomposition, then symmetry and exact reconstruction are incompatible (except with the Haar wavelet). Therefore, with biorthogonal filters, two wavelets are introduced instead of just one:

One wavelet, ψ , is used in the analysis, and the coefficients of a signal s are

$$\tilde{c}_{j,k} = \int s(x) \tilde{\psi}_{j,k}(x) dx$$

The other wavelet, ψ , is used in the synthesis:

$$s = \sum_{j,k} \tilde{c}_{j,k} \psi_{j,k}$$

Furthermore, the two wavelets are related by duality in the following sense:

$$\int \tilde{\psi}_{j,k}(x) \psi_{j',k'}(x) dx = 0 \text{ as soon as } j \neq j' \text{ or } k \neq k' \text{ and}$$
$$\int \tilde{\phi}_{0,k}(x) \phi_{0,k'}(x) dx = 0 \text{ as soon as } k \neq k'.$$

It becomes apparent, as A. Cohen pointed out in his thesis (p. 110), that "the useful properties for analysis (e.g., oscillations, null moments) can be concentrated in the ψ function; whereas, the interesting properties for synthesis (regularity) are assigned to the ψ function. The separation of these two tasks proves very useful."

 $ilde{\psi}$ and ψ can have very different regularity properties, ψ being more regular than $ilde{\psi}$.

The ψ , ψ , $\tilde{\phi}$ and ϕ functions are zero outside a segment.

Biorthogonal Filters and Transfer Functions

This example shows how to obtain the decompositition (analysis) and reconstruction (synthesis) filters for the 'bior3.5' wavelet.

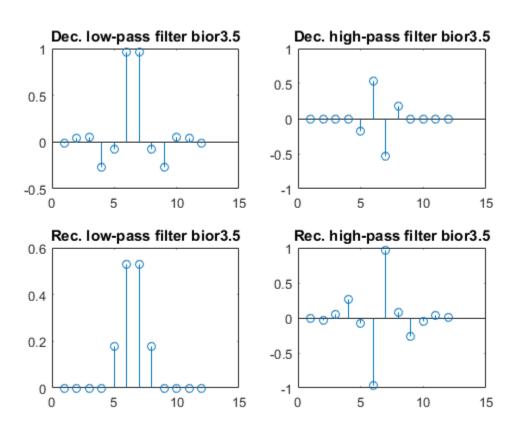

Determine the two scaling and wavelet filters associated with the 'bior3.5' wavelet.

```
[Rf,Df] = biorwavf('bior3.5');
[LoD,HiD,LoR,HiR] = biorfilt(Df,Rf);
```

Plot the filter impulse responses.

```
subplot(221); stem(LoD);
```

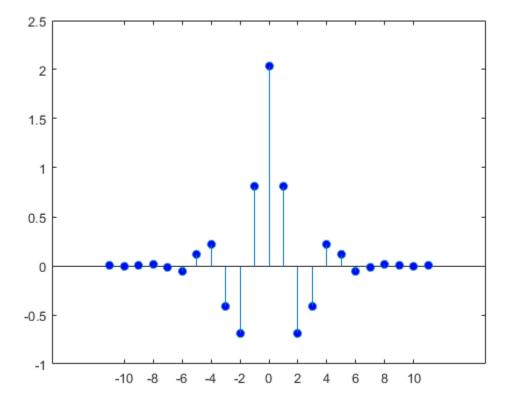

```
title('Dec. low-pass filter bior3.5');
subplot(222); stem(HiD);
title('Dec. high-pass filter bior3.5');
subplot(223); stem(LoR);
title('Rec. low-pass filter bior3.5');
subplot(224); stem(HiR);
title('Rec. high-pass filter bior3.5');
```

Demonstrate that autocorrelations at even lags are only zero for dual pairs of filters. Examine the autocorrelation sequence for the lowpass decomposition filter.

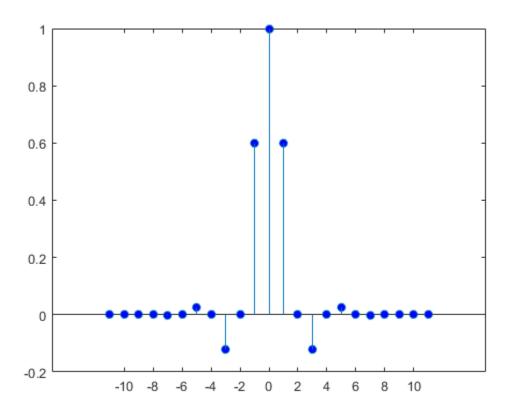

```
npad = 2*length(LoD)-1;
LoDxcr = fftshift(ifft(abs(fft(LoD,npad)).^2));
```

```
lags = -floor(npad/2):floor(npad/2);
figure;
stem(lags,LoDxcr,'markerfacecolor',[0 0 1])
set(gca,'xtick',-10:2:10)
```

Examine the cross correlation sequence for the lowpass decomposition and synthesis filters. Compare the result with the preceding figure.

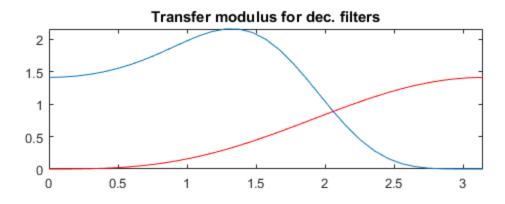

```
npad = 2*length(LoD)-1;
xcr = fftshift(ifft(fft(LoD,npad).*conj(fft(LoR,npad))));
lags = -floor(npad/2):floor(npad/2);
stem(lags,xcr,'markerfacecolor',[0 0 1])
set(gca,'xtick',-10:2:10)
```

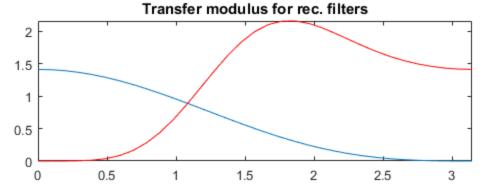

Compare the transfer functions of the analysis and synthesis scaling and wavelet filters

```
dftLoD = fft(LoD,64);
dftLoD = dftLoD(1:length(dftLoD)/2+1);
dftHiD= fft(HiD,64);
dftHiD = dftHiD(1:length(dftHiD)/2+1);
dftLoR = fft(LoR,64);
dftLoR = dftLoR(1:length(dftLoR)/2+1);
dftHiR = fft(HiR,64);
dftHiR = dftHiR(1:length(dftHiR)/2+1);
df = (2*pi)/64;
freqvec = 0:df:pi;
subplot(211); plot(freqvec,abs(dftLoD),freqvec,abs(dftHiD),'r');

biorwavf | orthfilt

biorwavf

Biorthogonal spline wavelet filter

Syntax

```
[RF,DF] = biorwavf(W)
```

Description

[RF,DF] = biorwavf(W) returns the reconstruction (synthesis) and decomposition (analysis) filters associated with the biorthogonal wavelet specified by the string W.

W = biorNr.Nd' where possible values for Nr and Nd are

Nr = 1	Nd = 1 , 3 or 5
Nr = 2	Nd = 2 , 4 , 6 or 8
Nr = 3	Nd = 1 , 3 , 5 , 7 or 9
Nr = 4	Nd = 4
Nr = 5	Nd = 5
Nr = 6	Nd = 8

The output arguments are filters.

- RF is the reconstruction filter.
- · DF is the decomposition filter.

Examples

Return the biorthogonal spline wavelet scaling filters with 2 vanishing moments.

```
wname = 'bior2.2';
[RF,DF] = biorwavf(wname);
```

bswfun

Biorthogonal scaling and wavelet functions

Syntax

```
[PHIS,PSIS,PHIA,PSIA,XVAL] = bswfun(LoD,HiD,LoR,HiR)
bswfun(LoD,HiD,LoR,HiR,ITER)
bswfun(LoD,HiD,LoR,HiR,'plot')
bswfun(LoD,HiD,LoR,HiR,ITER,'plot')
bswfun(LoD,HiD,LoR,HiR,'plot',ITER)
```

Description

[PHIS, PSIS, PHIA, PSIA, XVAL] = bswfun(LoD, HiD, LoR, HiR) returns approximations on the grid XVAL of the two pairs of biorthogonal scaling and wavelet functions. PHIS and PSIS are the scaling and wavelet functions constructed from the decomposition filters, LoD and HiD. PHIA and PSIA are the scaling and wavelet functions constructed from the reconstruction filters, LoR and HiR.

bswfun(LoD, HiD, LoR, HiR, ITER) computes the two pairs of scaling and wavelet functions using ITER iterations.

```
bswfun(LoD, HiD, LoR, HiR, 'plot') or bswfun(LoD, HiD, LoR, HiR, ITER, 'plot') or bswfun(LoD, HiD, LoR, HiR, 'plot', ITER) computes and plots the functions.
```

Examples

Biorthogonal Scaling and Wavelet from Lifting Scheme

This example shows how to obtain the biorthogonal scaling and wavelet functions corresponding to a lifting scheme. Obtain the lifting scheme for the CDF 3/1 wavelet.

```
lscdf = liftwave('cdf3.1');
```

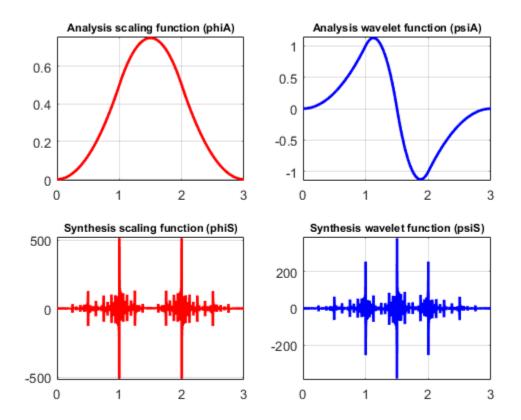

Display the lifting scheme, which consists of two primal and one dual step.

Obtain the decomposition and reconstruction filters from the lifting scheme.

```
[LoD,HiD,LoR,HiR] = ls2filt(lscdf);
```

Visualize the scaling and wavelet function and their duals.

```
bswfun(LoD,HiD,LoR,HiR,'plot');
```

More About

Algorithms

This function uses the cascade algorithm.

wavefun

centfrq

Wavelet center frequency

Syntax

```
FREQ = centfrq('wname')
FREQ = centfrq('wname',ITER)
[FREQ,XVAL,RECFREQ] = centfrq('wname',ITER,'plot')
```

Description

FREQ = centfrq('wname') returns the center frequency in herz of the wavelet function, 'wname' (see wavefun for more information).

For FREQ = centfrq('wname', ITER), ITER is the number of iterations performed by the function wavefun, which is used to compute the wavelet.

[FREQ,XVAL,RECFREQ] = centfrq('wname',ITER,'plot') returns, in addition, the associated center frequency based approximation RECFREQ on the $2^{\rm ITER}$ points grid XVAL and plots the wavelet function and RECFREQ.

Examples

Determine Center Frequency

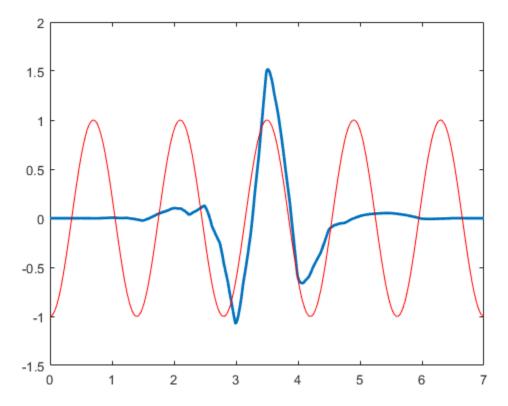

This example shows how to determine the center frequency in hertz for Daubechies' least-asymmetric wavelet with 4 vanishing moments.

```
cfreq = centfrq('sym4');
```

Obtain the wavelet and create a sine wave with a frequency equal to the center frequency, cfreq, of the wavelet. Use a starting phase of $-\pi$ for the sine wave to visualize how the oscillation in the sine wave matches the oscillation in the wavelet.

```
[~,psi,xval] = wavefun('sym4');
y = cos(2*pi*cfreq*xval-pi);
```

```
plot(xval,psi,'linewidth',2);
hold on;
plot(xval,y,'r');
```

Convert Scales to Frequencies

This example shows to convert scales to frequencies for the Morlet wavelet. There is an approximate inverse relationship between scale and frequency. Specifically, scale is inversely proportional to frequency with the constant of proportionality being the center frequency of the wavelet.

Construct a vector of scales with 32 voices per octave over 5 octaves for data sampled at 1 kHz.

```
Fs = 1000;
numvoices = 32;
a0 = 2^(1/numvoices);
numoctaves = 5;
scales = a0.^(numvoices:1/numvoices:numvoices*numoctaves).*1/Fs;
```

Convert the scales to approximate frequencies in hertz for the Morlet wavelet.

```
Frq = centfrq('morl')./scales;
```

You can also use scal2frq to convert scales to approximate frequencies in hertz.

scal2frq | wavefun

cfs2wpt

Wavelet packet tree construction from coefficients

Syntax

Description

CFS2WPT builds a wavelet packet tree (T) and the related analyzed signal or image (X) using the following input information:

WNAME: name of the wavelet used for the analysis

SIZE_OF_DATA: size of the analyzed signal or image

TN OF TREE: vector containing the terminal node indices of the tree

ORDER: 2 for a signal or 4 for an image

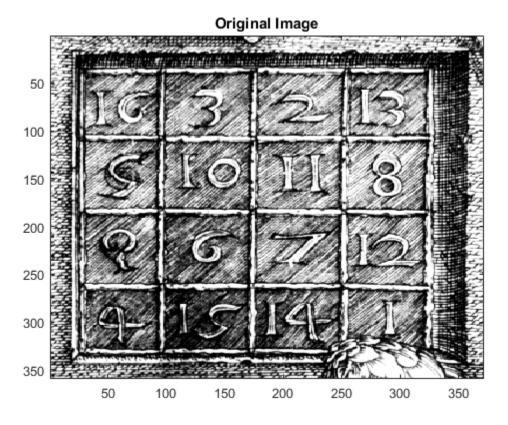

CFS: coefficients used to reconstruct the original signal or image. *CFS* is optional. When CFS2WPT is used without the *CFS* input parameter, the wavelet packet tree structure (T) is generated, but all the tree coefficients are null (including X).

Build Wavelet Packet Tree

This example shows how to build a wavelet packet tree in two ways: 1.) By filling the wavelet packet tree with coefficients, and 2.) By creating the wavelet packet tree and using write

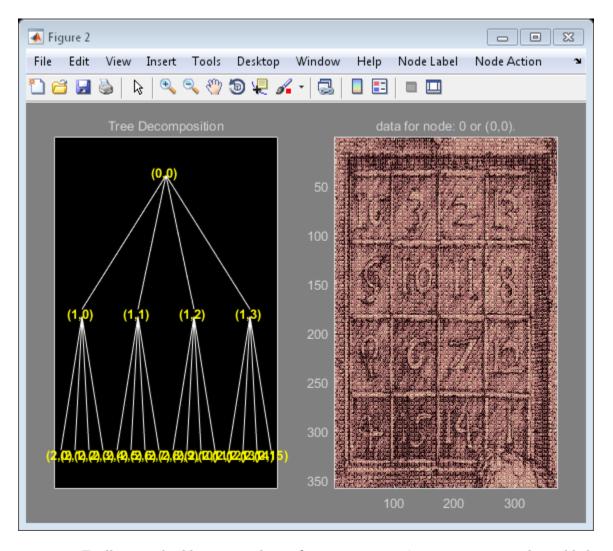

Load an image and obtain the wavelet packet decomposition down to level 2 with the 'sym4' wavelet.

```
load detail;
imagesc(X); colormap gray; title('Original Image');
Tr = wpdec2(X,2,'sym4');
```

Read the coefficients from the wavelet packet tree. Add $N(0,40^2)$ noise to the coefficients and plot the new wavelet packet tree.

```
cfs = read(Tr, 'allcfs');
noisyCfs = cfs + 40*rand(size(cfs));
noisyT = cfs2wpt('sym4',size(X),tnodes(Tr),4,noisyCfs);
plot(noisyT)
```

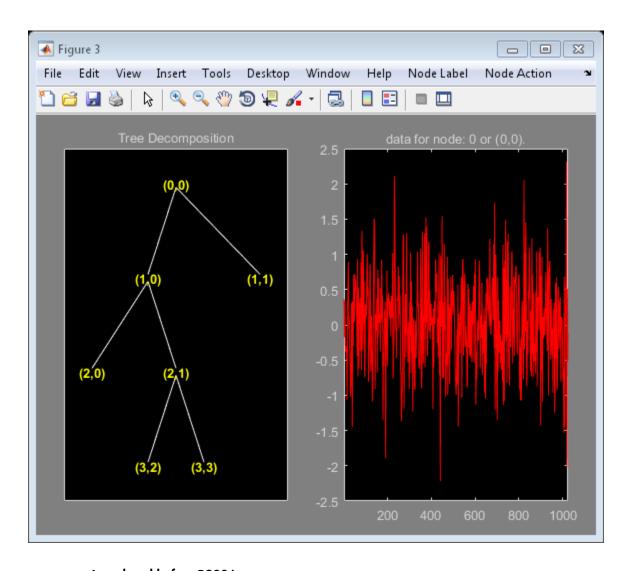

To illustrate building a wavelet packet tree using write, construct an admissible binary wavelet packet tree with terminal nodes [2 3 9 10]. The analyzing wavelet is 'sym4' and the signal length is 1024.

tr = cfs2wpt('sym4',[1 1024],[2 3 9 10]',2);

Fill terminal nodes [3 9] with N(0,1) coefficients.

```
sN = read(tr,'sizes',[3,9]);
sN3 = sN(1,:); sN9 = sN(2,:);
cfsN3 = randn(sN3);
cfsN9 = randn(sN9);
tr = write(tr,'cfs',3,cfsN3,'cfs',9,cfsN9);
Plot the resulting wavelet packet tree and synthesized signal.
plot(tr)
```

Introduced before R2006a

cgauwavf

Complex Gaussian wavelet

Syntax

```
[PSI,X] = cgauwavf(LB,UB,N,P)
[PSI,X] = cgauwavf(LB,UB,N)
[PSI,X] = cgauwavf(LB,UB,N,1)
```

Description

[PSI,X] = cgauwavf(LB,UB,N,P) returns values of the P-th derivative of the complex Gaussian function on an N point regular grid for the interval [LB,UB].

For P > 8, Symbolic Math ToolboxTM software is required.

Output arguments are the wavelet function PSI computed on the grid X.

```
[PSI,X] = cgauwavf(LB,UB,N) is equivalent to
[PSI,X] = cgauwavf(LB,UB,N,1).
```

These wavelets have an effective support of [-5 5].

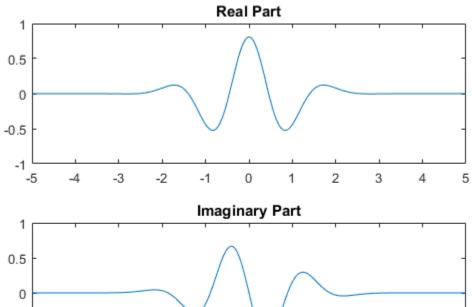

Examples

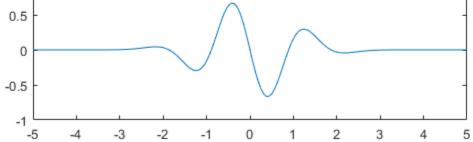

Create Complex Gaussian Wavelet

This example shows how to create a complex-valued Gaussian wavelet of order 4. The wavelet has an effective support of [-5,5] and is constructed using 1,000 samples.

```
lb = -5;
ub = 5;
n = 1000;
order = 4;
[psi,x] = cgauwavf(lb,ub,n,order);
subplot(211)
```

```
plot(x,real(psi))
title('Real Part');
subplot(212)
plot(x,imag(psi))
title('Imaginary Part');
```

chgwdeccfs

Change multisignal 1-D decomposition coefficients

Syntax

```
DEC = chgwdeccfs(DEC, 'ca', COEFS)
DEC = chgwdeccfs(DEC, 'cd', COEFS, LEV)
DEC = chgwdeccfs(DEC, 'all', CA, CD)
DEC = chgwdeccfs(DEC, 'all', V)
DEC = chgwdeccfs(..., IDXSIG)
```

Description

DEC = chgwdeccfs(DEC, 'ca', COEFS) replaces the approximation coefficients at level DEC.level with those contained in the matrix COEFS. If COEFS is a single value V, all coefficients are replaced by V.

DEC = chgwdeccfs(DEC, 'cd', COEFS, LEV) replaces the detail coefficients at level LEV with those contained in the matrix COEFS. If COEFS is a single value V, then LEV can be a vector of levels and all the coefficients that belong to these levels are replaced by V. LEV must be such that $1 \le \text{LEV} \le \text{DEC.level}$

DEC = chgwdeccfs(DEC, 'all',CA,CD) replaces all the approximation and detail coefficients. CA must be a matrix and CD must be a cell array of length DEC.level.

If COEFS (or *CA* or *CD*) is a single number, then it replaces all the related coefficients. Otherwise, COEFS (or *CA*, or *CD*) must be a matrix of appropriate size.

For a real value V, DEC = chgwdeccfs(DEC, 'all', V) replaces all the coefficients by V.

DEC = chgwdeccfs(...,IDXSIG) replaces the coefficients for the signals whose indices are given by the vector IDXSIG. If the initial data are stored row-wise or columnwise in a matrix X, then IDXSIG contains the row or column indices, respectively, of the data.

Examples

```
% Load original 1D-multisignal
load thinker
% Perform a decomposition at level 2 using wavelet db2
dec = mdwtdec('r',X,2,'db2');
% Change the coefficients of details at level 1.
% Replace all values by 0.
decBIS = chgwdeccfs(dec, 'cd',0,1);
% Change the coefficients of details at level 1 and
% level 2 for signals 31 to 35. Replace all values by 0.
decTER = chgwdeccfs(dec, 'cd', 0, 1:2, 31:35);
% Compare original and new coefficients for details
% at level 1 for signals 31 to 35.
plot(dec.cd{1}(31:35,:)','b'); hold on;
plot(decTER.cd{1}(31:35,:)','r')

cmddenoise

Interval-dependent denoising

Syntax

```
sigden = cmddenoise(sig,wname,level)
sigden = cmddenoise(sig,wname,level,sorh)
sigden = cmddenoise(sig,wname,level,sorh,nb_inter)
sigden = cmddenoise(sig,wname,level,sorh,nb_inter,thrParamsIn)
[sigden,coefs] = cmddenoise(____)
[sigden,coefs,thrParamsOut] = cmddenoise(____)
[sigden,coefs,thrParamsOut,int_DepThr_Cell] = cmddenoise(sig,wname,level,sorh,nb_inter)
[sigden,coefs,thrParamsOut,int_DepThr_Cell,BestNbofInt] = cmddenoise(sig,wname,level,sorh,nb_inter)
```

Description

sigden = cmddenoise(sig,wname,level) returns the denoised signal, sigden, obtained from an interval-dependent denoising of the signal, sig, using the orthogonal or biorthogonal wavelet and scaling filters, wname. cmddenoise thresholds the wavelet (detail) coefficients down to level, level, and reconstructs a signal approximation using the modified detail coefficients. cmddenoise partitions the signal into intervals based on variance change points in the first level detail coefficients and thresholds each interval separately. The location and number of variance change points are automatically selected using a penalized contrast function [2]. The minimum delay between change points is 10 samples. Thresholds are obtained using a minimax threshold rule and soft thresholding is used to modify the wavelet coefficients [1].

sigden = cmddenoise(sig,wname,level,sorh) returns the denoised signal,
sigden, using the thresholding method, sorh, to modify the wavelet coefficients. Valid
choices for sorh are 's' for soft thresholding or 'h' for hard thresholding.

sigden = cmddenoise(sig,wname,level,sorh,nb_inter) returns the denoised
signal, sigden, with the number of denoising intervals as a positive integer between

1 and 6: $1 \le \text{nb_inter} \le 6$. For $\text{nb_inter} \ge 2$, cmddenoise estimates the location of the change points with a contrast function [2].

sigden = cmddenoise(sig,wname,level,sorh,nb_inter,thrParamsIn) returns the denoised signal, sigden, with the denoising intervals and corresponding thresholds specified as a cell array of matrices with length equal to level. Each element of the cell array contains the interval and threshold information for the corresponding level of the wavelet transform. The elements of thrParamsIn are N-by-3 matrices with N equal to the number of intervals. The 1st and 2nd columns contain the beginning and ending indices of the intervals and the 3rd column contains the corresponding threshold value. If you specify thrParamsIn, cmddenoise ignores the value of nb inter.

[sigden,coefs] = cmddenoise(____) returns the approximation (scaling) and detail (wavelet) coefficients, coefs. The organization of coefs is identical to the structure returned by wavedec. This syntax can include any of the input arguments used in previous syntaxes.

[sigden,coefs,thrParamsOut] = cmddenoise(____) returns a cell array, thrParamsOut, with length equal to level. Each element of thrParamsOut is an N-by-3 matrix. The row dimension of the matrix elements is the number of intervals and is determined by the value of the input arguments. Each row of the matrix contains the beginning and end points (indices) of the thresholded interval and the corresponding threshold value.

[sigden,coefs,thrParamsOut,int_DepThr_Cell] = cmddenoise(sig,wname, level,sorh,nb_inter) returns a cell array, int_DepThr_Cell, with length equal to 6. int_DepThr_Cell contains interval and threshold information assuming the number of change points ranges from 0 to 5. The N-th element of int_DepThr_Cell is a N-by-3 matrix containing the interval information assuming N-1 change points. Each row of the matrix contains the beginning and end points (indices) of the thresholded interval and the corresponding threshold value. Attempting to output int_DepThr_Cell if you use the input argument, thrParamsIn, results in an error.

[sigden,coefs,thrParamsOut,int_DepThr_Cell,BestNbofInt] = cmddenoise(sig,wname,level,sorh,nb_inter) returns the optimal number of signal intervals based on the estimated variance change points in the level-1 detail coefficients. To estimate the number of change points, cmddenoise assumes the total number is less than or equal to 6 and uses a penalized contrast [2]. Attempting to output BestNbofInt if you use the input argument, thrParamsIn, results in an error.

Examples

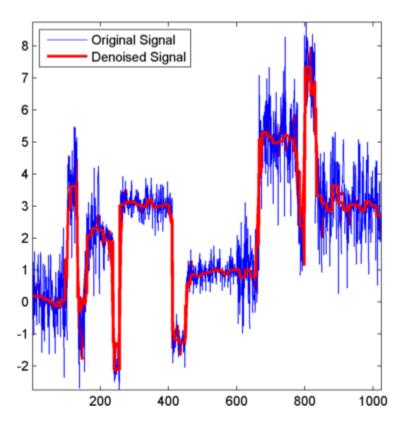

Denoising Blocks Signal with Haar Wavelet

Load the noisy blocks signal, nblocr1.mat. The signal consists of a piecewise constant signal in additive white Gaussian noise. The variance of the additive noise differs in three disjoint intervals.

```
load nblocr1;
```

Apply interval-dependent denoising down to level 4 using the Haar wavelet. **cmddenoise** automatically determines the optimal number and locations of the variance change points. Plot the denoised and original signal for comparison.

```
sigden = cmddenoise(nblocr1,'db1',4);
plot(nblocr1);
hold on;
plot(sigden,'r','linewidth',2);
axis tight;
legend('Original Signal','Denoised Signal','Location','NorthWest');
```

Denoising Blocks Signal with Hard Thresholding

Load the noisy blocks signal, nblocr1.mat. The signal consists of a piecewise constant signal in additive white Gaussian noise. The variance of the additive noise differs in three disjoint intervals.

```
load nblocr1;
```

Apply interval-dependent denoising down to level 4 using the Haar wavelet and a hard thresholding rule. cmddenoise automatically determines the optimal number and locations of the intervals. Plot the original and denoised signals.

```
sorh = 'h';
sigden = cmddenoise(nblocr1, 'db1',4,sorh);
plot(nblocr1);
hold on;
```

```
plot(sigden,'r','linewidth',2);
axis tight;
legend('Original Signal','Denoised Signal','Location','NorthWest');
```

Specify the Number of Intervals

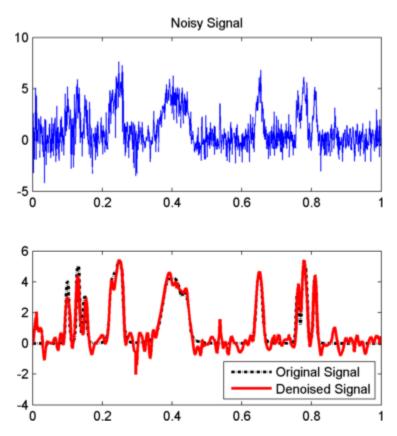

Create a signal sampled at 1 kHz. The signal consists of a series of bumps of various widths.

Add white Gaussian noise with different variances to two disjoint segments of the signal. Add zero-mean white Gaussian noise with variance equal to 2 to the signal segment from 0 to 0.3 seconds. Add zero-mean white Gaussian noise with unit variance to the signal segment from 0.3 seconds to 1 second. Set the random number generator to the default settings for reproducible results.

```
rng default;
nv1 = sqrt(2).*randn(size(tt)).*(tt<=0.3);
nv2 = randn(size(tt)).*(tt>0.3);
xx = x+nv1+nv2;
```

Apply interval-dependent denoising using the Daubechies' least-asymmetric wavelet with 5 vanishing moments down to level 3. Set the number of intervals to 2. Plot the noisy signal, original signal, and denoised signal for comparison.

```
sigden = cmddenoise(xx,'sym5',3,'s',2);
subplot(211)
plot(tt,xx); title('Noisy Signal');
subplot(212)
plot(tt,x,'k-.','linewidth',2);
hold on;
plot(tt,sigden,'r','linewidth',2);
legend('Original Signal','Denoised Signal','Location','SouthEast');
```

Specify Intervals and Thresholds

Load the example signal nbumpr1.mat. The variance of the additive noise differs in three disjoint intervals.

```
load nbumpr1.mat;
```

Use a level-5 multiresolution analysis. Create a cell array of length 5 consisting of 3-by-3 matrices. The first two elements of each row contain the beginning and ending indices of the interval and the last element of each row is the corresponding threshold.

```

};
```

Denoise the signal using the threshold settings and the Daubechies' least-asymmetric wavelet with 4 vanishing moments. Use a soft thresholding rule. Plot the noisy and denoised signals for comparison.

```
wname = 'sym4';
level = 5;
sorh = 's';
sigden = cmddenoise(nbumpr1,wname,level,sorh,NaN,...
    thrParamsIn);
plot(nbumpr1); hold on;
plot(sigden,'r','linewidth',2); axis tight;
legend('Noisy Signal','Denoised Signal','Location','NorthEast');
```

Return Denoised Wavelet Coefficients

Load the example signal nblocr1.mat. Use the Haar wavelet and decompose the signal down to level 2. Obtain the discrete wavelet transform and denoise the signal. Return the wavelet coefficients of the noisy and denoised signals.

```
load nblocr1.mat;
[sigden,coefs] = cmddenoise(nblocr1,'db1',2);
[C,L] = wavedec(nblocr1,2,'db1');
```

Plot reconstructions based on the level-2 approximation and level-2 and level-1 detail coefficients for the noisy signal.

```
app = wrcoef('a',C,L,'db1',2);
subplot(3,1,1);
plot(app); title('Approximation Coefficients');
```

```
for nn = 1:2
    det = wrcoef('d',C,L,'db1',nn);
    subplot(3,1,nn+1)
    plot(det);

                                                       1200
```

The approximation coefficients are identical in the noisy and denoised signal, but most of the detail coefficients in the denoised signal are close to zero.

Output Intervals and Thresholds

Create a signal sampled at 1 kHz. The signal consists of a series of bumps of various widths.

```
t = [0.1 \ 0.13 \ 0.15 \ 0.23 \ 0.25 \ 0.40 \ 0.44 \ 0.65 \ 0.76 \ 0.78 \ 0.81];
```

Add white Gaussian noise with different variances to two disjoint segments of the signal. Add zero-mean white Gaussian noise with variance equal to 2 to the signal segment from 0 to 0.3 seconds. Add zero-mean white Gaussian noise with unit variance to the signal segment from 0.3 seconds to 1 second. Set the random number generator to the default settings for reproducible results.

```
rng default;
nv1 = sqrt(2).*randn(size(tt)).*(tt<=0.3);
nv2 = randn(size(tt)).*(tt>0.3);
xx = x+nv1+nv2;
```

Apply interval-dependent denoising using the Daubechies' least-asymmetric wavelet with 4 vanishing moments down to level 5. Automatically choose the number of intervals and output the result.

```
[sigden,coefs,thrParamsOut] = cmddenoise(xx,'sym4',5);
thrParamsOut{1}
```

cmddenoise identifies one variance change point in the 1st level detail coefficients defining two intervals. The first interval contains samples 1 to 293. The second interval contains samples 293 to 1000. This is close to the true variance change point, which occurs at sample 299.

Partition Signal into Increasing Numbers of Intervals with Thresholds

Load the example signal, nbumpr1.mat. Partition the signal into 1 to 6 intervals assuming 0 to 5 change points. Compute the thresholds for each interval. Using the Daubechies' least-asymmetric wavelet with 4 vanishing moments return the intervals and corresponding thresholds. Display the results in the command window.

```
load nbumpr1.mat;
[sigden,~,~,int_DepThr_Cell] = cmddenoise(nbumpr1,'sym4',1);
format bank;
```

```
disp(' Begin End Threshold ');
cellfun(@disp,int_DepThr_Cell,'UniformOutput',false);
format;
```

Detect Number of Change Points

Load the example signal, nbumpr1.mat. The signal has two variance change points, which results in three intervals.

Use cmddenoise to detect the number of change points. Print the result.

```
load nbumpr1.mat;
[sigden,~,thrParamsOut,~,bestNbofInt] = ...
  cmddenoise(nbumpr1,'sym4',1);
fprintf('Found %d change points.\n',bestNbofInt-1);
```

Input Arguments

sig — Signal for interval-dependent denoising

1-D row or column vector

Input signal, specified as a 1-D row or column vector. Sig is the real-valued input signal for interval-dependent denoising. The elements of Sig are assumed to be equally spaced in time or space. If Sig contains unequally-sampled data, cmddenoise is not appropriate. Use a lifting transform instead. See 1wt for details.

Data Types: double

wname - Wavelet name

string

Wavelet name, specified as a character array. wname is any valid orthogonal or biorthogonal wavelet. You can use the command: wtype = wavemngr('fields',wname,'type','file'); to determine if the wavelet name is valid to use with cmddenoise. Valid wavelet names return a 1 or 2 for wtype.

```
Example: 'bior2.2', 'db4', 'sym4'
Data Types: char
```

1evel — Level of the decimated wavelet transform (multiresolution analysis)

positive integer

Wavelet transform (multiresolution analysis) level, specified as a positive integer. level gives the level of the multiresolution decomposition of the input signal using the decimated 1-D discrete wavelet transform, wavedec.

Data Types: double

sorh - Threshold rule

's' (default) | 'h'

Thresholding rule, specified as a character array. sorh is the threshold rule used in the modification of the detail coefficients. Valid choices for sorh are 's' (default) and 'h' for soft and hard thresholding.

nb inter — Number of intervals

positive integer in the set $\{1,2,3,4,5,6\}$ | NaN

Number of intervals, specified as a positive integer less than 7. cmddenoise divides the input signal into nb_inter intervals. cmddenoise determines the location of the nb_inter change points using a contrast function [2]. If you enter NaN for nb_inter, cmddenoise ignores the input. If you use the input argument thrParamsIn, cmddenoise disregards any value you enter for nb_inter.

Data Types: double

thrParamsIn — Intervals and thresholds by level

cell array of matrices

Intervals and thresholds by level, specified as a cell array of matrices equal in length to level. Each element of thrParamsIn contains the interval and threshold information for the corresponding level of the multiresolution analysis. The elements of thrParamsIn are N-by-3 matrices with N equal to the number of intervals. The 1st and 2nd columns contain the beginning and ending indices of the intervals and the 3rd column contains the corresponding threshold value. If you specify thrParamsIn, you cannot specify the output arguments int_DepThr_Cell or BestNbofInt.

Data Types: cell

Output Arguments

sigden — Denoised signal

1-D row or column vector

sigden is the denoised version of the input sig. sigden is a 1-D row vector equal in length to sig.

coefs — Approximation coefficients and thresholded wavelet coefficients

1-D row vector of approximation coefficients and thresholded wavelet coefficients

coefs is a row vector of approximation (scaling) and thresholded detail (wavelet) coefficients. The ordering of the approximation and detail coefficients by level in coefs is the same as the output of wavedec. cmddenoise does not apply thresholding to the approximation coefficients.

Data Types: double

thrParamsOut — Intervals and thresholds by level

cell array of matrices

thrParamsOut is a cell array of matrices equal in length to level. Each element of the cell array contains the interval and threshold information for the corresponding level of the multiresolution analysis. The elements of thrParamsOut are N-by-3 matrices with N equal to the number of intervals. N is determined by the value of the input arguments. The 1st and 2nd columns contain the beginning and ending indices of the intervals and the 3rd column contains the corresponding threshold value.

Data Types: cell

int_DepThr_Ce11 — Intervals and thresholds assuming 0 to 5 change points cell array of matrices

int_DepThr_Cell contains interval and threshold information assuming the number of change points ranges from 0 to 5. The N-th element of int_DepThr_Cell is a N-by-3 matrix containing the interval information assuming N-1 change points. Each row of the matrix contains the beginning and ending indices of the thresholded interval and the corresponding threshold value. Attempting to output int_DepThr_Cell if you input the number of intervals and thresholds, thrParamsIn, results in an error. int_DepThr_Cell{BestNbofInt} or int_DepThr_Cell{nb_inter} is equal to the matrix elements of thrParamsOut.

Data Types: cell

BestNbofInt - Optimal number of intervals

positive integer ≤6

BestNbofInt is the optimal number of intervals based on estimated change points in the variance of the level-1 detail coefficients. The number and location of the change points are estimated using a penalized contrast method [2]. Attempting to output BestNbofInt if you input the number of intervals and thresholds, thrParamsIn, results in an error.

Introduced in R2010a

cmorwayf

Complex Morlet wavelet

Syntax

```
[PSI,X] = cmorwavf(LB,UB,N,FB,FC)
```

Description

[PSI,X] = cmorwavf(LB,UB,N,FB,FC) returns values of the complex Morlet wavelet defined by a positive bandwidth parameter FB, a wavelet center frequency FC, and the expression

```
PSI(X) = ((pi*FB)^{(-0.5)})*exp(2*i*pi*FC*X)*exp(-X^2/FB)
```

on an N point regular grid for the interval [LB,UB].

Output arguments are the wavelet function PSI computed on the grid X.

Complex Morlet Wavelet

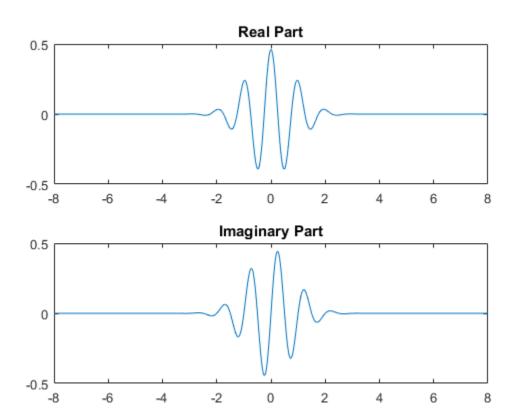

Construct a complex-valued Morlet wavelet with a bandwidth parameter of 1.5 and a center frequency of 1. Set the effective support to [-8,8] and the length of the wavelet to 1000.

```
N = 1000;
Lb = -8;
Ub = 8;
fb = 1.5;
fc = 1;
[psi,x] = cmorwavf(Lb,Ub,N,fb,fc);
```

Plot the real and imaginary parts of the wavelet.

```
subplot(2,1,1)
plot(x,real(psi)); title('Real Part');
subplot(2,1,2)
```

coifwavf

Coiflet wavelet filter

Syntax

```
F = coifwavf(W)
```

Description

F = coifwavf(W) returns the scaling filter associated with the Coiflet wavelet specified by the string W where W = 'coifN'. Possible values for N are 1, 2, 3, 4, or 5.

Examples

```
% Set coiflet wavelet name.
wname = 'coif2';
% Compute the corresponding scaling filter.
f = coifwavf(wname)

f =
Columns 1 through 7
0.0116 -0.0293 -0.0476 0.2730 0.5747 0.2949 -0.0541

Columns 8 through 12
-0.0420 0.0167 0.0040 -0.0013 -0.0005
```

conofinf

Cone of influence

Syntax

```
cone = conofinf(wname,scales,LenSig,SigVal)
[cone,PL,PR] = conofinf(wname,scales,LenSig,SigVal)
[cone,PL,PR,PLmin,PRmax] = conofinf(wname,scales,LenSig,SigVal)
[PLmin,PRmax] = conofinf(wname,scales,LenSig)
[...] = conofinf(...,'plot')
```

Description

cone = conofinf(wname, scales, LenSig, SigVal) returns the cone of influence (COI) for the wavelet wname at the scales in scales and positions in SigVal. LenSig is the length of the input signal. If SigVal is a scalar, cone is a matrix with row dimension length(scales) and column dimension LenSig. If SigVal is a vector, cone is cell array of matrices.

[cone,PL,PR] = conofinf(wname,scales,LenSig,SigVal) returns the left and right boundaries of the cone of influence at scale 1 for the points in SigVal. PL and PR are length(SigVal)-by-2 matrices. The left boundaries are(1-PL(:,2))./PL(:,1) and the right boundaries are(1-PR(:,2))./PR(:,1).

[cone,PL,PR,PLmin,PRmax] = conofinf(wname,scales,LenSig,SigVal) returns the equations of the lines that define the minimal left and maximal right boundaries of the cone of influence. PLmin and PRmax are 1-by-2 row vectors where PLmin(1) and PRmax(1) are the slopes of the lines. PLmin(2) and PRmax(2) are the points where the lines intercept the scale axis.

[PLmin, PRmax] = conofinf (wname, scales, LenSig) returns the slope and intercept terms for the first-degree polynomials defining the minimal left and maximal right vertices of the cone of influence.

```
[...] = conofinf(..., 'plot') plots the cone of influence.
```

Input Arguments

wname

wname is a string corresponding to a valid wavelet. To verify that wname is a valid wavelet, wavemngr('fields', wname) must return a struct array with a type field of 1 or 2, or a nonempty bound field.

scales

scales is a vector of scales over which to compute the cone of influence. Larger scales correspond to stretched versions of the wavelet and larger boundary values for the cone of influence.

LenSig

LenSig is the signal length and must exceed the maximum of SigVal.

SigVal

SigVal is a vector of signal values at which to compute the cone of influence. The largest value of SigVal must be less than the signal length, LenSig.If SigVal is empty, conofinf returns the slope and intercept terms for the minimal left and maximal right vertices of the cone of influence.

Output Arguments

cone

cone is the cone of influence. If SigVal is a scalar, cone is a matrix. The row dimension is equal to the number of scales and column dimension equal to the signal length, LenSig. If SigVal is a vector, cone is a cell array of matrices. The elements of each row of the matrix are equal to 1 in the interval around SigVal corresponding to the cone of influence.

PL

PL is the minimum value of the cone of influence on the position (time) axis.

PR

PR is the maximum value of the cone of influence on the position (time) axis.

PLmin

PLmin is a 1-by-2 row vector containing the slope and scale axis intercept of the line defining the minimal left vertex of the cone of influence. PLmin(1) is the slope and PLmin(2) is the point where the line intercepts the scale axis.

PRmax

PRmax is a 1-by-2 row vector containing the slope and scale axis intercept of the line defining the maximal right vertex of the cone of influence. PRmax(1) is the slope and PRmax(2) is the point where the line intercepts the scale axis.

Examples

Cone of influence for Mexican hat wavelet:

```
load cuspamax
signal = cuspamax;
wname = 'mexh';
scales = 1:64;
lenSIG = length(signal);
x = 500;
figure;
cwt(signal,scales,wname,'plot');
hold on
[cone,PL,PR,Pmin,Pmax] = conofinf(wname,scales,lenSIG,x,'plot');
set(gca,'Xlim',[1 lenSIG])
```

Left minimal and right maximal vertices for the cone of influence (Morlet wavelet):

```
[PLmin,PRmax] = conofinf('morl',1:32,1024,[],'plot');
% PLmin = -0.1245*u+ 32.0000
% PRmax = 0.1250*u-96.0000
```

More About

Cone of Influence

Let $\psi(t)$ be an admissible wavelet. Assume that the effective support of $\psi(t)$ is [-B,B]. Letting u denote the translation parameter and s denote the scale parameter, the dilated and translated wavelet is:

$$\psi_{u,s}(t) = \frac{1}{\sqrt{s}} \psi(\frac{t-u}{s})$$

andhas effective support [u-sB,u+sB]. The cone of influence (COI) is the set of all *t* included in the effective support of the wavelet at a given position and scale. This set is equivalent to:

$$|t-u| \le sB$$

At each scale, the COI determines the set of wavelet coefficients influenced by the value of the signal at a specified position.

cwt | wavsupport

Introduced in R2010b

cwt

Continuous 1-D wavelet transform

Syntax

```
coefs = cwt(x,scales,'wname')
coefs = cwt(x,scales,'wname','plot')
coefs = cwt(x,scales,'wname','coloration')
coefs = cwt(x,scales,'wname','coloration',xlim)
[coefs,sgram] = cwt(x,scales,'wname','scal')
[coefs,sgram] = cwt(x,scales,'wname','scalCNT')
[coefs,frequencies] = cwt(x,scales,wname, samplingperiod)
[coefs,sgram,frequencies] = cwt(x,scales,wname, samplingperiod,'scal')
```

Description

coefs = cwt(x,scales,'wname') returns the continuous wavelet transform (CWT) of the real-valued signal S. The wavelet transform is computed for the specified scales using the analyzing wavelet wname. scales is a 1-D vector with positive elements. The string wname denotes a wavelet recognized by wavemngr. coefs is a matrix with the number of rows equal to the length of scales and number of columns equal to the length of the input signal. The k-th row of coefs corresponds to the CWT coefficients for the k-th elemens in the scales vector.

coefs = cwt(x, scales, 'wname', 'plot') plots the continuous wavelet transform coefficients, using default coloration 'absglb'.

coefs = cwt(x,scales,'wname','coloration') uses the specified coloration. See
"Definitions" on page 1- for coloration options.

coefs = cwt(x,scales,'wname','coloration',xlim) colors the coefficients using coloration and xlim, where xlim is a vector, [x1 x2], with $1 \le x1 < x2 \le length(x)$.

[coefs,sgram] = cwt(x,scales,'wname','scal') returns and plots the scalogram. 'scal' produces an image plot of the scalogram.

[coefs,sgram] = cwt(x,scales,'wname','scalCNT') displays a contour representation of the scalogram.

[coefs,frequencies] = cwt(x,scales,wname, samplingperiod) returns the frequencies in cycles per unit time corresponding to the scales and the analyzing wavelet wname. samplingperiod is a positive real-valued scalar. If the units of samplingperiod are seconds, the frequencies are in hertz.

[coefs,sgram,frequencies] = cwt(x,scales,wname, samplingperiod,'scal') returns the scalogram and the frequencies corresponding to the scales and the analyzing wavelet. You can also use the flag 'scalCNT' to output the scalogram if you have at least two elements in scales. The samplingperiod is only used in the conversion of scales to frequencies. Specifying samplingperiod does not affect the appearance of plots generated by cwt.

Examples

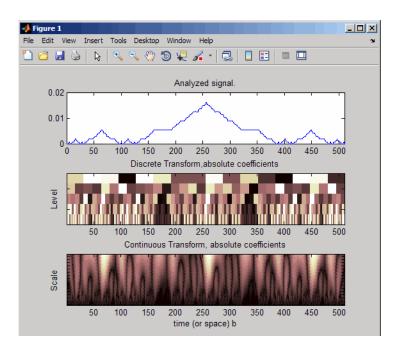

Plot the continuous wavelet transform and scalogram using sym2 wavelet at all integer scales from 1 to 32, using a fractal signal as input:

```
load vonkoch
vonkoch=vonkoch(1:510);
len = length(vonkoch);
cw1 = cwt(vonkoch,1:32,'sym2','plot');
title('Continuous Transform, absolute coefficients.')
ylabel('Scale')
[cw1,sc] = cwt(vonkoch,1:32,'sym2','scal');
title('Scalogram')
ylabel('Scale')
```

Compare discrete and continuous wavelet transforms, using a fractal signal as input:

```
load vonkoch
vonkoch=vonkoch(1:510);
len=length(vonkoch);
[c,1]=wavedec(vonkoch,5,'sym2');
% Compute and reshape DWT to compare with CWT.
cfd=zeros(5,len);
for k=1:5
    d=detcoef(c,l,k);
    d=d(ones(1,2^k),:);
```

```
cfd(k,:)=wkeep(d(:)',len);
end
cfd=cfd(:);
I=find(abs(cfd) <sqrt(eps));</pre>
cfd(I)=zeros(size(I));
cfd=reshape(cfd,5,len);
% Plot DWT.
subplot(311); plot(vonkoch); title('Analyzed signal.');
set(gca, 'xlim', [0 510]);
subplot(312);
image(flipud(wcodemat(cfd,255,'row')));
colormap(pink(255));
set(gca,'yticklabel',[]);
title('Discrete Transform, absolute coefficients');
ylabel('Level');
% Compute CWT and compare with DWT
subplot(313);
ccfs=cwt(vonkoch,1:32,'sym2','plot');
title('Continuous Transform, absolute coefficients');
set(gca,'yticklabel',[]);
vlabel('Scale');
```

How To

"Continuous and Discrete Wavelet Transforms"

"1-D Continuous Wavelet Analysis"

"New Wavelet for CWT"

"Time-Frequency Analysis with the Continuous Wavelet Transform"

More About

Scale values

Scale values determine the degree to which the wavelet is compressed or stretched. Low scale values compress the wavelet and correlate better with high frequencies. The low scale CWT coefficients represent the fine-scale features in the input signal vector. High scale values stretch the wavelet and correlate better with the low frequency content of the signal. The high scale CWT coefficients represent the coarse-scale features in the input signal.

Coloration

Coloration is the method used to scale the coefficient values for plotting. Each coefficient is divided by the resulting coloration value.

- 'lvl' uses maximum value in each scale
- 'qlb' uses maximum value in all scales
- · 'abslvl' or 'lvlabs' uses maximum absolute value in each scale
- · 'absglb' or 'glbabs' uses maximum absolute value in all scales
- 'scal' produces a scaled image of the scalogram
- 'scalCNT' produces a contour representation of the scalogram

For 3-D plots (surfaces), use the coloration parameter preceded by '3D', such as coefs = cwt(..., '3Dplot') or coefs = cwt(..., '3Dlvl') ...

Scalogram

Scalograms are plots that represent the percentage energy for each coefficient.

Introduced before R2006a

cwtft

Continuous wavelet transform using FFT algorithm

Syntax

```
cwtstruct = cwtft(sig)
cwtstruct = cwtft(sig,Name,Value)
cwtstruct = cwtft(...,'plot')
```

Description

cwtstruct = cwtft(sig) returns the continuous wavelet transform (CWT) of the 1-D input signal sig. cwtft uses an FFT algorithm to compute the CWT. sig can be a vector, a structure array, or a cell array. If the sampling interval of your signal is not equal to 1, you must input the sampling period with sig in a cell array or a structure array to obtain correct results. If sig is a cell array, sig{1} is equal to your signal and sig{2} is equal to the sampling interval. If sig is a structure array, the field sig.val contains your signal and sig.period contains the sampling interval.

By default, cwtft uses the analytic Morlet wavelet. See More About for descriptions of valid analyzing wavelets.

For additional default values, see scales in "Name-Value Pair Arguments" on page 1-77.

cwtstruct = cwtft(sig,Name,Value) returns the continuous wavelet transform (CWT) of the 1-D input signal sig with additional options specified by one or more Name,Value pair arguments. See "Name-Value Pair Arguments" on page 1-77 for a comprehensive list.

cwtstruct = cwtft(..., 'plot') plots the continuous wavelet transform. If the analyzing wavelet is real-valued, the original signal along with the CWT coefficient magnitudes and signed CWT coefficients are plotted. If the analyzing wavelet is complex-valued, the original signal is plotted along with the moduli, real parts, imaginary parts, and angles of the CWT coefficients. You can select the radio button in the bottom left of the plot to superimpose the signal's reconstruction using icwtft.

Input Arguments

sig

The 1-D input signal. Sig can be a vector, a structure array, or a cell array. If Sig is a structure array, Sig contains two fields: val and period. Sig.val is the signal vector and Sig.period is the sampling period. If Sig is a cell array, Sig{1} is the signal vector and Sig{2} is the sampling period.

If sig is a vector, the sampling period defaults to 1.

Note: If the sampling interval of your input signal is not 1, you must input the sampling interval with sig in a cell array or structure array to obtain correct results. If sig is a cell array, sig{1} is the 1-D input signal and sig{2} is the sampling period. If sig is a structure array, the field sig.val is the 1-D input signal and sig.period is the sampling interval.

Name-Value Pair Arguments

'scales'

Scales over which to compute the CWT. The value of scales can be a vector, a structure array, or a cell array. If scales is a structure array, it contains at most five fields. The first three fields are mandatory. The last two fields are optional.

- 1 s0 The smallest scale. The default s0 depends on the wavelet. See the More About for descriptions of the default for each wavelet.
- ds Spacing between scales. The default ds depends on the wavelet. See the More About for descriptions of the default for eacj wavelet. You can construct a linear or logarithmic scale vector using ds. See type for a description of the type of spacing.
- 3 nb Number of scales. The default nb depends on the wavelet. See the More About for descriptions of the default for each wavelet.
- 4 type Type of spacing between scales. type can be one of 'pow' or 'lin'. The default is 'pow'. If type is equal to 'pow', the CWT scales are s0*pow.^((0:nb-1)*ds). This results in a constant spacing of ds if you take the logarithm to the base power of the scales vector. If type is equal to 'lin', the CWT scales are linearly spaced by s0 + (0:nb-1)*ds.

Use the default power of two spacing to ensure an accurate approximation to the original signal based only on select scales. See the second example in "Examples" on page 1-79 for a signal approximation based on select scales.

5 pow — The base for 'pow' spacing. The default is 2. This input is valid only if the type argument is 'pow'.

If scales is a cell array, the first three elements of the cell array are identical to the first three elements of the structure array described in the preceding list. The last two elements of the cell array are optional and match the two optional inputs in the structure array described in the preceding list.

'wavelet'

Analyzing wavelet. The supported analyzing wavelets are:

- 'dog' *m*-th order derivative of a Gaussian wavelet where *m* is a positive even integer. The default value of *m* is 2.
- 'morl' Morlet wavelet. Results in an analytic Morlet wavelet. The Fourier transform of an analytic wavelet is zero for negative frequencies.
- 'morlex' non-analytic Morlet wavelet
- 'mor10' non-analytic Morlet wavelet with zero mean
- 'mexh' Mexican hat wavelet. The Mexican hat wavelet is a special case of the *m*-th order derivative of a Gaussian wavelet with *m*=2.
- 'paul' Paul wavelet
- 'bump' Bump wavelet

See the More About for formal definitions of the supported analyzing wavelets and associated defaults.

Default: 'morl'

'padmode'

Signal extension mode. See dwtmode for supported extension modes. By default, cwtft does not extend the signal prior to computing the CWT. In a Fourier-transform-based CWT algorithm, extending a signal can mitigate wrap-around effects. The number of CWT coefficients in each row of the output matrix cwtstruct.cfs is truncated to match the length of the input signal.

Output Arguments

cwtstruct

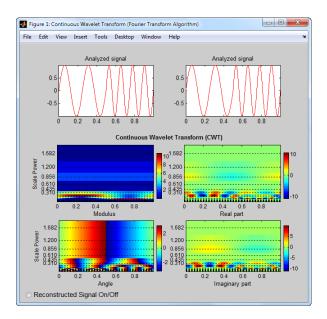

A structure array with six fields. The fields of the structure array are:

- cfs The CWT coefficient matrix. cwtstruct.cfs is an nb-by-N matrix where nb is the number of scales and N is the length of the input signal.
- scales Vector of scales at which the CWT is computed. The length of cwtstruct.scales is equal to the row dimension of cwtstruct.cfs.
- frequencies Frequencies in cycles per unit time (or space) corresponding to the scales. If the sampling period units are seconds, the frequencies are in hertz. The elements of frequencies are in decreasing order to correspond to the elements in the scales vector. Use this field to examine the CWT in the time-frequency plane.
- omega Vector of angular frequencies used in the Fourier transform of the wavelet.
 This field is used in icwtft and icwtlin for the inversion of the CWT for all wavelets except the bump wavelet.
- meanSIG Mean of the analyzed signal
- dt The sampling interval of the 1–D input signal
- wav Analyzing wavelet

Examples

Compute and display the CWT of sine waves with disjoint support. The sampling interval is 1/1023.

```
N = 1024;
% Sampling interval is 1/1023
t = linspace(0,1,N);
y = sin(2*pi*4*t).*(t<=0.5)+sin(2*pi*8*t).*(t>0.5);
% Because the sampling interval differs from the default
% you must input it along with the signal
% Using cell array input
sig = {y,1/1023};
cwtS1 = cwtft(sig, 'plot');
```

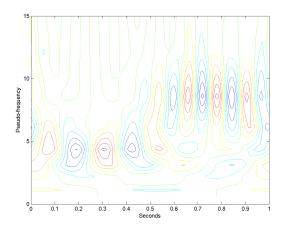

You can display or hide the reconstructed signal using the radio button at the bottom left of the figure. When you select the radio button, the maximum and quadratic relative errors are computed and displayed along with the reconstructed signal.

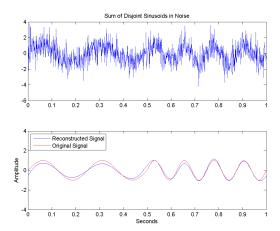

Reconstruct an approximation to a sum of disjoint sine waves in noise using cwtft to decompose the signal and icwtft to reconstruct the approximation. Use the CWT coefficients to identify the scales isolating the sinusoidal components. Reconstruct an approximation to the signal based on those scales using the inverse CWT. To ensure an accurate approximation to the based on select scales, use the default power of two spacing in the CWT.

```
rng default % Reset random number generator for reproducible results
N = 1024;
% Sampling interval is 1/1023
t = linspace(0,1,N);
y = sin(2*pi*4*t).*(t<=0.5)+sin(2*pi*8*t).*(t>0.5);
ynoise = y+randn(size(t));
% Because the sampling interval differs from the default
% you must input it along with the signal
% Using structure array input
sig = struct('val',ynoise,'period',1/1023);
cwtS1 = cwtft(sig);
```

```
scales = cwtS1.scales;
MorletFourierFactor = 4*pi/(6+sqrt(2+6^2));
freq = 1./(scales.*MorletFourierFactor);
contour(t,freq,real(cwtS1.cfs));
xlabel('Seconds'); ylabel('Pseudo-frequency');
axis([0 t(end) 0 15]);
```

Extract the scales dominated by energy from the two sine waves and reconstruct a signal approximation using the inverse CWT.

Alternatives

cwt — Computes the CWT using convolutions. cwt supports a wider choice of
analyzing wavelets than cwtft, but may be more computationally expensive. The
output of cwt is not compatible with the inverse CWT implemented with icwtft. To
use icwtft, obtain the CWT with cwtft.

More About

Morlet Wavelet

Both non-analytic and analytic Morlet wavelets are supported. The analytic Morlet wavelet, 'morl', is defined in the Fourier domain by:

$$\Psi(s\omega) = \pi^{-1/4} e^{-(s\omega - \omega_0)^2/2} U(s\omega)$$

where $U(\omega)$ is the Heaviside step function [5].

The non-analytic Morlet wavelet, 'morlex', is defined in the Fourier domain by:

$$\Psi(s\omega) = \pi^{-1/4} e^{-(s\omega - \omega_0)^2/2}$$

'morlo' defines a non-analytic Morlet wavelet in the Fourier domain with exact zero mean:

$$\Psi(s\omega) = \pi^{-1/4} \{ e^{-(s\omega - \omega_0)^2/2} - e^{-\omega_0^2/2} \}$$

The default value of ω_0 is 6.

The default smallest scale for the Morlet wavelets is s0 = 2*dt where dt is the sampling period.

The default spacing between scales for the Morlet wavelets is ds=0.4875.

The default number of scales for the Morlet wavelets is NbSc = fix(log2(length(sig)*dt/s0)/ds).

The default scales for the Morlet wavelet are s0*2.^((0:NbSc-1)*ds).

m-th Order Derivative of Gaussian Wavelets

In the Fourier domain, the m-th order derivative of Gaussian wavelets, 'dog', are defined by:

$$\hat{\Psi}(s\omega) = -\frac{1}{\sqrt{\Gamma(m+1/2)}} (js\omega)^m e^{-(s\omega)^2/2}$$

where $\Gamma()$ denotes the gamma function [5].

The derivative must be an even order. The default order of the derivative is 2, which is also known as the Mexican hat wavelet.

The default smallest scale for the DOG wavelet is s0 = 2*dt where dt is the sampling period.

The default spacing between scales for the DOG wavelet is ds=0.4875.

The default number of scales for the DOG wavelet is NbSc = fix(log2(length(sig)*dt/s0)/ds).

The default scales for the DOG wavelet are $s0*2.^((0:NbSc-1)*ds)$.

Paul Wavelet

The Fourier transform of the analytic Paul wavelet, 'paul', of order *m* is:

$$\hat{\Psi}(s\omega) = 2^m \sqrt{m(2m-1)!} (s\omega)^m e^{-s\omega} U(s\omega)$$

where $U(\omega)$ is the Heaviside step function [5].

The default order of the Paul wavelet is 4.

The default smallest scale for the Paul wavelet is s0 = 2*dt where dt is the sampling period.

The default spacing between scales for the Paul wavelet is ds=0.4875.

The default number of scales for the Paul wavelet is NbSc = fix(log2(length(sig)*dt/s0)/ds).

The default scales for the Paul wavelet are s0*2.^((0:NbSc-1)*ds).

Bump wavelet

The Fourier transform of the analytic bump wavelet, 'bump', with parameters μ and σ is

$$\widetilde{\psi}(s\omega) = e^{\left(1 - \frac{1}{1 - (s\omega - \mu)^2 / \sigma^2}\right)} \quad 1_{\left[(\mu - \sigma)/s, (\mu + \sigma)/s\right]}$$

where $\mathbf{1}_{[(\mu-\sigma)/s,\;(\mu+\sigma)/s]}$ is the indicator function for the interval $(\mu-\sigma)/s \leq \omega \leq (\mu+\sigma)/s$.

Valid values for μ are [3,6]. Valid values for σ are [0.1, 1.2]. Smaller values of σ result in a wavelet with superior frequency localization but poorer time localization. Larger values of σ produce a wavelet with better time localization and poorer frequency localization.

The default values for μ and σ are 5 and 0.6 respectively.

The default smallest scale for the bump wavelet is s0 = 2*dt where dt is the sampling period.

The default spacing between scales for the bump wavelet is ds=1/10.

The default number of scales for the bump wavelet is NbSc = fix(log2(length(sig)*dt/s0)/ds).

The default scales for the bump wavelet are s0*2.^((0:NbSc-1)*ds).

Algorithms

cwtft implements the following algorithm:

- Obtain the discrete Fourier transform (DFT) of the signal using fft.
- Obtain the DFT of the analyzing wavelet at the appropriate angular frequencies. Scale the DFT of the analyzing wavelet at different scales to ensure different scales are directly comparable.
- Take the product of the signal DFT and the wavelet DFT over all the scales. Invert the DFT to obtain the CWT coefficients.

For a mathematical motivation for the FFT-based algorithm see "Continuous Wavelet Transform and Scale-Based Analysis".

Valid analyzing wavelets for FFT-based CWT

Syntax

cwtftinfo

Description

cwtftinfo displays expressions for the Fourier transforms of valid analyzing wavelets for use with cwtft.

Examples

Display a list of Fourier transforms for all valid analyzing wavelets.

cwtftinfo

More About

Morlet Wavelet

Both non-analytic and analytic Morlet wavelets are supported. The analytic Morlet wavelet, 'morl', is defined in the Fourier domain by:

$$\Psi(s\omega) = \pi^{-1/4} e^{-(s\omega - \omega_0)^2/2} U(s\omega)$$

where $U(\omega)$ is the Heaviside step function.

The non-analytic Morlet wavelet, 'morlex', is defined in the Fourier domain by:

'morlo' defines a non-analytic Morlet wavelet in the Fourier domain with exact zero mean:

The default value of ω_0 is 6.

m-th Order Derivative of Gaussian Wavelets

In the Fourier domain, the m-th order derivative of Gaussian wavelets, 'dog', is defined by:

$$\hat{\Psi}(s\omega) = -\frac{1}{\sqrt{\Gamma(m+1/2)}} (js\omega)^m e^{-(s\omega)^2/2}$$

The derivative must be an even order. The default order of the derivative is 2, which is also known as the *Mexican hat* wavelet.

Because the unit imaginary, j, is always raised to an even power, the Fourier transform is real-valued.

Paul Wavelet

The Fourier transform of the Paul wavelet, 'paul', of order *m* is:

$$\hat{\Psi}(s\omega) = 2^m \sqrt{m(2m-1)!} (s\omega)^m e^{-s\omega} U(s\omega)$$

where $U(\omega)$ is the Heaviside step function. The Paul wavelet is analytic.

The default order of the Paul wavelet is 4.

Bump wavelet

The Fourier transform of the analytic bump wavelet, 'bump', with parameters μ and σ is

$$\widetilde{\psi}(s\omega) = e^{\left(1 - \frac{1}{1 - (s\omega - \mu)^2 / \sigma^2}\right)} \quad 1_{\left[(\mu - \sigma)/s, (\mu + \sigma)/s\right]}$$

where $\mathbb{I}[(\mu-\sigma)/s, (\mu+\sigma)/s]$ is the indicator function for the interval $(\mu-\sigma)/s \le \omega \le (\mu+\sigma)/s$.

Valid values for μ are [3,6]. Valid values for σ are [0.1, 1.2]. Smaller values of σ result in a wavelet with superior frequency localization but poorer time localization. Larger values of σ produce a wavelet with better time localization and poorer frequency localization.

The default values for μ and σ are 5 and 0.6 respectively.

cwtftinfo2

Supported 2-D CWT wavelets and Fourier transforms

Syntax

cwtftinfo2
cwtftinfo2(wname)

Description

cwtftinfo2 lists the supported 2-D continuous wavelet transform (CWT) wavelets and corresponding parameters for use with cwtft2.

cwtftinfo2(wname) displays the equation for the 2-D Fourier transform of the wavelet, wname. The figure with the 2-D Fourier transform of the analyzing wavelet has a drop-down list from which you can select other wavelets.

Examples

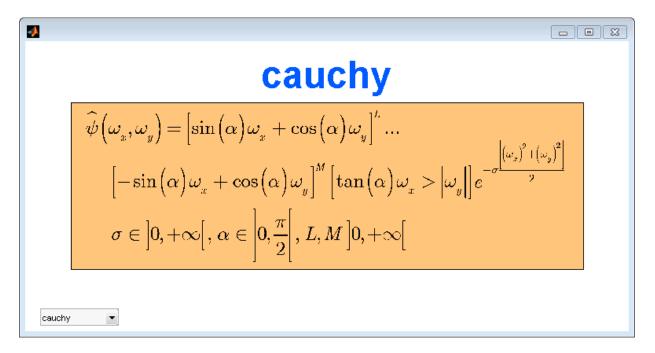

Available Wavelets with Parameters

cwtftinfo2

Display the Expression for the 2-D Fourier Transform

Display the expression for the 2-D Fourier transform of the Cauchy wavelet.

```
cwtftinfo2('cauchy')
```

After displaying the Fourier transform for any wavelet, you can use the drop-down list in the bottom left to view the Fourier transform for any supported wavelet.

Input Arguments

wname - Wavelet name

string

Wavelet name, specified as a string. The following table lists the supported wavelets for the 2-D CWT and associated parameters:

Wavelet name	Parameters
'morl'	{'Omega0',6;'Sigma',1;'Epsilon',1}
'mexh'	{'p',2;'sigmax',1;'sigmay',1}
'paul'	{'p',4}
'dog'	{'alpha',1.25}

Wavelet name	Parameters
'cauchy'	{'alpha','pi/6';'L',4;'M',4;'sigma',1}
'escauchy'	{'alpha','pi/6';'L',4;'M',4;'sigma',1}
'gaus'	{'p',1;'sigmax',1;'sigmay',1}
'wheel'	{'sigma',2}
'fan'	{'OmegaOX',5.336;'Sigma',1;'Epsilon',1;'J'
'pethat'	None
'dogpow'	{'alpha',1.25;'p',2}
'esmorl'	{'OmegaO',6;'Sigma',1;'Epsilon',1}
'esmexh'	{'Sigma',1;'Epsilon',0.5}
'gaus2'	{'p',1;'sigmax',1;'sigmay',1}
'gaus3'	{'A',1;'B',1;'p',1;'sigmax',1;'sigmay',1}
'isodog'	{'alpha',1.25,1.25}
'dog2'	{'alpha',1.25,1.25}
'isomorl'	{'OmegaO',6;'Sigma',1}
'rmorl'	{'OmegaO',6;'Sigma',1;'Epsilon',1}
'endstop1'	{'OmegaO',6}
'endstop2'	{'OmegaO',6;'Sigma',1}
'gabmexh'	{'OmegaO',5.336;'Epsilon',1}
'sinc'	{'Ax',1;'Ay',1;'p',1;'OmegaOX',0;'OmegaOY'

Example: cwtftinfo2('paul')

Data Types: char

cwtft2

2-D continuous wavelet transform

Syntax

```
cwtstruct = cwtft2(x)
cwtstruct = cwtft2(x,'plot')
cwtstruct = cwtft2(x,Name,Value)
```

Description

cwtstruct = cwtft2(x) returns the 2-D continuous wavelet transform (CWT) of the 2-D matrix, x. cwtft2 uses a Fourier transform-based algorithm in which the 2-D Fourier transforms of the input data and analyzing wavelet are multiplied together and inverted.

```
cwtstruct = cwtft2(x, 'plot') plots the data and the 2-D CWT.
```

cwtstruct = cwtft2(x,Name,Value) uses additional options specified by one or more Name,Value pair arguments.

Examples

Compare Isotropic and Anisotropic Wavelets

This example shows how an isotropic wavelet does not discern the orientation of features while an anisotropic wavelet does. The example uses the Mexican hat isotropic wavelet and the directional (anisotropic) Cauchy wavelet.

Load and view the hexagon image.

```
Im = imread('hexagon.jpg');
imagesc(Im); colormap(jet);
```

Obtain the scale-one 2-D CWT with both the Mexican hat and Cauchy wavelets. Specify a vector of angles going from 0 to $15\pi/8$ in $\pi/8$ increments.

```
cwtcauchy = cwtft2(Im, 'wavelet', 'cauchy', 'scales',1,...
```

Plot 2-D CWT

end

pause(1);

Load an image of a woman, obtain the 2-D CWT using the Morlet wavelet, and plot the CWT coefficients.

```
load woman;
cwtmorl = cwtft2(X,'scales',1:4,'angles',0:pi/2:3*pi/2,'plot');
```

2-D CWT with Morlet Wavelet

Obtain the 2-D CWT of the star image using the default Morlet wavelet, scales 2^(0:5), and an angle of 0.

```
Im = imread('star.jpg');
cwtout = cwtft2(Im);
```

- "Two-Dimensional CWT of Noisy Pattern"
- "2-D Continuous Wavelet Transform App"

Input Arguments

```
x — Input data
```

array

Input data, specified as a 2-D matrix or 3-D array. If the input data is a 3-D array, the input matrix is a truecolor image.

```
Example: X = imread('stars.jpg');
Data Types: double | uint8
```

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'wavelet', 'paul', 'scales', 2^(0:5) specifies to use the Paul wavelet and a vector of scales.

```
'angles' — Angles
0 (default) | scalar | vector
```

Angles in radians, specified as a comma-separated pair consisting of 'angles' and either a scalar or a vector.

```
Example: 'angles',[0 pi/2 pi]
'norm' — Normalization
'L2' (default) | 'L1' | 'L0'
```

Normalization used in the 2-D CWT, specified as a comma-separated pair consisting of 'norm' and one of these strings:

- 'L2' The Fourier transform of the analyzing wavelet at a given scale is multiplied by the corresponding scale. 'L2' is the default normalization.
- 'L1' The Fourier transform of the analyzing wavelet is multiplied by 1 at all scales.
- 'L0' The Fourier transform of the analyzing wavelet at a given scale is multiplied by the square of the corresponding scale.

```
Example: 'norm', 'L1'

'scales' — Scoles
2^(0:5) (default) | scalar | vector
```

Scales, specified as a comma-separated pair consisting of 'scales' and either a positive real-valued scalar or a vector of positive real numbers.

```
Example: 'scales',2^(1:6)

'wavelet' — Analyzing wavelet

'morl' (default) | string | structure | cell array
```

Analyzing wavelet, specified as a comma-separated pair consisting of 'wavelet' and a string, a structure, or a cell array. CWtftinfo2 provides a comprehensive list of supported wavelets and associated parameters.

If you specify 'wavelet' as a structure, the structure must contain two fields:

- name the string corresponding to a supported wavelet.
- param a cell array with the parameters of the wavelet.

If you specify 'wavelet' as a cell array, wav, the cell array must contain two elements:

- wav{1} the string corresponding to a supported wavelet.
- wav{2} a cell array with the parameters of the wavelet.

```
Example: 'wavelet', {'morl', {6,1,1}}
Example: 'wavelet', struct('name', 'paul', 'param', {'p',2})
```

Output Arguments

```
cwtstruct - 2-D CWT
```

structure

The 2-D CWT, returned as a structure with the following fields:

wav — Analyzing wavelet and parameters

structure

Analyzing wavelet and parameters, returned as a structure with the following fields:

- wname name
- param parameters

wav_norm — Normalization constants

matrix

Normalization constants, returned as a M-by-N matrix where M is the number of scales and N is the number of angles.

cfs — CWT coefficients

array

CWT coefficients, returned as an N-D array. The row and column dimensions of the array equal the row and column dimensions of the input data. The third page of the array is equal to 1 or 3 depending on whether the input data is a grayscale or truecolor image. The fourth page of the array is equal to the number of scales and the fifth page of the array is equal to the number of angles.

scales — Scales

vector

Scales for the 2-D CWT, returned as a row vector.

angles — Angles

vector

Angles for the 2-D CWT, returned as a row vector.

meanSIG - Mean

scalar

Mean of the input data, returned as a scalar

Introduced in R2013b

cwtext

Real or complex continuous 1-D wavelet coefficients using extension parameters

Syntax

```
COEFS = cwtext(S,SCALES,'wname')
COEFS = cwtext(S,SCALES,'wname',PropName1,ProVal1, ...)
EXTMODE = struct('Mode',ModeVAL,'Side',SideVAL,'Len',LenVAL);
EXTMODE = {ModeVAL,SideVAL,LenVAL};
COEFS = cwtext(...,'PlotMode',PLOTMODE)
```

Description

COEFS = cwtext(S,SCALES, 'wname') computes the continuous wavelet coefficients of the vector S at real, positive SCALES, using a wavelet named 'wname'. The signal S is real; the wavelet can be real or complex.

COEFS = cwtext(S,SCALES,'wname',PropName1,ProVal1, ...) computes and plots the continuous wavelet transform coefficients using extra parameters. Valid values for PropName are:

'ExtMode''ExtSide''ExtLen''PlotMode''xlim'

The continuous wavelet transform coefficients are computed using the extension parameters:

- 'ExtMode''ExtSide'
- 'ExtLen'

Valid values for *ExtMode* are:

- 'zpd' (zero padding)
- 'sp0' (smooth extension of order 0)
- 'sp1' (smooth extension of order 1)

etc.

Valid values for ExtSide are:

- ExtSide = 'l' (or 'u') for left (or up) extension
- ExtSide = 'r' (or 'd') for right (or down) extension
- ExtSide = 'b' for extension on both sides
- ExtSide = 'n' null extension

For the complete list of valid values for ExtMode and ExtSide, see wextend.

ExtLen is the length of extension.

Default values for extension parameters are 'zpd' and 'b'. ExtLen is computed using the maximum of SCALES.

Instead of three parameters, use the following syntaxes:

```
EXTMODE = struct('Mode', ModeVAL, 'Side', SideVAL, 'Len', LenVAL);
EXTMODE = {ModeVAL, SideVAL, LenVAL};
```

COEFS = cwtext(..., 'PlotMode', PLOTMODE) computes and plots the continuous wavelet transform coefficients. Coefficients are colored using PLOTMODE:

- PLOTMODE = 'lv1' (By scale)
- PLOTMODE = 'glb' (All scales)
- PLOTMODE = 'abslv1' or 'lvlabs' (Absolute value and By scale)
- PLOTMODE = 'absglb' or 'glbabs' (Absolute value and All scales)

You get 3-D plots (surfaces) using the same keywords listed above for the PLOTMODE parameter, preceded by '3D', for example, PLOTMODE = '3Dlvl'.

When PLOTMODE = 'scal' or 'scalCNT' the continuous wavelet transform coefficients and the corresponding scalogram (percentage of energy for each coefficient) are computed.

When PLOTMODE is 'scal', a scaled image of scalogram is displayed. When PLOTMODE is 'scalCNT', a contour representation of scalogram is displayed.

If the XLIM parameter is given, the continuous wavelet transform coefficients are colored using PLOTMODE and XLIM.

```
XLIM = [x1 \ x2] \ with 1 <= x1 < x2 <= length(S).
```

For each given scale a within the vector SCALES, the wavelet coefficients C(a,b) are computed for b = 1 to ls = length(S), and are stored in COEFS(i,:) if a = SCALES(i).

Output argument COEFS is a la-by-ls matrix where la is the length of SCALES. COEFS is a real or complex matrix depending on the wavelet type.

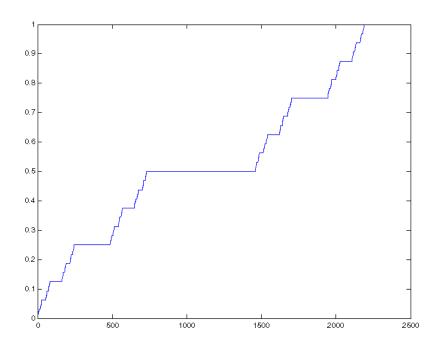

Examples of valid use are as follows:

```
t = linspace(-1,1,512);
s = 1-abs(t);
c = cwtext(s, 1:32, 'cgau4');
c = cwtext(s, [64 32 16:-2:2], 'morl');
c = cwtext(s,[3 18 12.9 7 1.5],'db2');
c = cwtext(s,1:32,'sym2','plotMode','lv1');
c = cwtext(s,1:64,'sym4','plotMode','abslvl','xlim',[100 400]);
[c,Sc] = cwtext(s,1:64,'sym4','plotMode','scal');
[c,Sc] = cwtext(s,1:64,'sym4','plotMode','scalCNT');
[c,Sc] = cwtext(s,1:64,'sym4','plotMode','scalCNT', ...
                                  'extMode', 'sp1');
c = cwtext(s,1:64,'sym4','plotMode','lvl','extMode','sp0');
c = cwtext(s,1:64,'sym4','plotMode','lvl','extMode','sp1');
c = cwtext(s,1:64,'sym4','plotMode','lvl', ...
                            'extMode',{'sp1','b',300});
ext = struct('Mode', 'sp1', 'Side', 'b', 'Len', 300);
c = cwtext(s,1:64,'sym4','plotMode','lvl','extMode',ext);
```

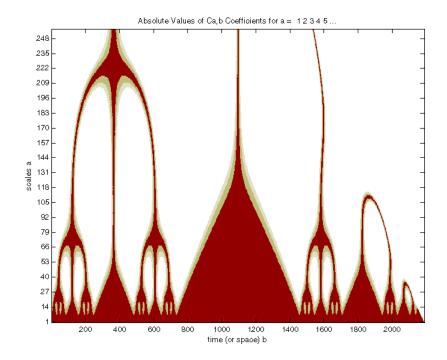

Examples

This example demonstrates the difference between a continuous wavelet transform which deals with signal extension and one which does not.

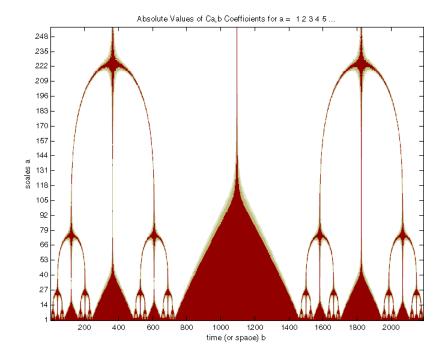

% Load and plot the signal load wcantor plot(wcantor)

% Compute and plot the coefficients
cwt(wcantor,(1:256),'mexh','absglb');
colormap(pink(4))

In this figure above, which is produced by the cwt function, the values of coefficients are tremendously affected by the boundary effect due to the discontinuity of the signal on the right. The default (zero-padding) extension mode on the right explains this important discontinuity because the last value is 1. On the left there is no effect because the first value is 0.

In this figure, produced by the cwtext function, the suitable extension mode of the signal is very efficient, giving as it can be seen, a good result.

Introduced in R2008a

dbaux

Daubechies wavelet filter computation

Syntax

```
W = dbaux(N,SUMW)
W = dbaux(N)
W = dbaux(N,0)
```

Description

W = dbaux(N, SUMW) is the order N Daubechies scaling filter such that sum(W) = SUMW. Possible values for N are 1, 2, 3, ...

Note Instability may occur when N is too large.

```
W = dbaux(N) is equivalent to W = dbaux(N,1)
W = dbaux(N,0) is equivalent to W = dbaux(N,1)
```

Daubechies' Extremal Phase Scaling Filter with Specified Sum

This example shows to determine the Daubechies' extremal phase scaling filter with a specified sum. The two most common values for the sum are $\sqrt{2}$ and 1.

Construct two versions of the 'db4' scaling filter. One scaling filter sums to $\sqrt{2}$ and the other version sums to 1.

```
NumVanishingMoments = 4;
h = dbaux(NumVanishingMoments,sqrt(2));
m0 = dbaux(NumVanishingMoments,1);
```

The filter with sum equal to $\sqrt{2}$ is the synthesis (reconstruction) filter returned by wfilters and used in the discrete wavelet transform.

```
[LoD,HiD,LoR,HiR] = wfilters('db4');
max(abs(LoR-h))
ans =
4.2613e-13
```

For orthogonal wavelets, the analysis (decomposition) filter is the time-reverse of the synthesis filter.

```
max(abs(LoD-fliplr(h)))
ans =
4.2613e-13
```

Limitations

The computation of the dbN Daubechies scaling filter requires the extraction of the roots of a polynomial of order 4N. Instability may occur when N is too large.

More About

Algorithms

The algorithm used is based on a result obtained by Shensa (see "References"), showing a correspondence between the "Lagrange à trous" filters and the convolutional squares of the Daubechies wavelet filters.

The computation of the order N Daubechies scaling filter w proceeds in two steps: compute a "Lagrange à trous" filter P, and extract a square root. More precisely:

• P the associated "Lagrange à trous" filter is a symmetric filter of length 4N-1. P is defined by

$$P = [a(N) \ 0 \ a(N-1) \ 0 \ \dots \ 0 \ a(1) \ 1 \ a(1) \ 0 \ a(2) \ 0 \ \dots \ 0 \ a(N)]$$

· where

$$a(k) = \frac{\prod_{\substack{i = -N+1 \\ i \neq k}}^{N} \left(\frac{1}{2} - i\right)}{\prod_{\substack{i = -N+1 \\ i \neq k}}^{N} (k-i)} \text{ for } k = 1,...,N$$

• Then, if w denotes dbN Daubechies scaling filter of sum $\sqrt{2}$, w is a square root of P:

P = conv(wrev(w), w) where w is a filter of length 2N.

The corresponding polynomial has N zeros located at -1 and N-1 zeros less than 1 in modulus.

Note that other methods can be used; see various solutions of the spectral factorization problem in Strang-Nguyen (p. 157).

ddencmp

Default values for denoising or compression

Syntax

```
[THR,SORH,KEEPAPP,CRIT] = ddencmp(IN1,IN2,X)

[THR,SORH,KEEPAPP] = ddencmp(IN1,'wv',X)

[THR,SORH,KEEPAPP,CRIT] = ddencmp(IN1,'wp',X)
```

Description

ddencmp returns default values for denoising or compression for the critically-sampled discrete wavelet or wavelet packet transform.

You can use ddencmp for 1-D signals or 2-D images.

[THR, SORH, KEEPAPP, CRIT] = ddencmp(IN1, IN2, X) returns default values for denoising or compression, using wavelets or wavelet packets, of an input vector or matrix X, which can be a one- or two-dimensional signal. THR is the threshold, SORH is for soft or hard thresholding, KEEPAPP allows you to keep approximation coefficients, and CRIT (used only for wavelet packets) is the entropy name (see wentropy for more information).

IN1 is 'den' for denoising or 'cmp' for compression.

IN2 is 'wv' for wavelet or 'wp' for wavelet packet.

For wavelets (three output arguments):

[THR, SORH, KEEPAPP] = ddencmp(IN1, 'wv', X) returns default values for denoising (if IN1 = 'den') or compression (if IN1 = 'cmp') of X. These values can be used for wdencmp.

For wavelet packets (four output arguments):

[THR, SORH, KEEPAPP, CRIT] = ddencmp(IN1, 'wp', X) returns default values for denoising (if IN1 = 'den') or compression (if IN1 = 'cmp') of X. These values can be used for wdencmp.

Examples

Default Global Threshold for Wavelet Denoising

Determine the default global denoising threshold for an N(0,1) white noise input.

Create an N(0,1) white noise input. Set the random number generator to the default initial settings for reproducible results.

```
dwtmode('per');
rng default;
x = randn(512,1);
```

Use ddencmp to obtain the default global threshold for wavelet denoising. Demonstrate that the threshold is equal to the universal threshold of Donoho and Johnstone scaled by a robust estimate of the variance.

```
[thr,sorh,keepapp] = ddencmp('den','wv',x);
[A,D] = dwt(x,'db1');
noiselev = median(abs(D))/0.6745;
thresh = sqrt(2*log(length(x)))*noiselev;
```

Compare the value of the variable thr to the value of thresh.

Default Global Threshold for Wavelet Packet Compression

Determine the default global compression threshold for an N(0,1) white noise input.

Create an N(0,1) white noise input. Set the random number generator to the default initial settings for reproducible results.

```
dwtmode('per');
rng default;
x = randn(512,1);
```

Use ddencmp with the 'cmp' and 'wp' input arguments to return the default global compression threshold for a wavelet packet transform.

```
[thr,sorh,keepapp,crit] = ddencmp('den','wp',x);
```

Introduced before R2006a

dddtree

Dual-tree and double-density 1-D wavelet transform

Syntax

```
wt = dddtree(typetree,x,level,fdf,df)
wt = dddtree(typetree,x,level,fname)
wt = dddtree(typetree,x,level,fname1,fname2)
```

Description

wt = dddtree(typetree,x,level,fdf,df) returns the typetree discrete wavelet transform (DWT) of the 1-D input signal, x, down to level, level. The wavelet transform uses the decomposition (analysis) filters, fdf, for the first level and the analysis filters, df, for subsequent levels. Supported wavelet transforms are the critically sampled DWT, double-density, dual-tree complex, and dual-tree double-density complex wavelet transform. The critically sampled DWT is a filter bank decomposition in an orthogonal or biorthogonal basis (nonredundant). The other wavelet transforms are oversampled filter banks.

wt = dddtree(typetree,x,level,fname) uses the filters specified by fname to obtain the wavelet transform. Valid filter specifications depend on the type of wavelet transform. See dtfilters for details.

wt = dddtree(typetree,x,level,fname1,fname2) uses the filters specified in fname1 for the first stage of the dual-tree wavelet transform and the filters specified in fname2 for subsequent stages of the dual-tree wavelet transform. Specifying different filters for stage 1 is valid and necessary only when typetree is 'cplxdt' or 'cplxdddt'.

Examples

Complex Dual-Tree Wavelet Transform

Obtain the complex dual-tree wavelet transform of the noisy Doppler signal. The FIR filters in the first and subsequent stages result in an approximately analytic wavelet as required.

Create the first-stage analysis filters for the two trees.

    0.0352
                    0];
```

Load the noisy Doppler signal and obtain the complex dual-tree wavelet transform down to level 4.

```
load noisdopp;
wt = dddtree('cplxdt',noisdopp,4,Faf,af);
```

Plot an approximation based on the level-four approximation coefficients.

```
xapp = dddtreecfs('r',wt,'scale',{5});
plot(noisdopp); hold on;
plot(cell2mat(xapp),'r','linewidth',3);
axis tight;
```

Double-Density Wavelet Transform

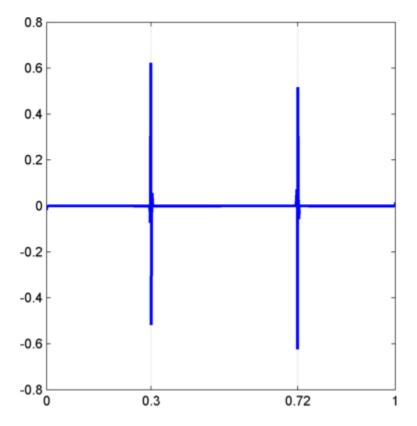

Obtain the double-density wavelet transform of a signal with two discontinuities. Use the level-one detail coefficients to localize the discontinuities.

Create a signal consisting of a 2-Hz sine wave with a duration of 1 second. The sine wave has discontinuities at 0.3 and 0.72 seconds.

```
N = 1024;
t = linspace(0,1,1024);
x = 4*sin(4*pi*t);
x = x - sign(t - .3) - sign(.72 - t);
plot(t,x); xlabel('t'); ylabel('x');
title('Original Signal');
```

Obtain the double-density wavelet transform of the signal, reconstruct an approximation based on the level-one detail coefficients, and plot the result.

```
wt = dddtree('ddt',x,1,'filters1');
wt.cfs{2} = zeros(1,512);
xrec = idddtree(wt);
plot(t,xrec,'linewidth',2)
set(gca,'xtick',[0 0.3 0.72 1]); set(gca,'xgrid','on');
```

First-Level Detail Coefficients Approximation — Complex Dual-Tree

Obtain the complex dual-tree wavelet transform of a signal with two discontinuities. Use the first-level detail coefficients to localize the discontinuities.

Create a signal consisting of a 2-Hz sine wave with a duration of 1 second. The sine wave has discontinuities at 0.3 and 0.72 seconds.

```
N = 1024;
```

```
t = linspace(0,1,1024);
x = 4*sin(4*pi*t);
x = x - sign(t - .3) - sign(.72 - t);
plot(t,x); xlabel('t'); ylabel('x');
title('Original Signal');
```

Obtain the dual-tree wavelet transform of the signal, reconstruct an approximation based on the level-one detail coefficients, and plot the result.

```
wt = dddtree('cplxdt',x,1,'FSfarras','qshift06');
wt.cfs{2} = zeros(1,512,2);
xrec = idddtree(wt);
plot(t,xrec,'linewidth',2)
set(gca,'xtick',[0 0.3 0.72 1]); set(gca,'xgrid','on');
```

"Analytic Wavelets Using the Dual-Tree Wavelet Transform"

Input Arguments

typetree — Type of wavelet decomposition 'dwt' | 'ddt' | 'cplxdt' | 'cplxdddt'

Type of wavelet decomposition, specified as one of 'dwt', 'ddt', 'cplxdt', or 'cplxddt'. The type, 'dwt', gives a critically sampled (nonredundant) discrete wavelet transform. The other decomposition types produce oversampled wavelet transforms. 'ddt' produces a double-density wavelet transform. 'cplxdt' produces a dual-tree complex wavelet transform. 'cplxdddt' produces a double-density dual-tree complex wavelet transform.

x — Input signal

vector

Input signal, specified as an even-length row or column vector. If L is the value of the level of the wavelet decomposition, 2^L must divide the length of x. Additionally, the length of the signal must be greater than or equal to the product of the maximum length of the decomposition (analysis) filters and $2^{(L-1)}$.

Data Types: double

1evel - Level of wavelet decomposition

positive integer

Level of the wavelet decomposition, specified as an integer. If L is the value of ${\tt level}$, 2^L must divide the length of x . Additionally, the length of the signal must be greater than or equal to the product of the maximum length of the decomposition (analysis) filters and $2^{(L-1)}$.

Data Types: double

fdf — Level-one analysis filters

matrix | cell array

The level-one analysis filters, specified as a matrix or cell array of matrices. Specify fdf as a matrix when typetree is 'dwt' or 'ddt'. The size and structure of the matrix depend on the typetree input as follows:

- 'dwt' This is the critically sampled discrete wavelet transform. In this case, fdf is a two-column matrix with the lowpass (scaling) filter in the first column and the highpass (wavelet) filter in the second column.
- 'ddt' This is the double-density wavelet transform. The double-density DWT is a three-channel perfect reconstruction filter bank. fdf is a three-column matrix with the lowpass (scaling) filter in the first column and the two highpass (wavelet) filters in the second and third columns. In the double-density wavelet transform, the single lowpass and two highpass filters constitute a three-channel perfect reconstruction filter bank. This is equivalent to the three filters forming a tight frame. You cannot arbitrarily choose the two wavelet filters in the double-density DWT. The three filters together must form a tight frame.

Specify fdf as a 1-by-2 cell array of matrices when typetree is a dual-tree transform, 'cplxdt' or 'cplxdddt'. The size and structure of the matrix elements depend on the typetree input as follows:

- For the dual-tree complex wavelet transform, 'cplxdt', fdf{1} is a two-column matrix containing the lowpass (scaling) filter and highpass (wavelet) filters for the first tree. The scaling filter is the first column and the wavelet filter is the second column. fdf{2} is a two-column matrix containing the lowpass (scaling) and highpass (wavelet) filters for the second tree. The scaling filter is the first column and the wavelet filter is the second column.
- For the double-density dual-tree complex wavelet transform, 'cplxdddt', fdf{1} is a three-column matrix containing the lowpass (scaling) and two highpass (wavelet) filters for the first tree and fdf{2} is a three-column matrix containing the lowpass (scaling) and two highpass (wavelet) filters for the second tree.

Data Types: double

df — Analysis filters for levels > 1

matrix | cell array

Analysis filters for levels > 1, specified as a matrix or cell array of matrices. Specify df as a matrix when typetree is 'dwt' or 'ddt'. The size and structure of the matrix depend on the typetree input as follows:

- 'dwt' This is the critically sampled discrete wavelet transform. In this case, df
 is a two-column matrix with the lowpass (scaling) filter in the first column and the
 highpass (wavelet) filter in the second column. For the critically sampled orthogonal
 or biorthogonal DWT, the filters in df and fdf must be identical.
- 'ddt' This is the double-density wavelet transform. The double-density DWT is a three-channel perfect reconstruction filter bank. df is a three-column matrix with the lowpass (scaling) filter in the first column and the two highpass (wavelet) filters in the second and third columns. In the double-density wavelet transform, the single lowpass and two highpass filters must constitute a three-channel perfect reconstruction filter bank. This is equivalent to the three filters forming a tight frame. For the double-density DWT, the filters in df and fdf must be identical.

Specify df as a 1-by-2 cell array of matrices when typetree is a dual-tree transform, 'cplxdt' or 'cplxdddt'. For dual-tree transforms, the filters in fdf and df must be different. The size and structure of the matrix elements in the cell array depend on the typetree input as follows:

- For the dual-tree complex wavelet transform, 'cplxdt', df{1} is a two-column matrix containing the lowpass (scaling) and highpass (wavelet) filters for the first tree. The scaling filter is the first column and the wavelet filter is the second column. df{2} is a two-column matrix containing the lowpass (scaling) and highpass (wavelet) filters for the second tree. The scaling filter is the first column and the wavelet filter is the second column.
- For the double-density dual-tree complex wavelet transform, 'cplxdddt', df{1} is a three-column matrix containing the lowpass (scaling) and two highpass (wavelet) filters for the first tree and df{2} is a three-column matrix containing the lowpass (scaling) and two highpass (wavelet) filters for the second tree.

Data Types: double

fname - Filter name

string

Filter name, specified as a string. For the critically sampled DWT, specify any valid orthogonal or biorthogonal wavelet filter. See wfilters for details. For the doubledensity wavelet transform, 'ddt', valid choices are 'filters1' and 'filters2'. For the complex dual-tree wavelet transform, valid choices are 'dtfP' with P=1, 2, 3, 4. For the double-density dual-tree wavelet transform, the only valid choice is 'dddtf1'. See dtfilters for more details on valid filter strings for the oversampled wavelet filter banks.

Data Types: char

fname1 — First-stage filter name

string

First-stage filter name, specified as a string. Specifying a different filter for the first stage is valid and necessary only in the dual-tree transforms, 'cplxdt' and 'cplxddt'. In the complex dual-tree wavelet transform, you can use any valid wavelet filter for the first stage. In the double-density dual-tree wavelet transform, the first-stage filters must form a three-channel perfect reconstruction filter bank.

Data Types: char

fname2 — Filter name for stages > 1

string

Filter name for stages > 1, specified as a string. You must specify a first-level filter that is different from the wavelet and scaling filters in subsequent levels when using the dual-tree wavelet transforms, 'cplxdt' or 'cplxdddt'. See dtfilters for valid choices.

Data Types: char

Output Arguments

wt — Wavelet transform

structure

Wavelet transform, returned as a structure with these fields:

type — Type of wavelet decomposition (filter bank)

```
'dwt' | 'ddt' | 'cplxdt' | 'cplxdddt'
```

Type of wavelet decomposition (filter bank) used in the analysis, returned as one of 'dwt', 'ddt', 'cplxdt', or 'cplxdddt'. The type, 'dwt', gives a critically

sampled discrete wavelet transform. The other types correspond to oversampled wavelet transforms. 'ddt' is a double-density wavelet transform, 'cplxdt' is a dual-tree complex wavelet transform, and 'cplxdddt' is a double-density dual-tree complex wavelet transform.

1evel — Level of the wavelet decomposition

positive integer

Level of wavelet decomposition, returned as a positive integer.

filters — Decomposition (analysis) and reconstruction (synthesis) filters

structure

Decomposition (analysis) and reconstruction (synthesis) filters, returned as a structure with these fields:

Fdf — First-stage analysis filters

matrix | cell array

First-stage analysis filters, returned as an *N*-by-2 or *N*-by-3 matrix for single-tree wavelet transforms, or a cell array of two *N*-by-2 or *N*-by-3 matrices for dual-tree wavelet transforms. The matrices are *N*-by-3 for the double-density wavelet transforms. For an *N*-by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an *N*-by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the first-stage analysis filters for the corresponding tree.

Df — Analysis filters for levels > 1

matrix | cell array

Analysis filters for levels > 1, returned as an N-by-2 or N-by-3 matrix for single-tree wavelet transforms, or a cell array of two N-by-2 or N-by-3 matrices for dual-tree wavelet transforms. The matrices are N-by-3 for the double-density wavelet transforms. For an N-by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N-by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the analysis filters for the corresponding tree.

Frf — First-level reconstruction filters

matrix | cell array

First-level reconstruction filters, returned as an *N*-by-2 or *N*-by-3 matrix for single-tree wavelet transforms, or a cell array of two *N*-by-2 or *N*-by-3 matrices for dual-tree wavelet transforms. The matrices are *N*-by-3 for the double-density wavelet transforms. For an *N*-by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an *N*-by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the first-stage synthesis filters for the corresponding tree.

Rf — Reconstruction filters for levels > 1

matrix | cell array

Reconstruction filters for levels > 1, returned as an N-by-2 or N-by-3 matrix for single-tree wavelet transforms, or a cell array of two N-by-2 or N-by-3 matrices for dual-tree wavelet transforms. The matrices are N-by-3 for the double-density wavelet transforms. For an N-by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N-by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the synthesis filters for the corresponding tree.

cfs — Wavelet transform coefficients

cell array of matrices

Wavelet transform coefficients, returned as a 1-by-(level+1) cell array of matrices. The size and structure of the matrix elements of the cell array depend on the type of wavelet transform, typetree, as follows:

- 'dwt' cfs{j}
 - j = 1,2,... level is the level.
 - $cfs{level+1}$ are the lowpass, or scaling, coefficients.
- 'ddt' cfs{j}(:,:,k)
 - j = 1,2,... level is the level.
 - k = 1,2 is the wavelet filter.
 - cfs{level+1}(:,:) are the lowpass, or scaling, coefficients.
- 'cplxdt' cfs{j}(:,:,m)
 - j = 1,2,... level is the level.

- m = 1,2 are the real and imaginary parts.
- cfs{level+1}(:,:) are the lowpass, or scaling, coefficients.
- 'cplxdddt' cfs{j}(:,:,k,m)
 - j = 1,2,... level is the level.
 - k = 1,2 is the wavelet filter.
 - m = 1,2 are the real and imaginary parts.
 - $cfs{level+1}(:,:)$ are the lowpass, or scaling, coefficients.

dddtree2 | dddtreecfs | dtfilters | idddtree

Introduced in R2013b

dddtreecfs

Extract dual-tree/double-density wavelet coefficients or projections

Syntax

```
out = dddtreecfs(outputtype,wt,outputspec,outputindices)
out = dddtreecfs(outputtype,wt,outputspec,outputindices,'plot')
```

Description

out = dddtreecfs(outputtype,wt,outputspec,outputindices) extracts the coefficients or subspace projections from the 1-D or 2-D wavelet decomposition, wt. If outputtype equals 'e', out contains wavelet or scaling coefficients. If outputtype equals 'r', out contains wavelet or scaling subspace projections (reconstructions).

out = dddtreecfs(outputtype,wt,outputspec,outputindices,'plot') plots the signal or image reconstruction or specified analysis coefficients. You can include the 'plot' option anywhere after the Wt input.

Examples

Reconstruction from 1-D Complex Dual-Tree Wavelet Transform

Obtain the complex dual-tree wavelet transform of the 1-D noisy Doppler signal. Reconstruct an approximation based on the level-three detail coefficients

Load the noisy Doppler signal. Obtain the complex dual-tree transform down to level 3.

```
load noisdopp;
wt = dddtree('cplxdt',noisdopp,3,'dtf1');
```

Plot a reconstruction of the original signal based on the level-three detail coefficients

```
xr = dddtreecfs('r',wt,'scale',{3},'plot');
```

Coefficients from 1-D Complex Dual-Tree Wavelet Transform

Load the noisy Doppler signal. Obtain the complex dual-tree transform down to level 3.

```
load noisdopp;
wt = dddtree('cplxdt',noisdopp,3,'dtf1');
```

Create a cell array of vectors to obtain the second- and third-level detail coefficients from each of the wavelet filter bank trees.

```
outputindices = {[2 1]; [2 2]; [3 1]; [3 2]};
```

The first element of each vector in the cell array denotes the level, or stage. The second element denotes the tree.

Extract the detail coefficients.

```
out = dddtreecfs('e',wt,'ind',outputindices);
```

out is a 1-by-4 cell array. The cell array elements contain the wavelet coefficients corresponding to the elements in outputindices. For example, out{1} contains the level-two detail coefficients from the first tree.

1-D Complex Dual-Tree Wavelet Transform Structure

Load the noisy Doppler signal. Obtain the complex dual-tree transform down to level 3.

```
load noisdopp;
wt = dddtree('cplxdt',noisdopp,3,'dtf1');
```

Create a cell array of vectors to obtain the second- and third-level detail coefficients from each of the wavelet filter bank trees.

```
outputindices = {[2 1]; [2 2]; [3 1];[3 2]};
```

The first element of each vector in the cell array denotes the level, or stage. The second element denotes the tree.

Create a structure array identical to the wt output of dddtree with all the coefficients equal to zero except the first- and second-level detail coefficients.

```
out = dddtreecfs('e',wt,'cumind',outputindices);
```

Extract Diagonal Features from Image

Use the complex dual-tree wavelet transform to isolate diagonal features in an image at +45 and -45 degrees.

Load and display the xbox image.

```
load xbox;
imagesc(xbox)
```

Obtain the complex dual-tree wavelet transform down to level 3.

```
fdf = dtfilters('FSfarras');
df = dtfilters('qshift10');
wt = dddtree2('cplxdt',xbox,3,fdf,df);
```

Isolate the +45 and -45 diagonal image features in the level-one wavelet coefficients. Plot the result.

```
out = dddtreecfs('e',wt,'ind',{[1 3 1 2]; [1 3 2 2]},'plot');
```

Input Arguments

```
outputtype — Output type
```

Output type, specified as 'e' or 'r'. Use 'e' to obtain the scaling or wavelet coefficients. Use 'r' to obtain a projection, or reconstruction, onto the appropriate scaling or wavelet subspace.

wt — Wavelet transform

structure

Wavelet transform, specified as a structure. The structure array is the output of dddtree or dddtree2.

```
outputspec — Output specification
```

```
'lowpass' | 'scale' | 'ind' | 'cumind'
```

Output specification, specified as one of 'lowpass', 'scale', 'ind', or 'cumind'. The output specifications are defined as follows:

• 'lowpass' — Outputs the lowpass, or scaling, coefficients or a signal/image approximation based on the scaling coefficients. If you set the output specification to 'lowpass', do not specify outputindices. If the outputtype is 'e', out is a structure array with fields identical to the input structure array wt except that all wavelet (detail) coefficients are equal to zero. If the outputtype is 'r', out is a signal or image approximation based on the scaling coefficients. The signal or image approximation is equal in size to the original input to dddtree or dddtree2.

- 'scale' Outputs the coefficients or a signal/image approximation based on the scales specified in outputindices. If the outputtype is 'e', out is a cell array of structure arrays. The fields of the structure arrays in out are identical to the fields of the input structure array wt. The coefficients in the cfs field are all equal to zero except the coefficients corresponding to the scales in outputindices. If the outputtype is 'r', out is a signal or image approximation based on the scales in outputindices. The signal or image approximation is equal in size to the original input to dddtree or dddtree2.
- 'ind' Outputs the coefficients or a signal/image approximation based on the tree-position indices specified in outputindices. If the outputtype is 'e', out is a cell array of vectors or matrices containing the coefficients specified by the tree-position indices in outputindices. If the outputtype is 'r', out is a cell array of vectors or matrices containing signal or image approximations based on the corresponding tree-position indices in outputindices.
- 'cumind' Outputs the coefficients or a signal/image approximation based on the tree-position indices specified in Outputindices. If the Outputtype is 'e', Out is a structure array. The fields of the structure array are identical to the fields of the input structure array Wt. The coefficients in the cfs field are all equal to zero except the coefficients corresponding to the tree positions in Outputindices. If the Outputtype is 'r', Out is a signal or image approximation based on the coefficients corresponding to the tree-position indices in Outputindices.

```
Example: 'ind', {[1 1]; [1 2]}
```

outputindices — Output indices

cell array

Output indices, specified as a cell array with scalar or vector elements. If outputspec equals 'scale', a scalar element selects the corresponding element in the cfs field of wt. If outputspec equals 'ind' or 'cumind', the elements of outputspec are row vectors. The first element of the row vector corresponds to the element in the cfs field of wt. Subsequent elements in the row vector correspond to the indices of the array contained in the cell array element.

```
Example: 'scale', {1;2;3}
```

Output Arguments

out — Signal or image reconstruction or coefficients

cell array | structure | vector | matrix

Signal or image reconstruction or coefficients, returned as a vector, matrix, structure array, cell array of vectors or matrices, or cell array of structure arrays. The form of out depends on the value of outputspec and outputindices.

dddtree | dddtree2 | plotdt

Introduced in R2013b

dddtree2

Dual-tree and double-density 2-D wavelet transform

Syntax

```
wt = dddtree2(typetree,x,level,fdf,df)
wt = dddtree2(typetree,x,level,fname)
wt = dddtree2(typetree,x,level,fname1,fname2)
```

Description

wt = dddtree2(typetree,x,level,fdf,df) returns the typetree discrete wavelet transform of the 2-D input image, x, down to level, level. The wavelet transform uses the decomposition (analysis) filters, fdf, for the first level and the analysis filters, df, for subsequent levels. Supported wavelet transforms are the critically sampled DWT, double-density, real oriented dual-tree, complex oriented dual-tree, real oriented dual-tree double-density, and complex oriented dual-tree double-density wavelet transform. The critically sampled DWT is a filter bank decomposition in an orthogonal or biorthogonal basis (nonredundant). The other wavelet transforms are oversampled filter banks with differing degrees of directional selectivity.

wt = dddtree2(typetree,x,level,fname) uses the filters specified by fname to obtain the wavelet transform. Valid filter specifications depend on the type of wavelet transform. See dtfilters for details.

wt = dddtree2(typetree,x,level,fname1,fname2) uses the filters specified in fname1 for the first stage of the dual-tree wavelet transform and the filters specified in fname2 for subsequent stages of the dual-tree wavelet transform. Specifying different filters for stage 1 is valid and necessary only when typetree is 'realdt', 'cplxdt', 'realdddt', or 'cplxddt'.

Examples

Real Oriented Dual-Tree Wavelets

Visualize the six directional wavelets of the real oriented dual-tree wavelet transform.

Create the first-stage analysis filters for the two trees.

```
Faf\{1\} = [0]

Real Oriented Dual-Tree Wavelets

Double-Density Wavelet Transform

Obtain the double-density wavelet transform of an image.

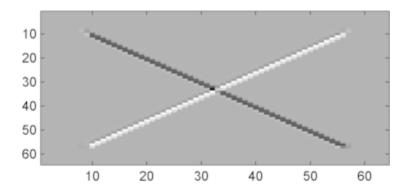

Load the image and obtain the double-density wavelet transform. \\

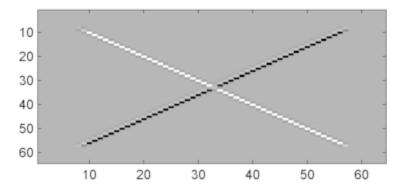

```
load xbox;
imagesc(xbox); colormap gray;
wt = dddtree2('ddt',xbox,1,'filters1');
```

Visualize the diagonal details in the two wavelet HH subbands.

```
HH1 = wt.cfs{1}(:,:,5);
HH2 = wt.cfs{1}(:,:,8);
subplot(211)
imagesc(HH1);
colormap gray;
subplot(212);
imagesc(HH2);
```

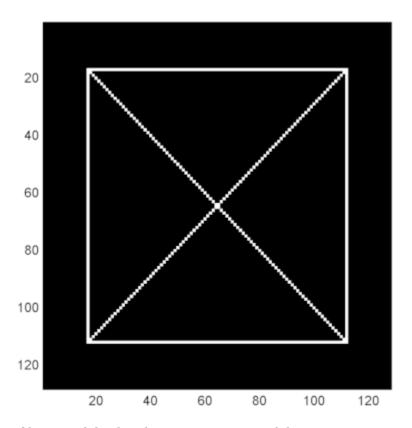

Complex Dual-Tree Wavelet Transform

Obtain the complex dual-tree wavelet transform of an image. Show that the complex dual-tree wavelet transform can detect the two different diagonal directions.

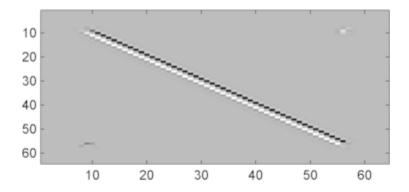

Load the image and obtain the complex dual-tree wavelet transform.

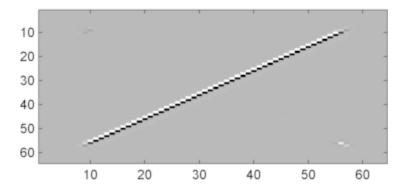

```
load xbox;
imagesc(xbox); colormap gray;
wt = dddtree2('cplxdt',xbox,1,'FSfarras','qshift10');
```

Obtain and display the imaginary parts of the 2 trees.

```
waveletcfs = wt.cfs{1};
subplot(211)
imagesc(waveletcfs(:,:,3,1,2));
colormap gray;
subplot(212)

"Analytic Wavelets Using the Dual-Tree Wavelet Transform"

Input Arguments

typetree — Type of wavelet decomposition

'dwt' | 'ddt' | 'realdt' | 'cplxdt' | 'realdddt' | 'cplxdddt'

Type of wavelet decomposition, specified as one of 'dwt', 'ddt', 'realdt', 'cplxdt', 'realdddt', or 'cplxdddt'. The type, 'dwt', produces a critically sampled (nonredundant) discrete wavelet transform. The other decomposition types produce oversampled wavelet transforms. 'ddt' produces a double-density wavelet transform with one scaling and two wavelet filters for both row and column filtering. The double-density wavelet transform uses the same filters at all stages. 'realdt' and 'cplxdt' produce oriented dual-tree wavelet transforms consisting of two and four separable

wavelet transforms. 'realdddt' and 'cplxdddt' produce double-density dual-tree wavelet transforms. The dual-tree wavelet transforms use different filters for the first stage (level).

x - Input image

matrix

Input image, specified as a matrix with even-length row and column dimensions. Both the row and column dimensions must be divisible by 2^L , where L is the level of the wavelet transform. Additionally, the minimum of the row and column dimensions of the image must be greater than or equal to the product of the maximum length of the decomposition (analysis) filters and $2^{(L-I)}$.

Data Types: double

1evel — Level of wavelet decomposition

integer

Level of the wavelet decomposition, specified as a positive integer. If L is the value of level, 2^L must divide both the row and column dimensions of x. Additionally, the minimum of the row and column dimensions of the image must be greater than or equal to the product of the maximum length of the decomposition (analysis) filters and $2^{(L-1)}$.

fdf — Level-one analysis filters

matrix | cell array

The level-one analysis filters, specified as a matrix or cell array of matrices. Specify fdf as a matrix when typetree is 'dwt' or 'ddt'. The size and structure of the matrix depend on the typetree input as follows:

- 'dwt' This is the critically sampled discrete wavelet transform. In this case, fdf is a two-column matrix with the lowpass (scaling) filter in the first column and the highpass (wavelet) filter in the second column.
- 'ddt' This is the double-density wavelet transform. The double-density DWT is a three-channel perfect reconstruction filter bank. fdf is a three-column matrix with the lowpass (scaling) filter in the first column and the two highpass (wavelet) filters in the second and third columns. In the double-density wavelet transform, the single lowpass and two highpass filters constitute a three-channel perfect reconstruction filter bank. This is equivalent to the three filters forming a tight frame. You cannot arbitrarily choose the two wavelet filters in the double-density DWT. The three filters together must form a tight frame.

Specify fdf as a 1-by-2 cell array of matrices when typetree is a dual-tree transform, 'realdt', 'cplxdt', 'realdddt', or 'cplxdddt'. The size and structure of the matrix elements in the cell array depend on the typetree input as follows:

- For the dual-tree complex wavelet transforms, 'realdt' and 'cplxdt', fdf{1} is an *N*-by-2 matrix containing the lowpass (scaling) and highpass (wavelet) filters for the first tree and fdf{2} is an *N*-by-2 matrix containing the lowpass (scaling) and highpass (wavelet) filters for the second tree.
- For the double-density dual-tree complex wavelet transforms, 'realdddt' and 'cplxdddt', fdf{1} is an *N*-by-3 matrix containing the lowpass (scaling) and two highpass (wavelet) filters for the first tree and fdf{2} is an *N*-by-3 matrix containing the lowpass (scaling) and two highpass (wavelet) filters for the second tree.

df — Analysis filters for levels > 1

matrix | cell array

Analysis filters for levels > 1, specified as a matrix or cell array of matrices. Specify df as a matrix when typetree is 'dwt' or 'ddt'. The size and structure of the matrix depend on the typetree input as follows:

- 'dwt' This is the critically sampled discrete wavelet transform. In this case, df
 is a two-column matrix with the lowpass (scaling) filter in the first column and the
 highpass (wavelet) filter in the second column. For the critically sampled orthogonal
 or biorthogonal DWT, the filters in df and fdf must be identical.
- 'ddt' This is the double-density wavelet transform. The double-density DWT is a three-channel perfect reconstruction filter bank. df is a three-column matrix with the lowpass (scaling) filter in the first column and the two highpass (wavelet) filters in the second and third columns. In the double-density wavelet transform, the single lowpass and two highpass filters constitute a three-channel perfect reconstruction filter bank. This is equivalent to the three filters forming a tight frame. For the double-density DWT, the filters in df and fdf must be identical.

Specify df as a 1-by-2 cell array of matrices when typetree is a dual-tree transform, 'realdt', 'cplxdt', 'realdddt', or 'cplxdddt'. For dual-tree transforms, the filters in fdf and df must be different. The size and structure of the matrix elements in the cell array depend on the typetree input as follows:

• For the dual-tree wavelet transforms, 'realdt' and 'cplxdt', df{1} is an N-by-2 matrix containing the lowpass (scaling) and highpass (wavelet) filters for the first tree and df{2} is an N-by-2 matrix containing the lowpass (scaling) and highpass (wavelet) filters for the second tree.

• For the double-density dual-tree complex wavelet transforms, 'realdddt' and 'cplxdddt', df{1} is an *N*-by-3 matrix containing the lowpass (scaling) and two highpass (wavelet) filters for the first tree and df{2} is an *N*-by-3 matrix containing the lowpass (scaling) and two highpass (wavelet) filters for the second tree.

fname — Filter name

string

Filter name, specified as a string. For the critically sampled DWT, specify any valid orthogonal or biorthogonal wavelet filter. See wfilters for details. For the redundant wavelet transforms, see dtfilters for valid filter names.

fname1 — First-stage filter name

string

First-stage filter name, specified as a string. Specifying a first-level filter that is different from the wavelet and scaling filters in subsequent levels is valid and necessary only with the dual-tree wavelet transforms, 'realdt', 'cplxdt', 'realdddt', and 'cplxdddt'.

fname2 — Filter name for stages > 1

string

Filter name for stages > 1, specified as a string. Specifying a different filter for stages > 1 is valid and necessary only with the dual-tree wavelet transforms, 'realdt', 'cplxdt', 'realdddt', and 'cplxdddt'.

Output Arguments

wt — Wavelet transform

structure

Wavelet transform, returned as a structure with these fields:

type — Type of wavelet decomposition (filter bank)

```
'dwt'|'ddt'|'realdt'|'cplxdt'|'realdddt'|'cplxdddt'
```

Type of wavelet decomposition used in the analysis returned as one of 'dwt', 'ddt', 'realdt', 'cplxdt', 'realdddt', or 'cplxdddt'. 'dwt' is the critically sampled DWT. 'ddt' produces a double-density wavelet transform with one scaling and two wavelet filters for both row and column filtering. 'realdt' and 'cplxdt'

produce oriented dual-tree wavelet transforms consisting of 2 and 4 separable wavelet transforms. 'realdddt' and 'cplxdddt' produce double-density dual-tree wavelet transforms consisting of two and four separable wavelet transforms.

1evel - Level of wavelet decomposition

positive integer

Level of wavelet decomposition, returned as a positive integer.

filters — Decomposition (analysis) and reconstruction (synthesis) filters

structure

Decomposition (analysis) and reconstruction (synthesis) filters, returned as a structure with these fields:

Fdf — First-stage analysis filters

matrix | cell array

First-stage analysis filters, returned as an N-by-2 or N-by-3 matrix for single-tree wavelet transforms, or a 1-by-2 cell array of two N-by-2 or N-by-3 matrices for dual-tree wavelet transforms. The matrices are N-by-3 for the double-density wavelet transforms. For an N-by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N-by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the first-stage analysis filters for the corresponding tree.

Df — Analysis filters for levels > 1

matrix | cell array

Analysis filters for levels > 1, returned as an N-by-2 or N-by-3 matrix for single-tree wavelet transforms, or a 1-by-2 cell array of two N-by-2 or N-by-3 matrices for dual-tree wavelet transforms. The matrices are N-by-3 for the double-density wavelet transforms. For an N-by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N-by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the analysis filters for the corresponding tree.

Frf — First-level reconstruction filters

matrix | cell array

First-level reconstruction filters, returned as an *N*-by-2 or *N*-by-3 matrix for single-tree wavelet transforms, or a 1-by-2 cell array of two *N*-by-2 or *N*-by-3 matrices for dual-tree wavelet transforms. The matrices are *N*-by-3 for the double-density wavelet transforms. For an *N*-by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an *N*-by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the first-stage synthesis filters for the corresponding tree.

Rf — Reconstruction filters for levels > 1

matrix | cell array

Reconstruction filters for levels > 1, returned as an N-by-2 or N-by-3 matrix for single-tree wavelet transforms, or a 1-by-2 cell array of two N-by-2 or N-by-3 matrices for dual-tree wavelet transforms. The matrices are N-by-3 for the double-density wavelet transforms. For an N-by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N-by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the first-stage analysis filters for the corresponding tree.

cfs — Wavelet transform coefficients

cell array of matrices

Wavelet transform coefficients, specified as a 1-by-(level+1) cell array of matrices. The size and structure of the matrix elements of the cell array depend on the type of wavelet transform, typetree as follows:

- 'dwt' cfs{j}(:,:,d)
 - j = 1,2,... level is the level.
 - d = 1,2,3 is the orientation.
 - cfs{level+1}(:,:) are the lowpass, or scaling, coefficients.
- 'ddt' cfs{j}(:,:,d)
 - j = 1,2,... level is the level.
 - d = 1,2,3,4,5,6,7,8 is the orientation.
 - $cfs{level+1}(:,:)$ are the lowpass, or scaling, coefficients.
- 'realddt' cfs{j}(:,:,d,k)

- j = 1,2,... level is the level.
- d = 1,2,3 is the orientation.
- k = 1,2 is the wavelet transform tree.
- cfs{level+1}(:,:) are the lowpass, or scaling, coefficients.
- 'cplxdt' cfs{j}(:,:,d,k,m)
 - j = 1,2,... level is the level.
 - d = 1,2,3 is the orientation.
 - k = 1,2 is the wavelet transform tree.
 - m = 1,2 are the real and imaginary parts.
 - cfs{level+1}(:,:) are the lowpass, or scaling, coefficients.
- 'realdddt' cfs{j}(:,:,d,k)
 - j = 1,2,... level is the level.
 - d = 1,2,3 is the orientation.
 - k = 1,2 is the wavelet transform tree.
 - cfs{level+1}(:,:) are the lowpass, or scaling, coefficients.
- 'cplxdddt' cfs{j}(:,:,d,k,m)
 - j = 1,2,... level is the level.
 - d = 1,2,3 is the orientation.
 - k = 1.2 is the wavelet transform tree.
 - m = 1.2 are the real and imaginary parts.
 - cfs{level+1}(:,:) are the lowpass, or scaling, coefficients.

depo2ind

Node depth-position to node index

Syntax

Description

depo2ind is a tree-management utility.

For a tree of order ORD, N = depo2ind(ORD, [D P]) computes the indices N of the nodes whose depths and positions are encoded within [D, P].

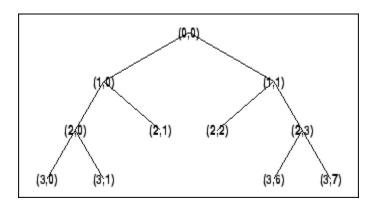

The nodes are numbered from left to right and from top to bottom. The root index is 0.

D and P are column vectors. The values of depths D and positions P must be such that $D \ge 0$ and $0 \le P \le ORD^{D-1}$.

Output indices N are such that $0 \le N < (ORD^{max(D)}-1)/ORD-1$.

Note that for a column vector X, we have depo2ind(0,X) = X.

Examples

```
aln_depo =

detcoef

1-D detail coefficients

Syntax

```
D = detcoef(C,L,N)
D = detcoef(C,L)
```

Description

detcoef is a one-dimensional wavelet analysis function.

D = detcoef(C, L, N) extracts the detail coefficients at level N from the wavelet decomposition structure [C, L]. See wavedec for more information on C and L.

Level N must be an integer such that $1 \le N \le NMAX$ where NMAX = length(L)-2.

D = detcoef(C, L) extracts the detail coefficients at last level NMAX.

If N is a vector of integers such that $1 \le N(j) \le NMAX$:

- DCELL = detcoef(C,L,N,'cells') returns a cell array where DCELL{j} contains the coefficients of detail N(j).
- If length(N) > 1, DCELL = detcoef(C,L,N) is equivalent to DCELL = detcoef(C,L,N,'cells').
- DCELL = detcoef(C,L,'cells') is equivalent to DCELL = detcoef(C,L, [1:NMAX]).
- [D1, ..., Dp] = detcoef(C,L,[N(1), ..., N(p)]) extracts the details coefficients at levels [N(1), ..., N(p)].

Examples

```
% The current extension mode is zero-padding (see dwtmode).
```

```
% Load original one-dimensional signal.
```

```
load leleccum;
s = leleccum(1:3920);
% Perform decomposition at level 3 of s using db1.
[c,1] = wavedec(s,3,'db1');
% Extract detail coefficients at levels
% 1, 2 and 3, from wavelet decomposition
% structure [c,1].
[cd1,cd2,cd3] = detcoef(c,1,[1 2 3]);

appcoef | wavedec

detcoef2

2-D detail coefficients

Syntax

```
D = detcoef2(0,C,S,N)
```

Description

detcoef2 is a two-dimensional wavelet analysis function.

D = detcoef2(0,C,S,N) extracts from the wavelet decomposition structure [C,S] the horizontal, vertical, or diagonal detail coefficients for 0 = 'h'(or'v'or'd', respectively), at level N, where N must be an integer such that $1 \le N \le size(S,1)-2$. See wavedec2 for more information on C and S.

[H,V,D] = detcoef2('all',C,S,N) returns the horizontal H, vertical V, and diagonal D detail coefficients at level N.

D = detcoef2('compact', C, S, N) returns the detail coefficients at level N, stored row-wise.

```
detcoef2('a',C,S,N) is equivalent to detcoef2('all',C,S,N).
detcoef2('c',C,S,N) is equivalent to detcoef2('compact',C,S,N).
```

Examples

```
% The current extension mode is zero-padding (see dwtmode).
% Load original image.
load woman;
% X contains the loaded image.
```

```
% Perform decomposition at level 2
% of X using db1.
[c,s] = wavedec2(X,2,'db1');
sizex = size(X)
sizex =
    256
           256
sizec = size(c)
sizec =

displs

Display lifting scheme

Syntax

```
S = displs(LS, FRM)
```

Description

S = displs(LS,FRM) returns a string describing the lifting scheme LS. The format string FRM (see sprintf) builds S.

```
displs(LS) is equivalent to DISPLS(LS, '%12.8f')
```

For more information about lifting schemes, see lsinfo.

Examples

```
% Start from the Haar wavelet and get the
% corresponding lifting scheme.
lshaar = liftwave('haar');
% Visualize the obtained lifting scheme.
displs(lshaar);
lshaar = {...}
' d '
                [ -1.00000000]
                [ 0.50000000] [0]
[ 1.41421356] [ 0.70710678]
};
% Add a primal ELS to the lifting scheme.
els = {'p',[-0.125 0.125],0};
lsnew = addlift(lshaar,els);
displs(lsnew);
lsnew = {...}
```

drawtree

Draw wavelet packet decomposition tree (GUI)

Syntax

```
drawtree(T)
F = drawtree(T)
drawtree(T,F)
```

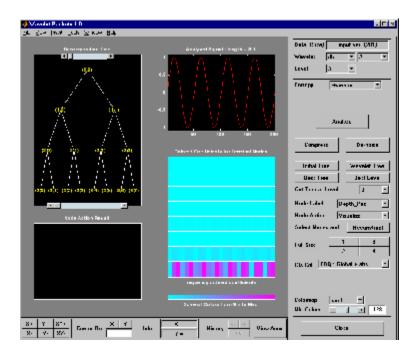

Description

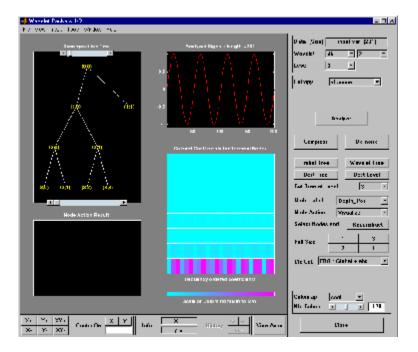

drawtree(T) draws the wavelet packet tree T, and F = drawtree(T) also returns the figure's handle.

For an existing figure F produced by a previous call to the drawtree function, drawtree(T,F) draws the wavelet packet tree T in the figure whose handle is F.

Examples

```
x = sin(8*pi*[0:0.005:1]);
t = wpdec(x,3,'db2');
fig = drawtree(t);
```

readtree

dtfilters

Analysis and synthesis filters for oversampled wavelet filter banks

Syntax

```
df = dtfilters(name)
[df,rf] = dtfilters(name)
```

Description

df = dtfilters(name) returns the decomposition (analysis) filters corresponding to the string, name.

[df,rf] = dtfilters(name) returns the reconstruction (synthesis) filters corresponding to the string, name.

Examples

Filters for Complex Dual-Tree Wavelet Transform

Obtain valid filters for the complex dual-tree wavelet transform. The transform uses Farras nearly symmetric filters for the first stage and Kingsbury Q-shift filters with 10 taps for subsequent stages.

Load the noisy Doppler signal. Obtain the filters for the first and subsequent stages of the complex dual-tree wavelet transform. Demonstrate perfect reconstruction using the complex dual-tree wavelet transform.

```
load noisdopp;
df = dtfilters('dtf2');
dt = dddtree('cplxdt',noisdopp,5,df{1},df{2});
xrec = idddtree(dt);
max(abs(noisdopp-xrec))
```

Filters for Double-Density Wavelet Transform

Obtain valid filters for the double-density wavelet transform.

Load the noisy Doppler signal. Obtain the filters for the double-density wavelet transform. The double-density wavelet transform uses the same filters at all stages. Demonstrate perfect reconstruction using the double-density wavelet transform.

```
df = dtfilters('filters1');
load noisdopp;
dt = dddtree('ddt',noisdopp,5,df,df);
xrec = idddtree(dt);
max(abs(noisdopp-xrec))
```

Input Arguments

```
name — Filter name
'dtf1' | 'dddtf1' | 'self1' | 'self2' | ...
```

Filter name, specified as a string. Valid entries for name are:

- Any valid orthogonal or biorthogonal wavelet name. See wfilters for details. An orthogonal or biorthogonal wavelet is only valid when the filter bank type is 'dwt', or when you use the filter as the first stage in a complex dual-tree transform, 'realdt' or 'cplxdt'. An orthogonal or biorthogonal wavelet filter is not a valid filter if you have a double-density, 'ddt' or dual-tree double-density, 'realdddt' or 'cplxdddt', filter bank. An orthogonal or biorthogonal wavelet filter is not a valid filter for complex dual-tree filter banks for stages greater than 1.
- 'dtfP' With P equal to 1, 2, 3, or 4 returns the first-stage Farras filters
 ('FSfarras') and Kingsbury Q-shift filters ('qshiftN' for subsequent stages.
 This input is only valid for a dual-tree transform, 'realdt' or 'cplxdt'. Setting P= 1, 2, 3, or 4 specifies the Kingsbury Q-shift filters with N = 6, 10, 14, or 18 taps respectively.
- 'dddtf1' Returns the filters for the first and subsequent stages of the double-density dual-tree transform. This input is only valid for the double-density dual-tree transforms, 'realdddt' and 'cplxdddt'.
- 'self1' Returns 10-tap filters for the double-density wavelet transform. This
 option is only valid for double-density wavelet transforms, 'ddt', 'realdddt', and
 'cplxdddt'.
- 'self2' Returns 16-tap filters for the double-density wavelet transform. This
 option is only valid for double-density wavelet transforms, 'ddt', 'realdddt', and
 'cplxdddt'.

- 'filters1' Returns 6-tap filters for the double-density wavelet transform,
 'ddt'.
- 'filters2' Returns 12-tap filters for the double-density wavelet transform, 'ddt'.
- 'farras' Farras nearly symmetric filters for a two-channel perfect reconstruction filter bank. This option is only valid for an orthogonal critically sampled wavelet transform, 'dwt'.
- he 'FSfarras' Farras nearly symmetric first-stage filters for a dual-tree wavelet transform.
- 'qshiftN' Kingsbury Q-shift N-tap filters with N = 6,10,14, or 18. The Kingsbury Q-shift filters are most commonly used in dual-tree wavelet transforms for stages greater than 1.
- 'doubledualfilt' Filters for one stage of the double-density dual-tree wavelet transforms, 'realdddt' or 'cplxdddt'.

Output Arguments

df — Decomposition (analysis) filters

matrix | cell array

Decomposition (analysis) filters, returned as a matrix or cell array of matrices.

rf — Reconstruction (synthesis) filters

matrix | cell array

Reconstruction (synthesis) filters, returned as a matrix or cell array of matrices.

dddtree | dddtree2

Introduced in R2013b

dtree

DTREE constructor

Syntax

```
T = dtree(ORD,D,X)
T = dtree(ORD,D,X,U)
[T,NB] = dtree(...)
[T,NB] = dtree('PropName1',PropValue1,'PropName2',PropValue2,...)
```

Description

T = dtree(ORD, D, X) returns a complete data tree (DTREE) object of order *ORD* and depth D. The data associated with the tree T is X.

```
With T = dtree(ORD, D, X, U) you can set a user data field.
```

```
[T,NB] = dtree(...) returns also the number of terminal nodes (leaves) of T.
```

[T,NB] = dtree('PropName1',PropValue1,'PropName2',PropValue2,...) is the most general syntax to construct a DTREE object.

The valid choices for 'PropName' are

'order'	Order of the tree	
'depth'	Depth of the tree	
'data'	Data associated to the tree	
'spsch'	Split scheme for nodes	
'ud'	User data field	

The split scheme field is an order ORD by 1 logical array. The root of the tree can be split and it has ORD children. If spsch(j) = 1, you can split the j-th child. Each node that you can split has the same property as the root node.

For more information on object fields, type help dtree/get.

Class DTREE (Parent class: NTREE)

Fields

dtree	Parent object
allNI	All nodes information
terNI	Terminal nodes information

Examples

```
% Create a data tree.
x = [1:10];
t = dtree(3,2,x);
t = nodejoin(t,2);
```

ntree | wtbo

dwt

Single-level discrete 1-D wavelet transform

Syntax

```
[cA,cD] = dwt(X,'wname')
[cA,cD] = dwt(X,Lo_D,Hi_D)
[cA,cD] = dwt(...,'mode',MODE)
```

Description

The dwt command performs a single-level one-dimensional wavelet decomposition with respect to either a particular wavelet ('wname', see wfilters for more information) or particular wavelet decomposition filters (Lo_D and Hi_D) that you specify.

[CA, CD] = dwt(X, 'wname') computes the approximation coefficients vector CA and detail coefficients vector CD, obtained by a wavelet decomposition of the vector X. The string 'wname' contains the wavelet name.

 $[cA,cD] = dwt(X,Lo_D,Hi_D)$ computes the wavelet decomposition as above, given these filters as input:

- Lo_D is the decomposition low-pass filter.
- · Hi_D is the decomposition high-pass filter.

Lo_D and Hi_D must be the same length.

Let $lx = the length of X and <math>lf = the length of the filters Lo_D and Hi_D; then length(cA) = length(cD) = la where <math>la = ceil(lx/2)$, if the DWT extension mode is set to periodization. For the other extension modes, la = floor(lx+lf-1)/2.

For more information about the different Discrete Wavelet Transform extension modes, see dwtmode.

[CA,CD] = dwt(..., 'mode', MODE) computes the wavelet decomposition with the extension mode MODE that you specify. MODE is a string containing the desired extension mode.

Example:

```
[cA,cD] = dwt(x,'db1','mode','sym');
```

Examples

DWT Using Wavelet Name

Obtain the level-1 DWT of the noisy Doppler signal using a wavelet name.

```
load noisdopp;
[A,D] = dwt(noisdopp,'sym4');
```

DWT Using Wavelet and Scaling Filters

Obtain the level-1 DWT of the noisy Doppler signal using wavelet and scaling filters.

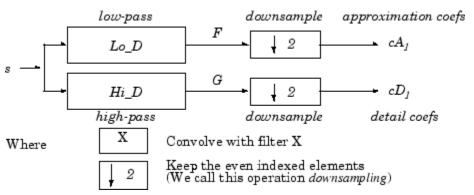

```
load noisdopp;
[Lo_D,Hi_D] = wfilters('bior3.5','d');
[A,D] = dwt(noisdopp,Lo_D,Hi_D);
```

More About

Algorithms

Starting from a signal s of length N, two sets of coefficients are computed: approximation coefficients CA_I , and detail coefficients CD_I . These vectors are obtained by convolving s with the low-pass filter Lo_D for approximation and with the high-pass filter Hi_D for detail, followed by dyadic decimation.

More precisely, the first step is

The length of each filter is equal to 2L. For signal of length N, the signals F and G are of length N + 2L - 1, and then the coefficients CA_I and CD_I are of length

$$\left| \frac{N-1}{2} + L \right|$$
.

To deal with signal-end effects involved by a convolution-based algorithm, a global variable managed by dwtmode is used. This variable defines the kind of signal extension mode used. The possible options include zero-padding (used in the previous example) and symmetric extension, which is the default mode.

Note For the same input, this dwt function and the DWT block in the Signal Processing ToolboxTM do not produce the same results. The blockset is designed for real-time implementation while Wavelet ToolboxTM software is designed for analysis, so they produce handle boundary conditions and filter states differently.

To make the dwt function output match the DWT block output, set the function boundary condition to zero-padding by typing dwtmode ('zpd') at the MATLAB command prompt. To match the latency of the DWT block, which is implemented using FIR filters, add zeros to the input of the dwt function. The number of zeros you add must be equal to half the filter length.

dwt2

Single-level discrete 2-D wavelet transform

Syntax

```
[cA,cH,cV,cD] = dwt2(X,'wname')
[cA,cH,cV,cD] = dwt2(X,Lo_D,Hi_D)
[cA,cH,cV,cD] = dwt2(...,'mode',MODE)
```

Description

The dwt2 command performs a single-level two-dimensional wavelet decomposition with respect to either a particular wavelet ('wname', see wfilters for more information) or particular wavelet decomposition filters (Lo_D and Hi_D) you specify.

[cA,cH,cV,cD] = dwt2(X,'wname') computes the approximation coefficients matrix cA and details coefficients matrices cH, cV, and cD (horizontal, vertical, and diagonal, respectively), obtained by wavelet decomposition of the input matrix X. The 'wname' string contains the wavelet name.

[cA,cH,cV,cD] = dwt2(X,Lo_D,Hi_D) computes the two-dimensional wavelet decomposition as above, based on wavelet decomposition filters that you specify.

- · Lo_D is the decomposition low-pass filter.
- Hi_D is the decomposition high-pass filter.

Lo_D and Hi_D must be the same length.

```
Let sx = size(X) and lf = the length of filters; then <math>size(cA) = size(cH) = size(cV) = size(cD) = sa where sa = ceil(sx/2), if the DWT extension mode is set to periodization. For the other extension modes, sa = floor((sx+lf-1)/2).
```

For information about the different Discrete Wavelet Transform extension modes, see dwtmode.

[cA,cH,cV,cD] = dwt2(..., 'mode', MODE) computes the wavelet decomposition with the extension mode MODE that you specify.

MODE is a string containing the desired extension mode.

An example of valid use is

```
[cA,cH,cV,cD] = dwt2(x,'db1','mode','sym');
```

2-D DWT of Image

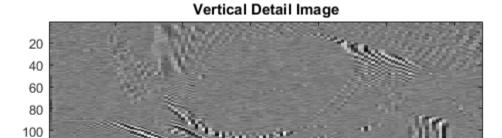

This example shows how to obtain the 2-D DWT of an image.

Load the "woman" image and obtain the 2-D DWT using the 'sym4' wavelet. Use the periodic extension mode.

```
load woman;
wname = 'sym4';
[CA,CH,CV,CD] = dwt2(X,wname,'mode','per');
```

Display the vertical detail image and the lowpass approximation.

```
subplot(211)
imagesc(CV); title('Vertical Detail Image');
colormap gray;
subplot(212)
imagesc(CA); title('Lowpass Approximation');
```

Tips

120

When X represents an indexed image, then X, as well as the output arrays cA,cH,cV,cD are m-by-n matrices. When X represents a truecolor image, it is an m-by-n-by-3 array, where each m-by-n matrix represents a red, green, or blue color plane concatenated along the third dimension.

For more information on image formats, see the image and imfinfo reference pages.

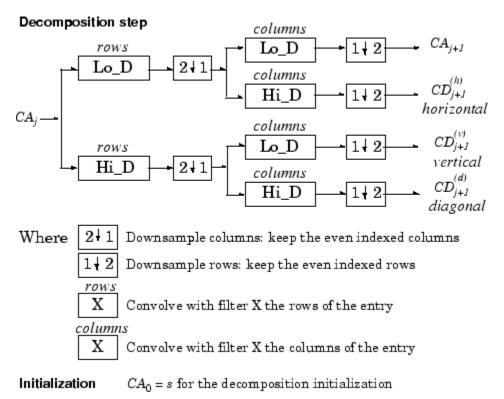

Algorithms

For images, there exist an algorithm similar to the one-dimensional case for twodimensional wavelets and scaling functions obtained from one-dimensional ones by tensorial product.

This kind of two-dimensional DWT leads to a decomposition of approximation coefficients at level j in four components: the approximation at level j + 1, and the details in three orientations (horizontal, vertical, and diagonal).

The following chart describes the basic decomposition steps for images:

Two-Dimensional DWT

Note To deal with signal-end effects involved by a convolution-based algorithm, a global variable managed by dwtmode is used. This variable defines the kind of signal extension

mode used. The possible options include zero-padding (used in the previous example) and symmetric extension, which is the default mode.

dwt3

Single-level discrete 3-D wavelet transform

Syntax

```
WT = dwt3(X,'wname')
WT = dwt3(X,'wname','mode','ExtM')
WT = dwt3(X,W,...)
WT = dwt3(X,WF,...)
```

Description

dwt3 performs a single-level three-dimensional wavelet decomposition using either a particular wavelet ('wname') or the wavelet decomposition and reconstruction filters you specify. The decomposition also uses the specified DWT extension mode (see dwtmode).

WT = dwt3(X, 'wname') returns the 3-D wavelet transform of the 3-D array X 'wname' is a string containing the wavelet name. The default extension mode is 'sym'. For more information on wname, see wfilters.

```
WT = dwt3(X, 'wname', 'mode', 'ExtM') uses the extension mode 'ExtM'.
```

WT is a structure with the following fields shown in the table.

sizeINI	Size of the three-dimensional array X.	
mode	Name of the wavelet transform extension mode.	
filters	Structure with four fields: LoD, HiD, LoR, HiR, which are the filters used for DWT.	
dec	2 x 2 x 2 cell array containing the coefficients of the decomposition. dec{i,j,k}, i,j,k = 1 or 2 contains the coefficients obtained	
	by low-pass filtering (for i or j or k = 1) or high-pass filtering (for i or j or k = 2)	

WT = dwt3(X,W,...) specify three wavelets, one for each direction. W = {'wname1', 'wname2', 'wname3'} or W is a structure with 3 fields 'w1', 'w2', 'w3' containing strings that are the names of wavelets.

WT = dwt3(X,WF,...) specify four filters, two for decomposition, and two for reconstructionm or 3×4 filters (one quadruplet by direction). WF is either a cell array (1 x 4) or (3 x 4): {LoD,HiD,LoR,HiR} or a structure with the four fields 'LoD','HiD','LOR','HiR'.

Examples

```
% Define the original 3-D data.

Introduced in R2010a

dwtmode

Discrete wavelet transform extension mode

Syntax

```
ST = dwtmode
ST = dwtmode('status')
dwtmode('mode')
```

Description

dwtmode sets the signal or image extension mode for discrete wavelet and wavelet packet transforms. The extension modes represent different ways of handling the problem of border distortion in signal and image analysis. For more information, see "Border Effects", in the User's Guide.

dwtmode or dwtmode ('status') display the current mode.

ST = dwtmode or ST = dwtmode('status') display and returns in <math>ST the current mode.

ST = dwtmode('status', 'nodisp') returns in ST the current mode and no text (status or warning) is displayed in the MATLAB Command Window.

dwtmode('mode') sets the DWT extension mode according to the value of 'mode':

'mode'	DWT Extension Mode
'sym' or 'symh'	Symmetric-padding (half-point): boundary value symmetric replication — default mode
'symw'	Symmetric-padding (whole-point): boundary value symmetric replication
'asym' or 'asymh'	Antisymmetric-padding (half-point): boundary value antisymmetric replication
'asymw'	Antisymmetric-padding (whole-point): boundary value antisymmetric replication

'mode'	DWT Extension Mode
'zpd'	Zero-padding
'spd' or 'sp1'	Smooth-padding of order 1 (first derivative interpolation at the edges)
'sp0'	Smooth-padding of order 0 (constant extension at the edges)
'ppd'	Periodic-padding (periodic extension at the edges)

For more information on symmetric extension modes see "References".

The DWT associated with these five modes is slightly redundant. But, the IDWT ensures a perfect reconstruction for any of the five previous modes whatever is the extension mode used for DWT.

dwtmode('per') sets the DWT mode to periodization.

This mode produces the smallest length wavelet decomposition. But, the extension mode used for IDWT must be the same to ensure a perfect reconstruction.

Using this mode, dwt and dwt2 produce the same results as the obsolete functions dwtper and dwtper2, respectively.

All functions and GUI tools involving the DWT (1-D & 2-D) or Wavelet Packet transform (1-D & 2-D) use the specified DWT extension mode.

dwtmode updates a global variable allowing the use of these six signal extensions. The extension mode should only be changed using this function. Avoid changing the global variable directly.

The default mode is loaded from the file DWTMODE.DEF (in the current path) if it exists. If not, the file DWTMODE.CFG (in the toolbox/wavelet/wavelet folder) is used.

dwtmode('save',MODE) saves MODE as the new default mode in the file DWTMODE.DEF (in the current folder). If a file with the same name already exists in the current folder, it is deleted before saving.

dwtmode('save') is equivalent to dwtmode('save', CURRENTMODE).

In these last two cases, the new default mode saved in the file DWTMODE.DEF will be active as default mode in the next MATLAB session.

Examples

```
% If the DWT extension mode global variable does not
% exist, default is Symmetrization.
clear global

dyaddown

Dyadic downsampling

Syntax

```
Y = dyaddown(X,EVENODD)
Y = dyaddown(X)
Y = dyaddown(X,EVENODD, 'type')
Y = dyaddown(X, 'type',EVENODD)
Y = dyaddown(X)
Y = dyaddown(X, 'type')
Y = dyaddown(X,0,'type')
Y = dyaddown(X,EVENODD)
Y = dyaddown(X,EVENODD, 'c')
```

Description

Y = dyaddown(X, EVENODD) where X is a *vector*, returns a version of X that has been downsampled by 2. Whether Y contains the even- or odd-indexed samples of X depends on the value of positive integer EVENODD:

```
    If EVENODD is even, then Y(k) = X(2k).
    If EVENODD is odd, then Y(k) = X(2k+1).
    Y = dyaddown(X) is equivalent to Y = dyaddown(X,0) (even-indexed samples).
```

Y = dyaddown(X, EVENODD, 'type') or Y = dyaddown(X, 'type', EVENODD), where X is a matrix, returns a version of X obtained by suppressing one out of two:

```
Columns of X If 'type' = 'c' Rows of X If 'type' = 'r' Rows and columns of X If 'type' = 'm'
```

according to the parameter EVENODD, which is as above.

```
If you omit the EVENODD or 'type' arguments, dyaddown defaults to EVENODD = 0 (even-indexed samples) and 'type' = 'c' (columns).
```

```
Y = dyaddown(X) is equivalent to Y = dyaddown(X,0,'c').

Y = dyaddown(X,'type') is equivalent to Y = dyaddown(X,0,'type').

Y = dyaddown(X,EVENODD) is equivalent to Y = dyaddown(X,EVENODD,'c').
```

```

dyadup

dyadup

Dyadic upsampling

Syntax

```
Y = dyadup(X,EVENODD)
Y = dyadup(X)
Y = dyadup(X,EVENODD,'type')
Y = dyadup(X,'type',EVENODD)
Y = dyadup(X)
Y = dyaddown(X,1,'c')
Y = dyadup(X,'type')
Y = dyadup(X,1,'type')
Y = dyadup(X,EVENODD)
Y = dyadup(X,EVENODD,'c')
```

Description

dyadup implements a simple zero-padding scheme very useful in the wavelet reconstruction algorithm.

Y = dyadup(X, EVENODD), where X is a vector, returns an extended copy of vector X obtained by inserting zeros. Whether the zeros are inserted as even- or odd-indexed elements of Y depends on the value of positive integer EVENODD:

```
• If EVENODD is even, then Y(2k-1) = X(k), Y(2k) = 0.
```

```
• If EVENODD is odd, then Y(2k-1) = 0, Y(2k) = X(k).
```

Y = dyadup(X) is equivalent to Y = dyadup(X, 1) (odd-indexed samples).

Y = dyadup(X, EVENODD, 'type') or Y = dyadup(X, 'type', EVENODD), where X is a matrix, returns extended copies of X obtained by inserting

Columns in X	If 'type'= 'c'
Rows in X	If 'type'= 'r'

```
Rows and columns in X

If 'type' = 'm'
```

according to the parameter *EVENODD*, which is as above.

If you omit the *EVENODD* or 'type' arguments, dyadup defaults to EVENODD = 1 (zeros in odd-indexed positions) and 'type' = 'c' (insert columns).

```
Y = dyadup(X) is equivalent to Y = dyaddown(X,1,'c').
Y = dyadup(X,'type') is equivalent to Y = dyadup(X,1,'type').
Y = dyadup(X,EVENODD) is equivalent to Y = dyadup(X,EVENODD,'c').
```

```

entrupd

Entropy update (wavelet packet)

Syntax

```
T = entrupd(T, ENT)

T = entrupd(T, ENT, PAR)
```

Description

entrupd is a one- or two-dimensional wavelet packet utility.

T = entrupd(T, ENT) or T = entrupd(T, ENT, PAR) returns for a given wavelet packet tree T, the updated tree using the entropy function ENT with the optional parameter PAR (see wenergy for more information).

```
% The current extension mode is zero-padding (see dwtmode).
% Load signal.
load noisdopp; x = noisdopp;
% Decompose x at depth 2 with db1 wavelet packets
% using shannon entropy.
t = wpdec(x,2,'db1','shannon');
% Read entropy of all the nodes.
nodes = allnodes(t);
ent = read(t,'ent',nodes);

fbspwavf

Complex frequency B-spline wavelet

Syntax

```
[PSI,X] = fbspwavf(LB,UB,N,M,FB,FC)
```

Description

[PSI,X] = fbspwavf(LB,UB,N,M,FB,FC) returns values of the complex frequency B-Spline wavelet defined by the order parameter M (M is an integer such that $1 \le M$), a bandwidth parameter FB, and a wavelet center frequency FC.

The function PSI is computed using the explicit expression

```
PSI(X) = (FB^0.5)*((sinc(FB*X/M).^M).*exp(2*i*pi*FC*X)) on an N point regular grid in the interval [LB,UB].
```

FB and FC must be such that FC > 0 and > FB > 0.

Output arguments are the wavelet function PSI computed on the grid X.

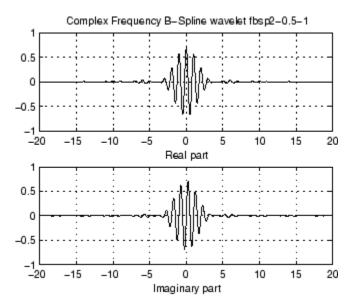

```
% Set order, bandwidth and center frequency parameters.
m = 2; fb = 0.5; fc = 1;

% Set effective support and grid parameters.
lb = -20; ub = 20; n = 1000;

% Compute complex Frequency B-Spline wavelet fbsp2-0.5-1.
[psi,x] = fbspwavf(lb,ub,n,m,fb,fc);

% Plot complex Frequency B-Spline wavelet.
subplot(211)
plot(x,real(psi))
```

```
title('Complex Frequency B-Spline wavelet fbsp2-0.5-1')
xlabel('Real part'), grid
subplot(212)
plot(x,imag(psi))
xlabel('Imaginary part'), grid
```

filt2ls

Transform quadruplet of filters to lifting scheme

Syntax

```
LS = filt2ls(LoD,HiD,LoR,HiR)
```

Description

LS = filt2ls(LoD, HiD, LoR, HiR) returns the lifting scheme LS associated with the four input filters LoD, HiD, LoR, and HiR that verify the perfect reconstruction condition.

```
[LoD,HiD,LoR,HiR] = wfilters('db2')

ls2filt | lsinfo

fejerkorovkin

Fejer-Korovkin wavelet filters

Syntax

```
Lo = fejerkorovkin(wname)
```

Description

Lo = fejerkorovkin(wname) returns the Fejer-Korovkin scaling filter specified by wname. Valid entries for wname are 'fk4', 'fk6', 'fk8', 'fk14', and 'fk22'. For information on the Fejer-Korovkin filters, see Nielson[1].

Examples

Fejer-Korovkin Filters

Lo = fejerkorovkin('fk14')

Construct and plot the Fejer-Korovkin (14) scaling function and wavelet.

Obtain the Fejer-Korovkin scaling filter and display its 14 coefficients.

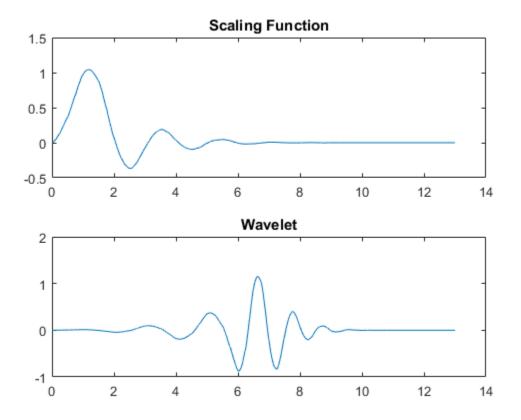

```
Lo =
  Columns 1 through 7
    0.2604
              0.6869
                        0.6116
                                   0.0514
                                            -0.2456
                                                      -0.0486
                                                                  0.1243
  Columns 8 through 14
    0.0222
             -0.0640
                       -0.0051
                                   0.0298
                                            -0.0033
                                                      -0.0093
                                                                  0.0035
```

Use the scaling filter to obtain the wavelet filter and display its wavelet filter coefficients.

```
Hi = qmf(Lo)
Hi =
 Columns 1 through 7
   0.0035
             0.0093
                     -0.0033
                               -0.0298 -0.0051 0.0640
                                                            0.0222
 Columns 8 through 14
   -0.1243
            -0.0486
                      0.2456
                                0.0514
                                         -0.6116
                                                   0.6869
                                                            -0.2604
```

wavefun provides an efficient way to construct and plot the scaling function and wavelet.

```
[phi,psi,xval] = wavefun('fk14');
subplot(2,1,1)
plot(xval,phi)
title('Scaling Function')
subplot(2,1,2)
plot(xval,psi)
title('Wavelet')
```

Input Arguments

```
wname — Filter name
'fk4' | 'fk6' | 'fk8' | 'fk14' | 'fk16' | 'fk22'
```

Filter name, specified as a string. The numeric value in each string is the number of Fejer-Korovkin filter coefficients.

Output Arguments

Lo — Scaling filter

vector

Scaling filter, returned as a vector.

coifwavf | dbwavf | symwavf

Introduced in R2015b

gauswavf

Gaussian wavelet

Syntax

```
[PSI,X] = gauswavf(LB,UB,N,P)
[PSI,X] = gauswavf(LB,UB,N)
[PSI,X] = gauswavf(LB,UB,N,1)
```

Description

[PSI,X] = gauswavf(LB,UB,N,P) returns values of the P-th derivative of the Gaussian function on an N point regular grid for the interval [LB,UB]. Cp is such that the 2-norm of the P-th derivative of F is equal to 1.

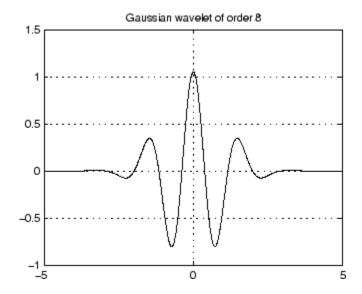

For P > 8, Symbolic Math Toolbox software is required.

Output arguments are the wavelet function PSI computed on the grid X.

```
[PSI,X] = gauswavf(LB,UB,N) is equivalent to
[PSI,X] = gauswavf(LB,UB,N,1).
```

These wavelets have an effective support of [-5 5].

```
% Set effective support and grid parameters.
lb = -5; ub = 5; n = 1000;
% Compute Gaussian wavelet of order 8.
[psi,x] = gauswavf(lb,ub,n,8);
% Plot Gaussian wavelet of order 8.
plot(x,psi),
title('Gaussian wavelet of order 8'), grid
```

See Also waveinfo

get

WPTREE contents

Syntax

```
[FieldValue1,FieldValue2, ...] =
get(T,'FieldName1','FieldName2', ...)
[FieldValue1,FieldValue2, ...] = get(T)
```

Description

```
[FieldValue1, FieldValue2, ...] = get(T, 'FieldName1', 'FieldName2', ...) returns the content of the specified fields for the WPTREE object T.
```

For the fields that are objects or structures, you can get the subfield contents, giving the name of these subfields as 'FieldName' values. (See "Examples" below.)

[FieldValue1, FieldValue2, ...] = get(T) returns all the field contents of the tree T.

The valid choices for 'FieldName' are

'dtree'	DTREE parent object
'wavInfo'	Structure (wavelet information)

The fields of the wavelet information structure, 'wavInfo', are also valid for 'FieldName':

'wavName'	Wavelet name
'Lo_D'	Low Decomposition filter
'Hi_D'	High Decomposition filter
'Lo_R'	Low Reconstruction filter
'Hi_R'	High Reconstruction filter

'entInfo'	Structure (entropy information)	
-----------	---------------------------------	--

The fields of the entropy information structure, 'entInfo', are also valid for 'FieldName':

'entName'	Entropy name
'entPar'	Entropy parameter

Or fields of DTREE parent object:

'ntree'	NTREE parent object
'allNI'	All nodes information
'terNI'	Terminal nodes information

Or fields of NTREE parent object:

'wtbo'	WTBO parent object
'order'	Order of the tree
'depth'	Depth of the tree
'spsch'	Split scheme for nodes
'tn'	Array of terminal nodes of the tree

Or fields of WTBO parent object:

'wtboInfo'	Object information
'ud'	Userdata field

```
% Compute a wavelet packets tree
x = rand(1,1000);
t = wpdec(x,2,'db2');
o = get(t,'order');
[o,tn] = get(t,'order','tn');
[o,allNI,tn] = get(t,'order','allNI','tn');
[o,wavInfo,allNI,tn] = get(t,'order','wavInfo','allNI','tn');
```

```
[o,tn,Lo_D,EntName] = get(t,'order','tn','Lo_D','EntName');
[wo,nt,dt] = get(t,'wtbo','ntree','dtree');
```

disp | read | set | write

icwtft

Inverse CWT

Syntax

```
xrec = icwtft(cwtstruct)
xrec = icwtft(cwtstruct, 'plot')
xrec = icwtft(cwtstruct, 'signal', SIG, 'plot')
```

Description

xrec = icwtft(cwtstruct) returns the inverse continuous wavelet transform of the CWT coefficients contained in the cfs field of the structure array cwtstruct. Obtain the structure array cwtstruct as the output of cwtft.

```
xrec = icwtft(cwtstruct, 'plot') plots the reconstructed signal.
```

xrec = icwtft(cwtstruct, 'signal', SIG, 'plot') places a radio button in the
bottom left corner of the plot. Enabling the radio button superimposes the plot of the
input signal SIG on the plot of the reconstructed signal. By default the radio button is not
enabled and only the reconstructed signal is plotted.

Input Arguments

cwtstruct

Structure array containing six fields.

- · cfs CWT coefficient matrix
- scales Vector of scales
- frequencies frequencies in cycles per unit time (or space) corresponding to the scales. If the sampling period units are seconds, the frequencies are in hertz. The elements of frequencies are in decreasing order to correspond to the elements in the scales vector.

- omega Angular frequencies used in the Fourier transform
- · meanSig Mean of the analyzed signal
- dt The sampling period
- wav Analyzing wavelet used in the CWT with parameters specified

cwtstruct is the output of cwtft.

Output Arguments

xrec

Reconstructed signal

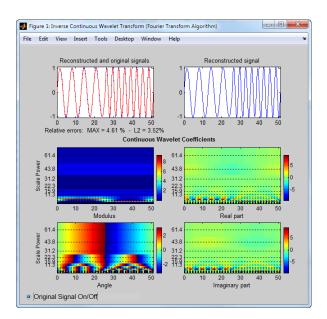

Examples

Compute the CWT and inverse CWT of two sinusoids with disjoint support.

```
N = 1024;
t = linspace(0,1,N);
y = sin(2*pi*8*t).*(t<=0.5)+sin(2*pi*16*t).*(t>0.5);
dt = 0.05;
s0 = 2*dt;
ds = 0.4875;
NbSc = 20;
wname = 'morl';
sig = {y,dt};
sca = {s0,ds,NbSc};
wave = {wname,[]};
cwtsig = cwtft(sig,'scales',sca,'wavelet',wave);

% Compute inverse CWT and plot reconstructed signal with original sigrec = icwtft(cwtsig,'signal',sig,'plot');
```

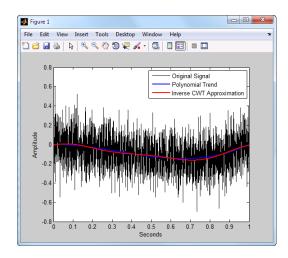

Select the radio button in the bottom left corner of the plot.

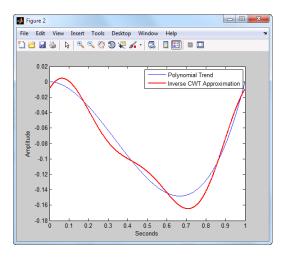

Use the inverse CWT to approximate a trend in a time series. Construct a time series consisting of a polynomial trend, a sinewave (oscillatory component), and additive white Gaussian noise. Obtain the CWT of the input signal and use the inverse CWT based on only the coarsest scales to reconstruct an approximation to the trend. To obtain an accurate approximation based on select scales use the default power of two spacing for the scales in the continuous wavelet transform. See cwtft for details.

```
t = linspace(0,1,1e3);
% Polynomial trend
x = t.^3-t.^2;
% Periodic term
x1 = 0.25*cos(2*pi*250*t);
% Reset random number generator for reproducible results
rng default
y = x+x1+0.1*randn(size(t));
% Obtain CWT of input time series
cwty = cwtft({y,0.001}, 'wavelet', 'morl');
% Zero out all but the coarsest scale CWT coefficients
cwtv.cfs(1:16,:) = 0;
% Reconstruct a signal approximation based on the coarsest scales
xrec = icwtft(cwty);
plot(t,y,'k'); hold on;
xlabel('Seconds'); ylabel('Amplitude');
```

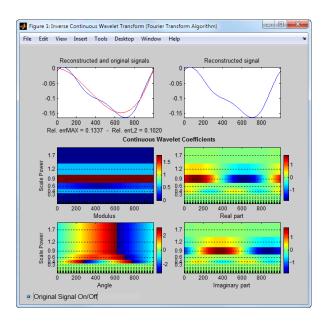

```
plot(t,x,'b','linewidth',2);
plot(t,xrec,'r','linewidth',2);
legend('Original Signal','Polynomial Trend',...
    'Inverse CWT Approximation');
figure
plot(t,x,'b'); hold on;
xlabel('Seconds'); ylabel('Amplitude');
plot(t,xrec,'r','linewidth',2);
legend('Polynomial Trend','Inverse CWT Approximation');
```

You can also use the following syntax to plot the approximation. Select the radio button to view the original polynomial trend superimposed on the wavelet approximation.

% Input the polynomial trend as the value of 'signal'
xrec = icwtft(cwty, 'signal', x, 'plot');

More About

Inverse CWT

icwtft computes the inverse CWT based on a discretized version of the single integral formula due to Morlet. The Wavelet Toolbox Getting Started Guide contains a brief description of the theoretical foundation for the single integral formula in "Inverse Continuous Wavelet Transform". The discretized version of this integral is presented in [5]

- "Continuous and Discrete Wavelet Transforms"
- "Continuous Wavelet Transform and Scale-Based Analysis"
- "Inverse Continuous Wavelet Transform"

cwt | cwtft | icwtlin

Introduced in R2011a

icwtlin

Inverse continuous wavelet transform (CWT) for linearly spaced scales

Syntax

```
xrec = icwtlin(cwtstruct)
xrec = icwtlin(wav,meanSIG,cfs,scales,dt)
xrec = icwtlin(...,'plot')
xrec = icwtlin (...,'signal',SIG,'plot')
xrec = icwtlin(...,Name,Value)
```

Description

xrec = icwtlin(cwtstruct) returns the inverse continuous wavelet transform
(CWT) of the CWT coefficients obtained at linearly spaced scales.

Note: To use icwtlin you must:

- Use linearly-spaced scales in the CWT. icwtlin does not verify that the scales are linearly-spaced.
- Use one of the supported wavelets. See "Input Arguments" on page 1-206 for a list of supported wavelets.

xrec = icwtlin(wav, meanSIG, cfs, scales, dt) returns the inverse CWT of the
coefficients in cfs. The inverse CWT is obtained using the wavelet wav, the linearly
spaced scales scales, the sampling period dt, and the mean signal value meanSig.

xrec = icwtin(..., 'plot') plots the reconstructed signal xrec along with the CWT coefficients and CWT moduli. If the analyzing wavelet is complex-valued, the plot includes the real and imaginary parts of the CWT coefficients.

xrec = icwtlin (..., 'signal', SIG, 'plot') places a radio button in the bottomleft corner of the plot. Enabling the radio button superimposes the plot of the input signal
SIG on the plot of the reconstructed signal. SIG can be a structure array, a cell array, or

a vector. If SIG is a structure array, there must be two fields: val and period. The val field contains the signal and the period field contains the sampling period. If SIG is a cell array, SIG{1} contains the signal and SIG{2} is the sampling period.

xrec = icwtlin(...,Name,Value) returns the inverse CWT transform with
additional options specified by one or more Name,Value pair arguments.

Input Arguments

cwtstruct

A structure array that is the output of cwtft or constructed from the output of cwt. If you obtain cwtstruct from cwtft, the structure array contains seven fields:

- cfs CWT coefficient matrix
- scales Vector of linearly spaced scales. The scale vector must be linearly-spaced
 to ensure accurate reconstruction. icwtlin does not check that the spacing of your
 scale vector is linear.
- frequencies frequencies in cycles per unit time (or space) corresponding to the scales. If the sampling period units are seconds, the frequencies are in hertz. The elements of frequencies are in decreasing order to correspond to the elements in the scales vector.
- omega Angular frequencies used in the Fourier transform in radians/sample
- MeanSIG Signal mean
- dt Sampling period in seconds
- wav Analyzing wavelet. icwtlin uses this wavelet as the reconstruction wavelet.
 The supported wavelets are:
 - ' \log ' An m-th order derivative of Gaussian wavelet where m is a positive even integer
 - 'morl' Analytic Morlet wavelet
 - 'morlex' Nonanalytic Morlet wavelet
 - 'morl0' Nonanalytic Morlet wavelet with exact zero mean
 - 'mexh' Mexican-hat wavelet. This argument represents a special case of the derivative of Gaussian wavelet with m=2.
 - 'paul' Paul wavelet

'bump' — Bump wavelet

If you create cwtstruct from the output of cwt, cwtstruct contains all of the preceding fields except omega.

Using cwt to obtain the CWT coefficients, the valid analyzing wavelets are:

- Coiflets 'coif1', 'coif2', 'coif3', 'coif4', 'coif5'
- Biorthogonal wavelets 'bior2.2', 'bior2.4', 'bior2.6', 'bior2.8', 'bior4.4', 'bior5.5', bior6.8
- Reverse biorthogonal wavelets 'rbio2.2', 'rbio2.4', 'rbio2.6', 'rbio2.8', 'rbio4.4', 'rbio5.5', 'rbio6.8'
- Complex Gaussian wavelets 'cgau2', 'cgau4', 'cgau6', 'cgau8'

Name-Value Pair Arguments

'IdxSc'

Vector of scales to use in the signal reconstruction. Specifying a subset of scales results in a scale-localized approximation of the analyzed signal.

Output Arguments

xrec

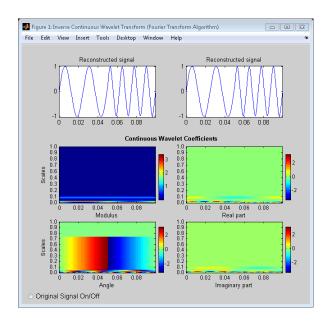

Reconstructed signal. Signal approximation based on the input CWT coefficient matrix, analyzing wavelet, selected scales, and sampling period.

The purpose of the CWT inversion algorithm is not to produce a perfect reconstruction of the input signal. The inversion preserves time and scale-localized features in the reconstructed signal. The amplitude scaling in the reconstructed signal, however, can be significantly different. This difference in scaling can occur whether or not you use all the CWT coefficients in the inversion.

Examples

Compute the inverse CWT of a sum of sine waves with disjoint support.

```
% Define the signal
N = 100;
t = linspace(0,1,N);
Y = sin(8*pi*t).*(t<=0.5) + sin(16*pi*t).*(t>0.5);
% Define parameters before analysis
dt = 0.001;
maxsca = 1; s0 = 2*dt; ds = 2*dt;
scales = s0:ds:maxsca;
wname = 'morl';
SIG = {Y,dt};
WAV = {wname,[]};
% Compute the CWT using cwtft with linear scales
cwtS = cwtft(SIG,'scales',scales,'wavelet',WAV);
% Compute inverse CWT using linear scales
Yrec = icwtlin(cwtS,'Signal',Y,'plot');
```

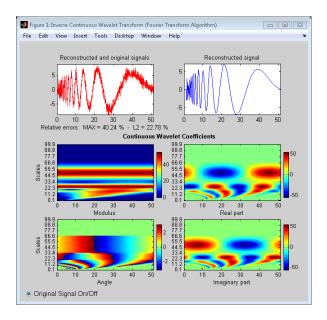

Reconstruct an approximation to a noisy Doppler signal based on thresholded coefficients. Use the universal threshold. Assume the sampling period is 0.05 seconds.

```
load noisdopp;
Y = noisdopp;
```

```
N = length(Y);
% Define parameters before analysis
% Assume sampling period is 0.05
dt = 0.05;
maxsca = 100; s0 = 2*dt; ds = 4*dt;
scales = s0:ds:maxsca;
wname = 'morl';
SIG = \{Y,dt\};
WAV = \{wname, []\};
% Compute CWT
cwtS = cwtft(SIG, 'scales', scales, 'wavelet', WAV, 'plot');
% Select subset of coefficients
cwtS1 = cwtS;
Hfreq = cwtS.cfs(1:10,:);
% Set threshold
thr = sqrt(2*log(N))*median(abs(Hfreq(:)))/0.6745;
newCFS = cwtS.cfs;
% Set coefficients smaller than threshold in absolute value to 0
newCFS(abs(newCFS) < thr) = 0;
cwtS1.cfs = newCFS;
% Reconstruction from the modified structure
YRDen = icwtlin(cwtS1, 'signal', Y, 'plot');
```

Enable the **Reconstructed Signal On/Off** radio button in the bottom-left corner.

Alternatives

• icwtft — Computes the inverse for the CWT obtained using cwtft with logarithmically spaced scales. If you use linearly spaced scales in cwtft, or you obtain the CWT with cwt, use icwtlin to compute the inverse.

More About

Algorithms

See [4] for a description of the inverse CWT algorithm for linearly spaced scales. The icwtlin function uses heuristic scaling factors for the analyzing wavelets. These scaling factors can result in significant differences in the amplitude scaling of the reconstructed signal.

Introduced in R2011b

idddtree

Inverse dual-tree and double-density 1-D wavelet transform

Syntax

```
xrec = idddtree(wt)
```

Description

xrec = idddtree(wt) returns the inverse wavelet transform of the wavelet
decomposition (analysis filter bank), wt. wt is the output of dddtree.

Examples

Perfect Reconstruction Using the Dual-Tree Double-Density Wavelet Filter Bank

Demonstrate perfect reconstruction of a signal using a dual-tree double-density wavelet transform.

Load the noisy Doppler signal. Obtain the dual-tree double-density wavelet transform down to level 5. Invert the transform and demonstrate perfect reconstruction.

"Analytic Wavelets Using the Dual-Tree Wavelet Transform"

Input Arguments

```
wt — Wavelet transform
```

structure

Wavelet transform, returned as a structure from dddtree with these fields:

type — Type of wavelet decomposition (filter bank)

'dwt' | 'ddt' | 'cplxdt' | 'cplxdddt'

Type of wavelet decomposition (filter bank), specified as one of 'dwt', 'ddt', 'cplxdt', or 'cplxdddt'. The type, 'dwt', gives a critically sampled discrete wavelet transform. The other types are oversampled wavelet transforms. 'ddt' is a double-density wavelet transform, 'cplxdt' is a dual-tree complex wavelet transform, and 'cplxdddt' is a double-density dual-tree complex wavelet transform.

1eve1 — Level of wavelet decomposition

positive integer

Level of wavelet decomposition, specified as a positive integer.

filters — Decomposition (analysis) and reconstruction (synthesis) filters

structure

Decomposition (analysis) and reconstruction (synthesis) filters, specified as a structure with these fields:

Fdf — First-stage analysis filters

matrix | cell array

First-stage analysis filters, specified as an *N*-by-2 or *N*-by-3 matrix for single-tree wavelet transforms, or a cell array of two *N*-by-2 or *N*-by-3 matrices for dual-tree wavelet transforms. The matrices are *N*-by-3 for the double-density wavelet transforms. For an *N*-by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an *N*-by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the first-stage analysis filters for the corresponding tree.

Df — Analysis filters for levels > 1

matrix | cell array

Analysis filters for levels > 1, specified as an N-by-2 or N-by-3 matrix for single-tree wavelet transforms, or a cell array of two N-by-2 or N-by-3 matrices for dual-tree wavelet transforms. The matrices are N-by-3 for the double-density wavelet transforms. For an N-by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second

column is the wavelet (highpass) filter. For an *N*-by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the analysis filters for the corresponding tree.

Frf — First-level reconstruction filters

matrix | cell array

First-level reconstruction filters, specified as an *N*-by-2 or *N*-by-3 matrix for single-tree wavelet transforms, or a cell array of two *N*-by-2 or *N*-by-3 matrices for dual-tree wavelet transforms. The matrices are *N*-by-3 for the double-density wavelet transforms. For an *N*-by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an *N*-by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the first-stage synthesis filters for the corresponding tree.

Rf — Reconstruction filters for levels > 1

matrix | cell array

Reconstruction filters for levels > 1, specified as an N-by-2 or N-by-3 matrix for single-tree wavelet transforms, or a cell array of two N-by-2 or N-by-3 matrices for dual-tree wavelet transforms. The matrices are N-by-3 for the double-density wavelet transforms. For an N-by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N-by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the synthesis filters for the corresponding tree.

cfs — Wavelet transform coefficients

cell array of matrices

Wavelet transform coefficients, specified as a 1-by-(level+1) cell array of matrices. The size and structure of the matrix elements of the cell array depend on the type of wavelet transform as follows:

- 'dwt' cfs{j}
 - i = 1,2,... level is the level.
 - cfs{level+1} are the lowpass, or scaling, coefficients.
- 'ddt' cfs{j}(:,:,k)

- j = 1,2,... level is the level.
- k = 1,2 is the wavelet filter.
- cfs{level+1}(:,:) are the lowpass, or scaling, coefficients.
- 'cplxdt' cfs{j}(:,:,m)
 - j = 1,2,... level is the level.
 - m = 1,2 are the real and imaginary parts.
 - cfs{level+1}(:,:) are the lowpass, or scaling, coefficients.
- 'cplxdddt' cfs{j}(:,:,k,m)
 - j = 1,2 level is the level.
 - k = 1,2 is the wavelet filter.
 - m = 1,2 are the real and imaginary parts.
 - cfs{level+1}(:,:) are the lowpass, or scaling, coefficients.

Output Arguments

xrec — Synthesized 1-D signal

vector

Synthesized 1-D signal, returned as a vector. The row or column orientation of xrec depends on the row or column orientation of the 1-D signal input to dddtree.

Data Types: double

idddtree2

Inverse dual-tree and double-density 2-D wavelet transform

Syntax

```
xrec = idddtree2(wt)
```

Description

xrec = idddtree2(wt) returns the inverse wavelet transform of the 2-D
decomposition (analysis filter bank), wt. wt is the output of dddtree2.

Examples

Perfect Reconstruction Using the Complex Oriented Dual-Tree Wavelet Filter Bank

Demonstrate perfect reconstruction of an image using a complex oriented dual-tree wavelet transform.

Load the image and obtain the complex oriented dual-tree wavelet transform down to level 5 using dddtree2. Reconstruct the image using idddtree2 and demonstrate perfect reconstruction.

```
load woman;
wt = dddtree2('cplxdt',X,5,'dtf2');
xrec = idddtree2(wt);
max(max(abs(X-xrec)))
```

"Analytic Wavelets Using the Dual-Tree Wavelet Transform"

Input Arguments

wt — Wavelet transform

structure

Wavelet transform, returned as a structure from dddtree2 with these fields:

type — Type of wavelet decomposition (filter bank)

```
'dwt' | 'ddt' | 'realdt' | 'cplxdt' | 'realdddt' | 'cplxdddt'
```

Type of wavelet decomposition (filter bank), specified as one of 'dwt', 'ddt', 'realdt', 'cplxdt', 'realdddt', or 'cplxdddt'. 'dwt' is the critically sampled DWT. 'ddt' produces a double-density wavelet transform with one scaling and two wavelet filters for both row and column filtering. 'realdt' and 'cplxdt' produce oriented dual-tree wavelet transforms consisting of two and four separable wavelet transforms. 'realdddt' and 'cplxdddt' produce double-density dual-tree wavelet transforms consisting of two and four separable wavelet transforms.

1evel — Level of the wavelet decomposition

positive integer

Level of the wavelet decomposition, specified as a positive integer.

filters — Decomposition (analysis) and reconstruction (synthesis) filters

structure

Decomposition (analysis) and reconstruction (synthesis) filters, specified as a structure with these fields:

Fdf — First-stage analysis filters

matrix | cell array

First-stage analysis filters, specified as an *N*-by-2 or *N*-by-3 matrix for single-tree wavelet transforms, or a 1-by-2 cell array of two *N*-by-2 or *N*-by-3 matrices for dual-tree wavelet transforms. The matrices are *N*-by-3 for the double-density wavelet transforms. For an *N*-by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an *N*-by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the first-stage analysis filters for the corresponding tree.

Df — Analysis filters for levels > 1

matrix | cell array

Analysis filters for levels > 1, specified as an N-by-2 or N-by-3 matrix for single-tree wavelet transforms, or a 1-by-2 cell array of two N-by-2 or N-by-3 matrices for dual-tree wavelet transforms. The matrices are N-by-3 for the double-density wavelet transforms. For an N-by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N-by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the

wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the analysis filters for the corresponding tree.

Frf — First-level reconstruction filters

matrix | cell array

First-level reconstruction filters, specified as an *N*-by-2 or *N*-by-3 matrix for single-tree wavelet transforms, or a 1-by-2 cell array of two *N*-by-2 or *N*-by-3 matrices for dual-tree wavelet transforms. The matrices are *N*-by-3 for the double-density wavelet transforms. For an *N*-by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an *N*-by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the first-stage synthesis filters for the corresponding tree.

Rf — Reconstruction filters for levels > 1

cfs — Wavelet transform coefficients

cell array of matrices

Wavelet transform coefficients, specified as a 1-by-(level+1) cell array of matrices. The size and structure of the matrix elements of the cell array depend on the type of wavelet transform as follows:

- 'dwt' cfs{j}(:,:,d)
 - j = 1,2,... level is the level.
 - d = 1.2.3 is the orientation.
 - $cfs{level+1}(:,:)$ are the lowpass, or scaling, coefficients.
- 'ddt' cfs{j}(:,:,d)
 - j = 1,2,... level is the level.

```
• d = 1,2,3,4,5,6,7,8 is the orientation.
```

- cfs{level+1}(:,:) are the lowpass, or scaling, coefficients.
- 'realddt' cfs{j}(:,:,d,k)
 - j = 1,2,... level is the level.
 - d = 1,2,3 is the orientation.
 - k = 1,2 is the wavelet transform tree.
 - cfs{level+1}(:,:) are the lowpass, or scaling, coefficients.
- 'cplxdt' cfs{j}(:,:,d,k,m)
 - j = 1,2,... level is the level.
 - d = 1,2,3 is the orientation.
 - k = 1,2 is the wavelet transform tree.
 - m = 1,2 are the real and imaginary parts.
 - cfs{level+1}(:,:) are the lowpass, or scaling, coefficients..
- 'realdddt' cfs{j}(:,:,d,k)
 - j = 1,2,... level is the level.
 - d = 1,2,3 is the orientation.
 - k = 1,2 is the wavelet transform tree.
 - cfs{level+1}(:,:) are the lowpass, or scaling, coefficients.
- 'cplxdddt' cfs{j}(:,:,d,k,m)
 - j = 1,2,... level is the level.
 - d = 1,2,3 is the orientation.
 - k = 1,2 is the wavelet transform tree.
 - m = 1,2 are the real and imaginary parts.
 - cfs{level+1}(:,:) are the lowpass, or scaling, coefficients.

Output Arguments

xrec — Synthesized 2-D image matrix

Synthesized image, returned as a matrix.

Data Types: double

Introduced in R2013b

idwt

Single-level inverse discrete 1-D wavelet transform

Syntax

```
X = idwt(cA,cD,'wname')
X = idwt(cA,cD,Lo_R,Hi_R)
X = idwt(cA,cD,'wname',L)
X = idwt(cA,cD,Lo_R,Hi_R,L)
idwt(cA,cD,'wname')
X = idwt(...,'mode',MODE)
X = idwt(cA,[],...)
X = idwt([],cD,...)
```

Description

The idwt command performs a single-level one-dimensional wavelet reconstruction with respect to either a particular wavelet ('wname', see wfilters for more information) or particular wavelet reconstruction filters (Lo_R and Hi_R) that you specify.

X = idwt(cA, cD, 'wname') returns the single-level reconstructed approximation coefficients vector X based on approximation and detail coefficients vectors CA and CD, and using the wavelet 'wname'.

X = idwt(cA,cD,Lo R,Hi R) reconstructs as above using filters that you specify.

- Lo_R is the reconstruction low-pass filter.
- · Hi_R is the reconstruction high-pass filter.

Lo_R and Hi_R must be the same length.

Let la be the length of cA (which also equals the length of cD) and lf the length of the filters Lo_R and Hi_R ; then length(X) = LX where LX = 2*la if the DWT extension mode is set to periodization. For the other extension modes LX = 2*la-lf+2.

For more information about the different Discrete Wavelet Transform extension modes, see dwtmode.

X = idwt(cA,cD,'wname',L) or X = idwt(cA,cD,Lo_R,Hi_R,L) returns the length-L central portion of the result obtained using idwt(cA,cD,'wname'). L must be less than LX.

X = idwt(..., 'mode', MODE) computes the wavelet reconstruction using the specified extension mode MODE.

X = idwt(cA,[],...) returns the single-level reconstructed approximation coefficients vector X based on approximation coefficients vector cA.

X = idwt([],cD,...) returns the single-level reconstructed detail coefficients vector X based on detail coefficients vector CD.

Examples

Inverse DWT Using Orthogonal Wavelet

Demonstrate perfect reconstruction using dwt and idwt with an orthonormal wavelet.

```
load noisdopp;
[A,D] = dwt(noisdopp,'sym4');
x = idwt(A,D,'sym4');
max(abs(noisdopp-x))
```

Inverse DWT Using Biorthgonal Wavelet

Demonstrate perfect reconstruction using dwt and idwt with a biorthogonal wavelet.

```
load noisdopp;
[Lo_D,Hi_D,Lo_R,Hi_R] = wfilters('bior3.5');
[A,D] = dwt(noisdopp,Lo_D,Hi_D);
x = idwt(A,D,Lo_R,Hi_R);
max(abs(noisdopp-x))
```

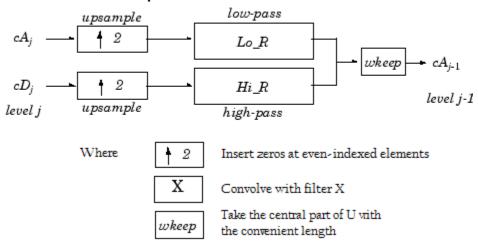

More About

Algorithms

Starting from the approximation and detail coefficients at level j, cAj and cD_j , the inverse discrete wavelet transform reconstructs cA_{j-1} , inverting the decomposition step by inserting zeros and convolving the results with the reconstruction filters.

One-Dimensional IDWT

Reconstruction step

idwt2

Single-level inverse discrete 2-D wavelet transform

Syntax

```
X = idwt2(cA,cH,cV,cD,'wname')
X = idwt2(cA,cH,cV,cD,Lo_R,Hi_R)
X = idwt2(cA,cH,cV,cD,'wname',S)
X = idwt2(cA,cH,cV,cD,Lo_R,Hi_R,S)
idwt2(cA,cH,cV,cD,'wname')
X = idwt2(...,'mode',MODE)
X = idwt2(cA,[],[],[],...)
X = idwt2([],cH,[],[],...)
```

Description

The idwt2 command performs a single-level two-dimensional wavelet reconstruction with respect to either a particular wavelet ('wname', see wfilters for more information) or particular wavelet reconstruction filters (Lo_R and Hi_R) that you specify.

X = idwt2(cA,cH,cV,cD,'wname') uses the wavelet 'wname' to compute the single-level reconstructed approximation coefficients matrix X, based on approximation matrix cA and details matrices cH,cV, and cD (horizontal, vertical, and diagonal, respectively).

X = idwt2(cA,cH,cV,cD,Lo_R,Hi_R) reconstructs as above, using filters that you specify.

- Lo_R is the reconstruction low-pass filter.
- Hi_R is the reconstruction high-pass filter.

Lo_R and Hi_R must be the same length.

Let sa = size(cA) = size(cH) = size(cV) = size(cD) and If the length of the filters; then size(X) = SX, where SX = 2*SA, if the DWT extension mode is set to periodization. For the other extension modes, SX = 2*size(cA) - 1f + 2.

For more information about the different Discrete Wavelet Transform extension modes, see dwtmode.

```
X = idwt2(cA, cH, cV, cD, 'wname', S) and X = idwt2(cA, cH, cV, cD, Lo_R, Hi_R, S) return the size-S central portion of the result obtained using the syntax idwt2(cA, cH, cV, cD, 'wname'). S must be less than SX.
```

X = idwt2(..., 'mode', MODE) computes the wavelet reconstruction using the extension mode MODE that you specify.

X = idwt2(cA,[],[],[],...) returns the single-level reconstructed approximation coefficients matrix X based on approximation coefficients matrix CA.

X = idwt2([], CH, [], [], ...) returns the single-level reconstructed detail coefficients matrix X based on horizontal detail coefficients matrix CH.

```
The same result holds for X = idwt2([],[],cV,[],...) and X = idwt2([],[],[],cD,...), based on vertical and diagonal details.
```

More generally, X = idwt2(AA, HH, VV, DD, ...) returns the single-level reconstructed matrix X, where AA can be cA or [], and so on.

idwt2 is the inverse function of dwt2 in the sense that the abstract statement idwt2(dwt2(X, 'wname'), 'wname') would give back X.

Examples

```
% The current extension mode is zero-padding (see dwtmode).
% Load original image.
load woman;
% X contains the loaded image.
sX = size(X);
% Perform single-level decomposition
% of X using db4.
[cA1,cH1,cV1,cD1] = dwt2(X,'db4');
% Invert directly decomposition of X
% using coefficients at level 1.
A0 = idwt2(cA1,cH1,cV1,cD1,'db4',sX);
```

```
% Check for perfect reconstruction.
max(max(abs(X-A0)))
ans =
    3.4176e-10
```

More About

Tips

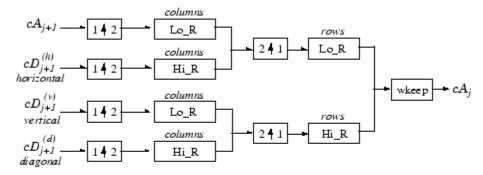

If cA,cH,cV,cD are obtained from an indexed image analysis or a truecolor image analysis, they are M-by-n matrices or M-by-n-by-3 arrays, respectively.

For more information on image formats, see the image and imfinfo reference pages.

Introduced before R2006a

idwt3

Single-level inverse discrete 3-D wavelet transform

Syntax

```
X = idwt3(WT)
C = idwt3(WT,TYPE)
```

Description

The idwt3 command performs a single-level three-dimensional wavelet reconstruction starting from a single-level three-dimensional wavelet decomposition.

X = idwt3(WT) computes the single-level reconstructed 3-D array X, based on the three-dimensional wavelet decomposition stored in the WT structure. This structure contains the following fields.

sizeINI	Size of the three-dimensional array X.
mode	Name of the wavelet transform extension mode.
filters	Structure with 4 fields, LoD, HiD, LoR, HiR, which contain the filters used for DWT.
dec	2 x 2 x 2 cell array containing the coefficients of the decomposition. dec{i,j,k}, i,j,k = 1 or 2 contains the coefficients obtained by
	low-pass filtering (for i or j or k = 1) or high-pass filtering (for i or j or k = 2).

C = idwt3(WT, TYPE) computes the single-level reconstructed component based on the three-dimensional wavelet decomposition. Valid values for TYPE are:

A group of three characters 'xyz', one per direction, with 'x','y' and 'z' selected in the set {'a','d','l','h'} or in the corresponding uppercase set {'A','D','L','H'}), where 'A' (or 'L') specifies low-pass filter and 'D' (or 'H') specifies high-pass filter.

• The char 'd' (or 'h' or 'D' or 'H') which specifies the sum of all the components different from the low-pass component.

Examples

```
% Define original 3D data.
X = reshape(1:64,4,4,4);
% Decompose X using db1.
wt = dwt3(X,'db1');
% Reconstruct X from coefficients.
XR = idwt3(wt);
% Compute reconstructed approximation, i.e. the
% low-pass component.
A = idwt3(wt,'aaa');
% Compute the sum of all the components different
% from the low-pass component.
D = idwt3(wt,'d');
% Reconstruct the component associated with low-pass in the
% X and Z directions and high-pass in the Y direction.
ADA = idwt3(wt,'ada');
```

Introduced in R2010a

ilwt

Inverse 1-D lifting wavelet transform

Syntax

```
X = ilwt(AD_In_Place,W)
X = ilwt(CA,CD,W)
X = ilwt(AD_In_Place,W,LEVEL)
X = ILWT(CA,CD,W,LEVEL)
X = ilwt(AD_In_Place,W,LEVEL,'typeDEC',typeDEC)
X = ilwt(CA,CD,W,LEVEL,'typeDEC',typeDEC)
```

Description

ilwt performs a 1-D lifting wavelet reconstruction with respect to a particular lifted wavelet that you specify.

X = ilwt(AD_In_Place,W) computes the reconstructed vector X using the approximation and detail coefficients vector AD_In_Place obtained by a lifting wavelet reconstruction. W is a lifted wavelet name (see liftwave).

X = ilwt(CA,CD,W) computes the reconstructed vector X using the approximation coefficients vector CA and detail coefficients vector CD obtained by a lifting wavelet reconstruction.

X = ilwt(AD_In_Place,W,LEVEL) or X = ILWT(CA,CD,W,LEVEL) computes the lifting wavelet reconstruction, at level LEVEL.

 $X = ilwt(AD_In_Place,W,LEVEL,'typeDEC',typeDEC) or X = ilwt(CA,CD,W,LEVEL,'typeDEC',typeDEC) with typeDEC = 'w' or 'wp' computes the wavelet or the wavelet packet decomposition using lifting, at level LEVEL.$

Instead of a lifted wavelet name, you may use the associated lifting scheme LS: X = ilwt(...,LS,...) instead of X = ILWT(...,W,...).

For more information about lifting schemes, see lsinfo.

Examples

```
% Start from the Haar wavelet and get the
% corresponding lifting scheme.
lshaar = liftwave('haar');
% Add a primal ELS to the lifting scheme.
els = {'p',[-0.125 0.125],0};
lsnew = addlift(lshaar,els);
% Perform LWT at level 1 of a simple signal.
x = 1:8;
[cA,cD] = lwt(x,lsnew);
% Perform integer LWT of the same signal.
lshaarInt = liftwave('haar','int2int');
lsnewInt = addlift(lshaarInt,els);
[cAint,cDint] = lwt(x,lsnewInt);
% Invert the two transforms.
xRec = ilwt(cA,cD,lsnew);
err = max(max(abs(x-xRec)))
err =
 4.4409e-016
xRecInt = ilwt(cAint,cDint,lsnewInt);
errInt = max(max(abs(x-xRecInt)))
errInt =
     0
```

ilwt2

Inverse 2-D lifting wavelet transform

Syntax

```
X = ilwt2(AD_In_Place,W)
X = ilwt2(CA,CH,CV,CD,W)
X = ilwt2(AD_In_Place,W,LEVEL)
X = ILWT2(CA,CH,CV,CD,W,LEVEL)
X = ilwt2(AD_In_Place,W,LEVEL,'typeDEC',typeDEC)
X = ilwt2(CA,CH,CV,CD,W,LEVEL,'typeDEC',typeDEC)
```

Description

ilwt2 performs a 2-D lifting wavelet reconstruction with respect to a particular lifted wavelet that you specify.

X = ilwt2(AD_In_Place,W) computes the reconstructed matrix X using the approximation and detail coefficients matrix AD_In_Place, obtained by a lifting wavelet decomposition. W is a lifted wavelet name (see liftwave).

X = ilwt2(CA,CH,CV,CD,W) computes the reconstructed matrix X using the approximation coefficients vector CA and detail coefficients vectors CH, CV, and CD obtained by a lifting wavelet decomposition.

```
X = ilwt2(AD_In_Place,W,LEVEL) or X = ILWT2(CA,CH,CV,CD,W,LEVEL)
computes the lifting wavelet reconstruction, at level LEVEL.
```

```
X = ilwt2(AD_In_Place,W,LEVEL, 'typeDEC',typeDEC) or X =
ilwt2(CA,CH,CV,CD,W,LEVEL, 'typeDEC',typeDEC) with typeDEC = 'w' or 'wp'
computes the wavelet or the wavelet packet decomposition using lifting, at level LEVEL.
```

Instead of a lifted wavelet name, you may use the associated lifting scheme LS: X = ilwt2(...,LS,...) instead of X = ilwt2(...,W,...).

For more information about lifting schemes, see lsinfo.

Examples

```
% Start from the Haar wavelet and get the
% corresponding lifting scheme.
lshaar = liftwave('haar');
% Add a primal ELS to the lifting scheme.
els = {'p',[-0.125 0.125],0};
lsnew = addlift(lshaar,els);
% Perform LWT at level 1 of a simple image.
x = reshape(1:16,4,4);
[cA,cH,cV,cD] = lwt2(x,lsnew);
% Perform integer LWT of the same image.
lshaarInt = liftwave('haar','int2int');
lsnewInt = addlift(lshaarInt,els);
[cAint,cHint,cVint,cDint] = lwt2(x,lsnewInt);
% Invert the two transforms.
xRec = ilwt2(cA,cH,cV,cD,lsnew);
err = max(max(abs(x-xRec)))
err =
     0
xRecInt = ilwt2(cAint,cHint,cVint,cDint,lsnewInt);
errInt = max(max(abs(x-xRecInt)))
errInt =
     0
```

More About

Tips

If AD_In_Place or cA,cH,cV,cD are obtained from an indexed image analysis or a truecolor image analysis, they are M-by-n matrices or M-by-n-by-3 arrays, respectively.

For more information on image formats, see the image and imfinfo reference pages.

Introduced before R2006a

imodwt

Inverse maximal overlap discrete wavelet transform

Syntax

```
xrec = imodwt(w)
xrec = imodwt(w,wname)
xrec = imodwt(w,Lo,Hi)
xrec = imodwt(____,lev)
xrec = imodwt(____,'reflection')
```

Description

xrec = imodwt(w) returns in xrec a reconstructed version of the signal. The
reconstructed signal is based on w, the maximal overlap discrete wavelet transform
(MODWT) coefficients and on the level of reconstruction, which defaults to zero.

xrec = imodwt(w,wname) reconstructs the signal using wname, the orthogonal
wavelet. wname must be the same wavelet used to analyze the signal input to modwt. The
reconstruction is up to level 0, which is a perfect reconstruction of the original signal.

xrec = imodwt(w,Lo,Hi) reconstructs the signal using the orthogonal scaling filter Lo and the wavelet filter Hi. The Lo and Hi filters must be the same filters used to analyze the signal input to modwt. The reconstruction is up to level 0, which is a perfect reconstruction of the original signal.

xrec = imodwt(____,lev) reconstructs the signal up to level lev. xrec is a projection
onto the scaling space at level lev.

xrec = imodwt(____, 'reflection') uses the reflection boundary condition in the
reconstruction. If you specify 'reflection', imodwt assumes that the length of the
original signal length is one half the number of columns in the input coefficient matrix.
By default, imodwt assumes periodic signal extension at the boundary.

Examples

Perfect Reconstruction with the Inverse MODWT

Obtain the MODWT of an ECG signal and demonstrate perfect reconstruction.

Load the ECG signal data and obtain the MODWT.

```
load wecg;
```

Obtain the MODWT and the Inverse MODWT.

```
w = modwt(wecg);
xrec = imodwt(w);
```

Use the L-infinity norm to show that the difference between the original signal and the reconstruction is extremely small. The largest absolute difference between the original signal and the reconstruction is on the order of 10^{-12} , which demonstrates perfect reconstruction.

```
norm(abs(xrec'-wecg),Inf)
ans =
2.3253e-12
```

Inverse MODWT with Specified Wavelet

Obtain the MODWT of Deutsche Mark-U.S. Dollar exchange rate data and demonstrate perfect reconstruction.

Load the Deutsche Mark-U.S. Dollar exchange rate data.

```
load DM USD;
```

Obtain the MODWT and the Inverse MODWT using the 'db2' wavelet.

```
wdm = modwt(DM_USD, 'db2');
xrec = imodwt(wdm, 'db2');
```

Use the L-infinity norm to show that the difference between the original signal and the reconstruction is extremely small. The largest absolute difference between the original

signal and the reconstruction is on the order of 10^{-13} , which demonstrates perfect reconstruction.

```
norm(abs(xrec'-DM_USD),Inf)
ans =
1.6362e-13
```

Inverse MODWT with Specified Filters

Obtain the MODWT of an ECG signal using the Fejer-Korovkin filters.

Load the ECG data.

```
load wecg;
```

Create the 8-coefficient Fejer-Korovkin filters.

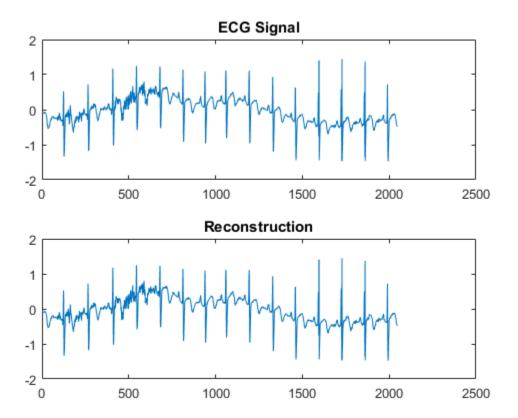

```
[Lo,Hi] = wfilters('fk8');
```

Obtain the MODWT and Inverse MODWT.

```
wtecg = modwt(wecg,Lo,Hi);
xrec = imodwt(wtecg,Lo,Hi);
```

Plot the original data and the reconstruction.

```
subplot(2,1,1)
plot(wecg)
title('ECG Signal');
subplot(2,1,2)
plot(xrec)
title('Reconstruction')
```

Obtain Projection onto Scaling Space

Obtain the MODWT of an ECG signal down to the maximum level and obtain the projection of the ECG signal onto the scaling space at level 3.

Load the ECG data.

```
load wecg;
Obtain the MODWT.
wtecg = modwt(wecg);
```

Obtain the projection of the ECG signal onto V_3 , the scaling space at level three by using the imodwt function.

```
Plot the original signal and the projection.
   subplot(2,1,1)
   plot(wecg)
   title('Original Signal')
   subplot(2,1,2)
   plot(v3proj)
   title('Projection onto V3')

Note that the spikes characteristic of the R waves in the ECG are missing in the V_3 approximation. You can see the missing details by examining the wavelete coefficients at level three.

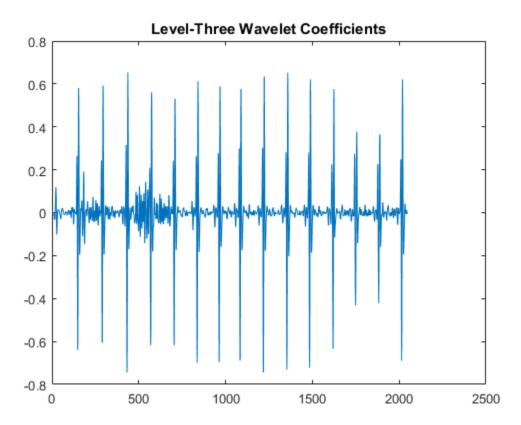

1500

2000

2500

Plot the level-three wavelet coefficients.

```
figure
plot(wtecg(3,:))
title('Level-Three Wavelet Coefficients')
```

Inverse MODWT with Reflection Boundary

Obtain the inverse MODWT using reflection boundary handling for Southern Oscillation Index data. The sampling period is one day. imodwt with the 'reflection' option assumes that the input matrix, which is the modwt output, is twice the length of the original signal length. imodwt reflection boundary handling reduces the number of wavelet and scaling coefficients at each scale by half.

```
load soi;
wsoi = modwt(soi,4,'reflection');
xrecsoi = imodwt(wsoi,'reflection');
```

Use the L-infinity norm to show that the difference between the original signal and the reconstruction is extremely small. The largest absolute difference between the original signal and the reconstruction is on the order of 10^{-11} , which demonstrates perfect reconstruction.

```
norm(abs(xrecsoi'-soi),Inf)
ans =
1.6435e-11
```

Input Arguments

w - MODWT transform

matrix

MODWT transform, specified as a matrix of size L+1-by-N. W is the output of modwt, which is the MODWT of an N-point input signal down to level L. By default, imodwt assumes that you obtained the MODWT using the 'sym4' wavelet with periodic boundary handling.

Data Types: double

```
wname — Synthesis wavelet
'sym4' (default) | 'dbL' | 'coifL' | 'haarL' | 'fkL' | 'symL' | string
```

Synthesis wavelet, specified as a string. The synthesis wavelet must be the same wavelet used in the analysis with modwt.

Lo — Scaling filter

even-length real-valued vector

Scaling filter, specified as an even-length real-valued vector. You can specify Lo only if you do not specify wname. Lo must be the same scaling filter used in the analysis with modwt.

Hi — Wavelet filter

even-length real-valued vector

Wavelet filter, specified as an even-length real-valued vector. You can specify Hi only if you do not specify wname. Hi must be the same wavelet filter used in the analysis with modwt.

1ev — Reconstruction level

0 (default) | nonnegative integer

Reconstruction level, specified as a nonnegative integer between 0 and Size(w,1)-1. If lev is 0 and you do not modify the coefficients, imodwt produces a perfect reconstruction of the signal.

Output Arguments

xrec — Reconstructed signal

row vector

Reconstructed version of the original signal based on the MODWT and the level of reconstruction, returned as a row vector.

ind2depo

Node index to node depth-position

Syntax

```
[D,P] = ind2depo(ORD,[D P])
```

Description

ind2depo is a tree-management utility.

For a tree of order ORD, [D,P] = ind2depo(ORD,N) computes the depths D and the positions P (at these depths D) for the nodes with indices N.

The nodes are numbered from left to right and from top to bottom. The root index is 0.

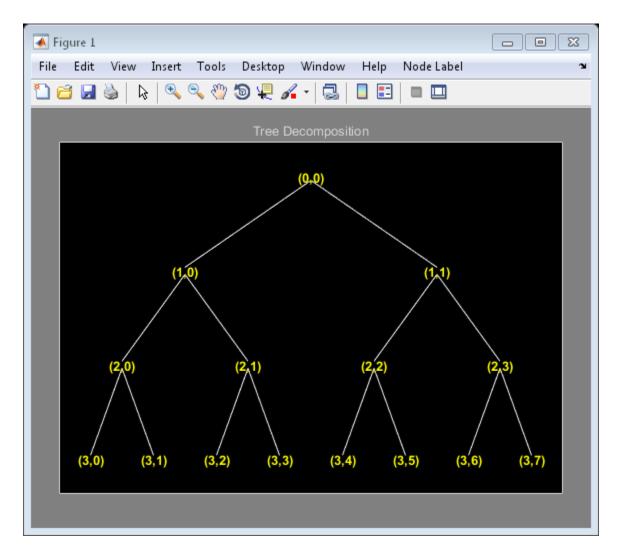

```
N must be a column vector of integers (N \ge 0).
```

```
Note that [D,P] = ind2depo(ORD,[D P]).
```

Depth and Position in Wavelet Packet Tree

Create a binary wavelet packet tree with three levels.

```
Ord = 2;
Lev = 3;
T = ntree(Ord,Lev);
Plot the binary wavelet packet tree.
plot(T)
```

Obtain the indices of the nodes in linear order.

```
idx = allnodes(T);
```

Conver the indices to depth-position format.

```
[depth,pos] = ind2depo(Ord,idx);
table(depth,pos)
```

ans =

intwave

Integrate wavelet function psi (ψ)

Syntax

```
[INTEG,XVAL] = intwave('wname',PREC)
[INTDEC,XVAL,INTREC] = intwave('wname',PREC)
[INTEG,XVAL] = intwave('wname',PREC,0)
[INTEG,XVAL] = intwave('wname',PREC,0)
[INTEG,XVAL] = intwave('wname')
[INTEG,XVAL] = intwave('wname',8)
intwave('wname',IN2,IN3), PREC = max(IN2,IN3)
intwave('wname',0)
intwave('wname',8,IN3)
intwave('wname')
intwave('wname',8)
```

Description

```
[INTEG, XVAL] = intwave('wname', PREC) computes the integral, INTEG, of the wavelet function \psi (from -\infty to XVAL values): \int_{-\infty}^{x} \psi(y) dy for x in XVAL.
```

The function ψ is approximated on the 2^{PREC} points grid XVAL where *PREC* is a positive integer. 'wname' is a string containing the name of the wavelet ψ (see wfilters for more information).

Output argument INTEG is a real or complex vector depending on the wavelet type.

For biorthogonal wavelets,

[INTDEC, XVAL, INTREC] = intwave('wname', PREC) computes the integrals, INTDEC and INTREC, of the wavelet decomposition function ψ_{dec} and the wavelet reconstruction function ψ_{rec} .

```
[INTEG,XVAL] = intwave('wname',PREC) is equivalent to [INTEG,XVAL] =
intwave('wname',PREC,0).
```

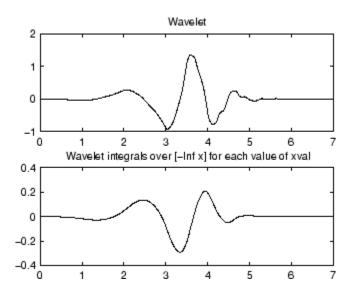

```
[INTEG,XVAL] = intwave('wname') is equivalent to [INTEG,XVAL] =
intwave('wname',8).

When used with three arguments intwave('wname',IN2,IN3), PREC =
max(IN2,IN3) and plots are given.

When IN2 is equal to the special value 0, intwave('wname',0) is equivalent to intwave('wname',8,IN3).

intwave('wname') is equivalent to intwave('wname',8).

intwave is used only for continuous analysis (see cwt for more information).
```

More About

Algorithms

First, the wavelet function is approximated on a grid of 2^{PREC} points using wavefun. A piecewise constant interpolation is used to compute the integrals using Cumsum.

wavefun

isnode

Existing node test

Syntax

```
R = isnode(T, N)
```

Description

isnode is a tree-management utility.

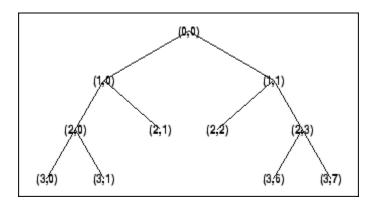

```
R = isnode(T, N) returns 1's for nodes N, which exist in the tree T, and 0's for others.
```

N can be a column vector containing the indices of nodes or a matrix, that contains the depths and positions of nodes.

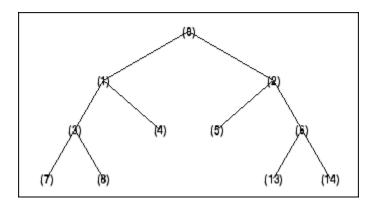

In the last case, N(i,1) is the depth of the i-th node and N(i,2) is the position of the i-th node.

The nodes are numbered from left to right and from top to bottom. The root index is 0.

```
% Create initial tree.
ord = 2;
t = ntree(ord,3); % binary tree of depth 3.
t = nodejoin(t,5);

iswt

Inverse discrete stationary wavelet transform 1-D

Syntax

```
X = iswt(SWC, 'wname')
X = iswt(SWA,SWD, 'wname')
X = iswt(SWA(end,:),SWD, 'wname')
X = iswt(SWC,Lo_R,Hi_R)
X = iswt(SWA,SWD,Lo_R,Hi_R)
X = iswt(SWA(end,:),SWD,Lo_R,Hi_R)
```

Description

iswt performs a multilevel 1-D stationary wavelet reconstruction using either a specific orthogonal wavelet ('wname', see wfilters for more information) or specific reconstruction filters (Lo_R and Hi_R).

```
X = iswt(SWC, 'wname') or X = iswt(SWA, SWD, 'wname') or X = iswt(SWA(end,:), SWD, 'wname') reconstructs the signal X based on the multilevel stationary wavelet decomposition structure SWC or [SWA, SWD] (see SWt for more information).
```

```
X = iswt(SWC, Lo_R, Hi_R) or X = iswt(SWA, SWD, Lo_R, Hi_R) or X = iswt(SWA(end,:), SWD, Lo_R, Hi_R) reconstruct as above, using filters that you specify.
```

- Lo R is the reconstruction low-pass filter.
- Hi_R is the reconstruction high-pass filter.

 Lo_R and Hi_R must be the same length.

```
% Load original 1D signal.
```

```
load noisbloc; s = noisbloc;
% Perform SWT decomposition at level 3 of s using db1.
swc = swt(s,3,'db1');
% Second usage.

iswt2

Inverse discrete stationary wavelet transform 2-D

Syntax

```
X = iswt2(SWC, 'wname')
X = iswt2(A,H,V,D,wname)
X = iswt2(A(:,:,end),H,V,D,'wname')
X = iswt2(SWC,Lo_R,Hi_R)
X = iswt2(A,H,V,D,Lo_R,Hi_R)
X = iswt2(A(:,:,end),H,V,D,Lo_R,Hi_R)
```

Description

iswt2 performs a multilevel 2-D stationary wavelet reconstruction using either a specific orthogonal wavelet ('wname' see wfilters for more information) or specific reconstruction filters (Lo R and Hi R).

```
X = iswt2(SWC, 'wname') \text{ or } X = iswt2(A,H,V,D,wname) \text{ or } X = iswt2(A(:,:,end),H,V,D,'wname') \text{ reconstructs the signal } X, \text{ based on the multilevel stationary wavelet decomposition structure SWC or [A,H,V,D] (see Swt2).}
```

```
X = iswt2(SWC, Lo_R, Hi_R) or X = iswt2(A, H, V, D, Lo_R, Hi_R) or X = iswt2(A(:,:,end), H, V, D, Lo_R, Hi_R) reconstructs as in the previous syntax, using filters that you specify:
```

- · Lo_R is the reconstruction low-pass filter.
- Hi_R is the reconstruction high-pass filter.

Lo_R and Hi_R must be the same length.

```
% Load original image.
load nbarb1;
```

```
% Perform SWT decomposition
% of X at level 3 using sym4.
swc = swt2(X,3,'sym4');
% Second usage.
[ca,chd,cvd,cdd] = swt2(X,3,'sym4');
% Reconstruct s from the stationary wavelet
% decomposition structure swc.
a0 = iswt2(swc, 'sym4');
% Second usage.
a0 = iswt2(ca,chd,cvd,cdd,'sym4');
% Check for perfect reconstruction.
err = max(max(abs(X-a0)))
ans =
  2.3482e-010
errbis = max(max(abs(X-a0bis)))
ans =
  2.3482e-010
```

More About

Tips

If SWC or (cA,cH,cV,cD) are obtained from an indexed image analysis or a truecolor image analysis, then X is an m-by-n matrix or an m-by-n-by-3 array, respectively.

For more information on image formats, see the image and imfinfo reference pages.

laurmat

Laurent matrices constructor

Syntax

```
M = laurmat(V)
```

Description

M = laurmat(V) returns the Laurent matrix object M associated with V which can be a cell array (at most two dimensional) of Laurent polynomials (see laurpoly) or an ordinary matrix.

Examples

```
% Define Laurent matrices.
M1 = laurmat(eye(2,2))
```

$$M1 = \begin{vmatrix} 1 & 0 & | \\ | & & | \\ | & & | \\ | & & | \\ | & 0 & 1 & | \end{vmatrix}$$

Z = laurpoly(1,1);
M2 = laurmat({1 Z;0 1})

% Calculus on Laurent polynomials.

$$P = M1 * M2$$

$$d = det(P)$$

$$d(z) = 1$$

laurpoly

laurpoly

Laurent polynomials constructor

Syntax

```
P = laurpoly(C,d)
P = laurpoly(C,'dmin',d)
P = laurpoly(C,'dmax',d)
P = laurpoly(C,d)
```

Description

P = laurpoly(C,d) returns a Laurent polynomial object. C is a vector whose elements are the coefficients of the polynomial P and d is the highest degree of the monomials of P.

If **m** is the length of the vector **C**, **P** represents the following Laurent polynomial:

```
P(z) = C(1)*z^d + C(2)*z^(d-1) + ... + C(m)*z^(d-m+1)
```

P = laurpoly(C, 'dmin', d) specifies the lowest degree instead of the highest degree of monomials of P. The corresponding output P represents the following Laurent polynomial:

```
P(z) = C(1)*z^{(d+m-1)} + ... + C(m-1)*z^{(d+1)} + C(m)*z^{d}
P = laurpoly(C, 'dmax', d) \text{ is equivalent to } P = laurpoly(C, d).
```

```
% Define Laurent polynomials.
P = laurpoly([1:3],2);
P = laurpoly([1:3],'dmax',2)
P(z) = + z^(+2) + 2*z^(+1) + 3
P = laurpoly([1:3],'dmin',2)
```

$$P(z) = + z^{(+4)} + 2*z^{(+3)} + 3*z^{(+2)}$$

% Calculus on Laurent polynomials.
 $Z = laurpoly(1,1)$
 $Z(z) = z^{(+1)}$
 $Q = Z*P$
 $Q(z) = + z^{(+5)} + 2*z^{(+4)} + 3*z^{(+3)}$
 $R = Z^{1} - Z^{-1}$
 $R(z) = + z^{(+1)} - z^{(-1)}$

leaves

Determine terminal nodes

Syntax

```
N = leaves(T)
[N,K] = leaves(T,'sort')
N = leaves(T,'dp')
[N,K] = leaves(T,'sortdp')
[N,K] = leaves(T,'sdp')
```

Description

N = leaves(T) returns the indices of terminal nodes of the tree T where N is a column vector.

The nodes are ordered from left to right as in tree *T*.

```
[N,K] = leaves(T, 's') \text{ or } [N,K] = leaves(T, 'sort') \text{ returns sorted indices. } M = N(K) \text{ are the indices reordered as in tree } T, \text{ from left to right.}
```

N = leaves(T, 'dp') returns a matrix N, which contains the depths and positions of terminal nodes.

N(i,1) is the depth of the i-th terminal node, and N(i,2) is the position of the i-th terminal node.

```
[N,K] = leaves(T, 'sortdp') \text{ or } [N,K] = leaves(T, 'sdp') \text{ returns sorted nodes.}
```

```
% Create initial tree.
ord = 2;
t = ntree(ord,3); % binary tree of depth 3.
t=nodejoin(t,5);
t=nodejoin(t,4);

liftfilt

Apply elementary lifting steps on quadruplet of filters

Syntax

```
[LoDN,HiDN,LoRN,HiRN] = liftfilt(LoD,HiD,LoR,HiR,ELS)
liftfilt(LoD,HiD,LoR,HiR,ELS,TYPE,VALUE)
```

Description

[LoDN, HiDN, LoRN, HiRN] = liftfilt(LoD, HiD, LoR, HiR, ELS) returns the four filters LoDN, HiDN, LoRN, and HiRN obtained by an elementary lifting step (ELS) starting from the four filters LoD, HiD, LoR, and HiR. The four input filters verify the perfect reconstruction condition.

ELS is a structure such that

- TYPE = ELS.type contains the type of the elementary lifting step. The valid values for TYPE are 'p' (primal) or 'd' (dual).
- VALUE = ELS.value contains the Laurent polynomial T associated with the elementary lifting step (see laurpoly). If VALUE is a vector, the associated Laurent polynomial T is equal to laurpoly(VALUE, 0).

In addition, ELS may be a scaling step. In that case, TYPE is equal to 'S' (scaling) and VALUE is a scalar different from zero.

liftfilt(LoD, HiD, LoR, HiR, ELS, TYPE, VALUE) gives the same outputs.

```
Note If TYPE = 'p', HiD and LoR are unchanged.

If TYPE = 'd', LoD and HiR are unchanged.

If TYPE = 's', the four filters are changed.

If ELS is an array of elementary lifting steps, liftfilt(...,ELS) performs each step successively.
```

liftfilt(...,FLAGPLOT) plots the successive biorthogonal pairs—scaling function and wavelet.

Examples

```
% Get Haar filters.
[LoD,HiD,LoR,HiR] = wfilters('haar');
% Lift the Haar filters.
twoels(1) = struct('type','p','value',...
laurpoly([0.125 -0.125],0));
twoels(2) = struct('type','p','value',...
laurpoly([0.125 -0.125],1));
[LoDN,HiDN,LoRN,HiRN] = liftfilt(LoD,HiD,LoR,HiR,twoels);
% The biorthogonal wavelet bior1.3 is obtained up to
% an unsignificant sign.
[LoDB,HiDB,LoRB,HiRB] = wfilters('bior1.3');
samewavelet = ...
isequal([LoDB,HiDB,LoRB,HiRB],[LoDN,-HiDN,LoRN,HiRN])
samewavelet =
```

laurpoly

liftwave

Lifting schemes

Syntax

```
LS = liftwave(WNAME)
LS = liftwave(WNAME, 'Int2Int')
```

Description

LS = liftwave(WNAME) returns the lifting scheme associated with the wavelet specified by WNAME. LS is a structure, not an integer, and used by lwt, ilwt, lwt2, etc.

LS = liftwave(WNAME, 'Int2Int') performs an integer to integer wavelet transform. Using 'Int2Int' produces an LS such that when you use [CA,CD] = lwt(X,LS) or Y = lwt(X,LS) and X is a vector of integers, the resulting CA, CD, and Y are vectors of integers. If you omit 'Int2Int' then lwt produces vectors of real numbers.

The valid values for WNAME are

WNAME Values	Comments
'lazy'	A "lazy" wavelet is a second-generation wavelet and is not a true mathematical wavelet.
'haar'	Same as 'db1', 'bior1.1', and 'cdf1.1'
'db1', 'db2', 'db3', 'db4', 'db5', 'db6', 'db7', 'db8'	'db2' same as 'sym2', 'db3', and 'sym4'
'sym2', 'sym3', 'sym4', 'sym5', 'sym6', 'sym7', 'sym8'	
Cohen-Daubechies-Feauveau wavelets 'cdf1.1','cdf1.3','cdf1.5' 'cdf3.1','cdf3.3','cdf3.5' 'cdf5.1','cdf5.3','cdf5.5' 'cdf2.2','cdf2.4','cdf2.6'	'cdfX.Y' same as 'biorX.Y' except for bior4.4 and bior5.5.

WNAME Values	Comments
'cdf4.2','cdf4.4','cdf4.6' 'cdf6.2','cdf6.4','cdf6.6'	
'biorX.Y'	See waveinfo
'rbioX.Y'	Reverse of 'biorX.Y'. See waveinfo
'bs3'	Same as 'cdf4.2'
'rbs3'	Reverse of 'bs3'
'9.7'	Same as 'bior4.4'
'r9.7'	Reverse of '9.7'

For more information about lifting schemes, see lsinfo.

Examples

```
% Start from the db2 wavelet and get the
% corresponding lifting scheme.
lsdb2 = liftwave('db2');
% Visualize the obtained lifting scheme.
displs(lsdb2);
1sdb2 = {...}
' d '
                [ -1.73205081]
                                             [0]

laurpoly

localmax

Identify and chain local maxima

Syntax

```
[lmaxima,indices] = localmax(inputmatrix)
[lmaxima,indices] = localmax(inputmatrix,initrow)
[lmaxima,indices] = localmax(inputmatrix,initrow,regflag)
```

Description

[lmaxima,indices] = localmax(inputmatrix) identifies and chains the local maxima in the rows of inputmatrix.

[lmaxima,indices] = localmax(inputmatrix,initrow) initializes the chaining of local maxima beginning with row initrow. If there are no local maxima in initrow, all rows in lmaxima with indices less than initrow consist of only zeros.

[lmaxima,indices] = localmax(inputmatrix,initrow,regflag) replaces initrow of inputmatrix with the level-5 approximation (scaling) coefficients obtained with the sym4 wavelet.

Input Arguments

inputmatrix

inputmatrix is a matrix of real or complex numbers. Most often, inputmatrix is a matrix of continuous wavelet transform (CWT) coefficients, and you use localmax to identify maxima lines. localmax operates on the absolute values of inputmatrix.

initrow

Initialization row for chaining local maxima. The chaining algorithm begins at initrow and decrements the row index by 1 until the first row of the matrix is reached. By specifying initrow, you can exclude rows from the chaining algorithm.

Default: size(inputmatrix,1)

regflag

Regularization flag. If you set regflag to true, the row of inputmatrix corresponding to initrow is replaced by the level-5 approximation (scaling) coefficients obtained with the sym4 wavelet.

Default: true

Output Arguments

lmaxima

Matrix with local maxima chains. lmaxima only has nonzero entries at the locations of local maxima in the absolute values of inputmatrix. Denote the row index of lmaxima by R. You can determine the value of lmaxima at a local maximum in row R as follows:

- If R>initRow, the value of lmaxima at a local maximum is 1.
- If R=initRow, the value of lmaxima at a local maximum is the column index in row R.
- If R<initRow, the value of lmaxima at a local maximum in row R is the column index of the nearest local maximum in row R+1.

To illustrate this, if inputmatrix is:

3	2	5	3
4	6	3	2
4	4	7	4
4	6	2	2

lmaxima with initRow = 4 and regflag = false is:

0	0	2	0
0	3	0	0
0	0	2	0
0	2	0	0

lmaxima with initRow = 3 and regflag = false is:

0 0 2 0

```
0 3 0 0
0 0 3 0
0 1 0 0
```

• If the local maximum in row R lies between two local maxima in row R+1, the value of the local maximum in row R is the higher column index in row R+1.

To illustrate this, if inputmatrix is:

0

```
0
     0
           1
                        1
                              0
                                    0
lmaxima with initRow = 2 and regflag = false is:
     0
           0
                        0
                              0
                                    0
     0
           2
                  0
                        4
                              0
                                    0
lmaxima with initRow = 1 and regflag = false is:
                  3
                              0
```

indices

0

Linear indices of the nonzero values of lmaxima. Use ind2sub to convert the linear indices to matrix row and column indices.

0

Examples

Construct a 4-by-4 matrix with local maxima at the following row-column indices: (4,2), (3,3), (2,2), and (1,3). Set initrow to 4 and regflag to false.

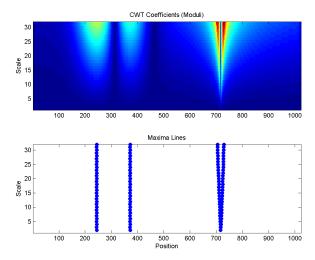

Because localmax operates on the absolute values of inputmatrix, setting inputmatrix(4,2) = -inputmatrix(4,2) produces an identical lmaxima.

```
inputmatrix(4,2) = -inputmatrix(4,2);
```

```
[lmaxima1,indices1] = localmax(inputmatrix,4,false);
isequal(lmaxima,lmaxima1)
```

Determine the local maxima from the CWT of the cuspamax signal with the Haar wavelet. Plot the CWT coefficient moduli and the maxima lines.

```
load cuspamax;
x = 1:length(cuspamax);
scales = 1:32;
cfs = cwt(cuspamax,scales,'haar');
[lmaxima,indices] = localmax(cfs,[],false);
[iRow,iCol] = find(lmaxima);
subplot(211);
imagesc(abs(cfs)); axis xy;
axis([1 1024 1 32]);
ylabel('Scale'); title('CWT Coefficients (Moduli)');
subplot(212);
plot(x(iCol),scales(iRow),'marker','o','markerfacecolor',[0 0 1],...
    'linestyle','none');
xlabel('Position'); ylabel('Scale'); title('Maxima Lines');
axis([1 1024 1 32]);
```

Introduced in R2008a

ls2filt

Transform lifting scheme to quadruplet of filters

Syntax

```
[LoD, HiD, LoR, HiR] = ls2filt(LS)
```

Description

[LoD, HiD, LoR, HiR] = 1s2filt(LS) returns the four filters LoD, HiD, LoR, and HiR associated with the lifting scheme LS.

```
% Start from the db2 wavelet and get the
% corresponding lifting scheme.
LS = liftwave('db2')
LS =
    ' d '
                 [ -1.7321]

Isinfo

Lifting schemes information

Syntax

lsinfo

Description

lsinfo displays the following information about lifting schemes. A lifting scheme LS is a N x 3 cell array. The N-1 first rows of the array are elementary lifting steps (ELS). The last row gives the normalization of LS.

Each ELS has this format:

```
{type, coefficients, max_degree}
```

where type is 'p' (primal) or 'd' (dual), coefficients is a vector C of real numbers defining the coefficients of a Laurent polynomial P described below, and max_degree is the highest degree d of the monomials of P.

The Laurent polynomial P is of the form

$$P(z) = C(1)*z^{\wedge}d + C(2)*z^{\wedge}(d-1) + \dots + C(m)*z^{\wedge}(d-m+1)$$

The lifting scheme LS is such that for

```
k = 1:N-1, LS\{k,:\} is an ELS, where
```

 $LS\{k,1\}$ is the lifting type 'p' (primal) or 'd' (dual).

 $LS\{k,2\}$ is the corresponding lifting filter.

 $LS\{k,3\}$ is the highest degree of the Laurent polynomial corresponding to the filter $LS\{k,2\}$.

 $LS{N,1}$ is the primal normalization (real number).

LS{N,2} is the dual normalization (real number).

 $LS{N,3}$ is not used.

Usually, the normalizations are such that $LS\{N,1\}*LS\{N,2\} = 1$.

For example, the lifting scheme associated with the wavelet db1 is

lwt

1-D lifting wavelet transform

Syntax

```
[CA,CD] = lwt(X,W)
X_InPlace = lwt(X,W)
lwt(X,W,LEVEL)
X_InPlace = lwt(X,W,LEVEL,'typeDEC',typeDEC)
[CA,CD] = lwt(X,W,LEVEL,'typeDEC',typeDEC)
```

Description

1Wt performs a 1-D lifting wavelet decomposition with respect to a particular lifted wavelet that you specify.

[CA,CD] = lwt(X,W) computes the approximation coefficients vector CA and detail coefficients vector CD, obtained by a lifting wavelet decomposition, of the vector X. W is a lifted wavelet name (see liftwave).

X_InPlace = lwt(X,W) computes the approximation and detail coefficients. These coefficients are stored in place:

```
CA = X_{InPlace(1:2:end)} and CD = X_{InPlace(2:2:end)}
```

lwt(X, W, LEVEL) computes the lifting wavelet decomposition at level LEVEL.

X_InPlace = lwt(X,W,LEVEL, 'typeDEC', typeDEC) or [CA,CD] = lwt(X,W,LEVEL, 'typeDEC', typeDEC) with typeDEC = 'w' or 'wp' computes the wavelet or the wavelet packet decomposition using lifting, at level LEVEL.

Instead of a lifted wavelet name, you may use the associated lifting scheme LS: lwt(X,LS,...) instead of lwt(X,W,...).

For more information about lifting schemes, see lsinfo.

Examples

```
% Start from the Haar wavelet and get the
% corresponding lifting scheme.
lshaar = liftwave('haar');
% Add a primal ELS to the lifting scheme.
els = \{'p', [-0.125 \ 0.125], 0\};
lsnew = addlift(lshaar,els);
% Perform LWT at level 1 of a simple signal.
x = 1:8;
[cA,cD] = lwt(x,lsnew)
cA =
    1.9445
             4.9497
                      7.7782
                                 10.6066
cD =
    0.7071
             0.7071
                        0.7071
                                  0.7071
% Perform integer LWT of the same signal.
lshaarInt = liftwave('haar','int2int');
lsnewInt = addlift(lshaarInt,els);
[cAint,cDint] = lwt(x,lsnewInt)
cAint =
     1
           3
                5
                   7
cDint =
     1
         1 1
                     1
```

More About

Algorithms

This function uses the polyphase algorithm.

1wt reduces to dwt with zero-padding extension mode and without extra-coefficients.

lwt2

2-D lifting wavelet transform

Syntax

```
[CA,CH,CV,CD] = lwt2(X,W)
X_InPlace = lwt2(X,LS)
lwt2(X,W,LEVEL)
X_InPlace = lwt2(X,W,LEVEL,'typeDEC',typeDEC)
[CA,CH,CV,CD] = LWT2(X,W,LEVEL,'typeDEC',typeDEC)
```

Description

1wt2 performs a 2-D lifting wavelet decomposition with respect to a particular lifted wavelet that you specify.

[CA, CH, CV, CD] = 1wt2(X, W) computes the approximation coefficients matrix CA and detail coefficients matrices CH, CV, and CD, obtained by a lifting wavelet decomposition, of the matrix X. W is a lifted wavelet name (see liftwave).

X_InPlace = lwt2(X,LS) computes the approximation and detail coefficients. These coefficients are stored in place:

```
    CA = X_InPlace(1:2:end,1:2:end)
    CH = X_InPlace(2:2:end,1:2:end)
    CV = X_InPlace(1:2:end,2:2:end)
    CD = X InPlace(2:2:end,2:2:end)
```

lwt2(X, W, LEVEL) computes the lifting wavelet decomposition at level LEVEL.

X_InPlace = lwt2(X,W,LEVEL, 'typeDEC', typeDEC) or [CA,CH,CV,CD] = LWT2(X,W,LEVEL, 'typeDEC', typeDEC) with typeDEC = 'w' or 'wp' computes the wavelet or the wavelet packet decomposition using lifting, at level LEVEL.

Instead of a lifted wavelet name, you may use the associated lifting scheme LS: lwt2(X,LS,...) instead of LWT2(X,W,...).

For more information about lifting schemes, see lsinfo.

More About

Tips

When X represents an indexed image, X, as well as the output arrays cA,cH,cV,cD, or X_InPlace are m-by-n matrices. When X represents a truecolor image, it is an m-by-n-by-3 array, where each m-by-n matrix represents a red, green, or blue color plane concatenated along the third dimension.

For more information on image formats, see the image and imfinfo reference pages .

Algorithms

This function implements the polyphase algorithm.

1wt reduces to dwt with zero-padding extension mode and without extra-coefficients.

lwtcoef

Extract or reconstruct 1-D LWT wavelet coefficients

Syntax

```
Y = lwtcoef(TYPE, XDEC, LS, LEVEL, LEVEXT)
Y = lwtcoef(TYPE, XDEC, W, LEVEL, LEVEXT)
```

Description

Y = lwtcoef(TYPE, XDEC, LS, LEVEL, LEVEXT) returns the coefficients or the reconstructed coefficients of level LEVEXT, extracted from XDEC, the LWT decomposition at level LEVEL obtained with the lifting scheme LS.

The valid values for TYPE are

TYPE Values	Description
'a'	Approximations
'd'	Details
'ca'	Coefficients of approximations
'cd'	Coefficients of details

Y = lwtcoef(TYPE, XDEC, W, LEVEL, LEVEXT) returns the same output using W, which is the name of a lifted wavelet.

Examples

```
% Start from the Haar wavelet and get the
% corresponding lifting scheme.
lshaar = liftwave('haar');
% Add a primal ELS to the lifting scheme.

ilwt2 | lwt2

Introduced before R2006a

mdwtcluster

Multisignals 1-D clustering

Syntax

```
S = mdwtcluster(X)
S = mdwtcluster(X, 'PropName1', PropVal1, 'PropName2', PropVal2,...)
```

Description

S = mdwtcluster(X) constructs clusters from a hierarchical cluster tree. The input matrix X is decomposed in row direction using the DWT function with the haar wavelet and the maximum allowed level.

S = mdwtcluster(X, 'PropName1', PropVal1, 'PropName2', PropVal2,...) allows you to modify some properties. The valid choices for *PropName* are:

Note: mdwtcluster requires the Statistics and Machine Learning ToolboxTM

	,
'dirDec'	'r' (row) or 'c' (column). Default value is 'r'.
'level'	Level of the DWT decomposition. Default value is: level=fix(log2(size(X,d))) where d=1 or d=2, depending on the dirDec value.
'wname'	Wavelet name used for DWT. Default value is 'haar'.
'dwtEXTM'	DWT extension mode (see dwtmode).
'pdist'	See Statistics and Machine Learning Toolbox pdist function. Default value is 'euclidean'.
'linkage'	See Statistics and Machine Learning Toolbox linkage function. Default value is 'ward'.
'maxclust'	Number of clusters. Default value is 6. The input variable can be a vector.

'lst2clu'	Cell array that contains the list of data to classify.
	If N is the level of decomposition, the allowed name values for the cells are:
	• 's' — Signal
	· 'aj' — Approximation at level j
	· 'dj' — Detail at level j
	· 'caj' — Coefficients of approximation at level j
	· 'cdj' — Coefficients of detail at level j
	Default value is { 's'; 'ca1';; 'caN'}.

The output structure S is such that for each partition j:

S.Idx(:,j)	Contains the cluster numbers obtained from the hierarchical cluster tree (see cluster in the Statistics and Machine Learning Toolbox software).
S.Incons(:,j)	Contains the inconsistent values of each non-leaf node in the hierarchical cluster tree (see Statistics and Machine Learning Toolbox software function inconsistent).
S.Corr(j)	Contains the cophenetic correlation coefficients of the partition (see Statistics and Machine Learning Toolbox software function cophenet).

Note If maxclustVal is a vector, then IdxCLU is a multidimensional array such that IdxCLU(:,j,k) contains the cluster numbers obtained from the hierarchical cluster tree for k clusters.

Examples

```
load elecsig10
lst2clu = {'s','ca1','ca3','ca6'};
% Compute the structure resulting from multisignal clustering
S = mdwtcluster(signals,'maxclust',4,'lst2clu',lst2clu)
```

```
S =
    IdxCLU: [70x4 double]
    Incons: [69x4 double]
      Corr: [0.7920 0.7926 0.7947 0.7631]
% Retrieve indices of clusters
IdxCLU = S.IdxCLU;
% Plot the first cluster
plot(signals(IdxCLU(:,1)==1,:)','r');
hold on;
% Plot the third clustering
plot(signals(IdxCLU(:,1)==3,:)','b')
% Check the equality of partitions
equalPART = isequal(IdxCLU(:,1),IdxCLU(:,3))
equalPART =
     1
% So we can see that we obtain the same partitions using
```

% coefficents of approximation at level 3 instead of original % signals. Much less information is then used.

mdwtdec | wavedec

Introduced in R2008a

mdwtdec

Multisignal 1-D wavelet decomposition

Syntax

```
DEC = mdwtdec(DIRDEC,X,LEV,WNAME)
DEC = mdwtdec(DIRDEC,X,LEV,LoD,HiD,LoR,HiR)
DEC = mdwtdec(...,'mode',EXTMODE)
```

Description

DEC = mdwtdec(DIRDEC, X, LEV, WNAME) returns the wavelet decomposition at level LEV of each row (if DIRDEC = 'r') or each column (if DIRDEC = 'c') of matrix X, using the wavelet WNAME.

The output DEC is a structure with the following fields:

'dirDec'	Direction indicator: 'r' (row) or 'C' (column)
'level'	Level of the DWT decomposition
'wname'	Wavelet name
'dwtFilters'	Structure with four fields LOD, HiD, LOR and HiR
'dwtEXTM'	DWT extension mode (see dwtmode)
'dwtShift'	DWT shift parameter (0 or 1)
'dataSize'	Size of X
'ca'	Approximation coefficients at level LEV
'cd'	Cell array of detail coefficients, from level 1 to level LEV

Coefficients cA and $cD\{k\}$ (for k = 1 to LEV) are matrices and are stored in rows if DIRDEC = 'r' or in columns if DIRDEC = 'c'.

DEC = mdwtdec(DIRDEC,X,LEV,LoD,HiD,LoR,HiR) uses the four filters instead of the wavelet name.

 $\label{eq:decomposition} \begin{tabular}{ll} DEC = mdwtdec(..., 'mode', EXTMODE) computes the wavelet decomposition with the EXTMODE extension mode that you specify (see dwtmode for the valid extension modes). \end{tabular}$

Examples

```
% Load original 1D-multisignal.
load thinker
% Perform a decomposition at level 2 using wavelet db2.
dec = mdwtdec('r', X, 2, 'db2')
dec =
        dirDec: 'r'
         level: 2
         wname: 'db2'
    dwtFilters: [1x1 struct]
       dwtEXTM: 'sym'
      dwtShift: 0
      dataSize: [192 96]
            ca: [192x26 double]
            cd: {[192x49 double] [192x26 double]}
% Compute the associated filters of db2 wavelet.
[LoD, HiD, LoR, HiR] = wfilters('db2');
% Perform a decomposition at level 2 using filters.
decBIS = mdwtdec('r',X,2,LoD,HiD,LoR,HiR)
decBIS =
        dirDec: 'r'
         level: 2
         wname: ''
    dwtFilters: [1x1 struct]
       dwtEXTM: 'sym'
      dwtShift: 0
      dataSize: [192 96]
            ca: [192x26 double]
            cd: {[192x49 double] [192x26 double]}
```

mdwtdec | wavedec

Introduced in R2007a

mdwtrec

Multisignal 1-D wavelet reconstruction

Syntax

```
X = mdwtrec(DEC)
X = mdwtrec(DEC,IDXSIG)
Y = mdwtrec(DEC,TYPE,LEV)
A = mdwtrec(DEC,'a')
A = mdwtrec(DEC,'a',LEVDEC)
D = mdwtrec(DEC,'d')
CA = mdwtrec(DEC,'ca',LEVDEC)
CA = mdwtrec(DEC,'ca',LEVDEC)
CD = mdwtrec(DEC,'cd',MODE)
CFS = mdwtrec(DEC,'cfs',MODE)
Y = mdwtrec(...,IDXSIG)
```

Description

X = mdwtrec(DEC) returns the original matrix of signals, starting from the wavelet decomposition structure DEC (see mdwtdec).

X = mdwtrec(DEC, IDXSIG) reconstructs the signals whose indices are given by the vector IDXSIG.

Y = mdwtrec(DEC, TYPE, LEV) extracts or reconstructs the detail or approximation coefficients at level LEV depending on the TYPE value. The maximum value for LEV is LEVDEC = DEC.level.

When TYPE is equal to:

- 'cd' or 'ca', coefficients of level LEV are extracted.
- 'd' or 'a', coefficients of level LEV are reconstructed.
- 'a' or 'ca', LEV must be such that $0 \le LEV \le LEVDEC$.
- 'd' or 'cd', LEV must be such that $1 \le LEV \le LEVDEC$.

```
A = mdwtrec(DEC, 'a') is equivalent to A = mdwtrec(DEC, 'a', LEVDEC).

D = mdwtrec(DEC, 'd') returns a matrix containing the sum of all the details, so that X = A + D.

CA = mdwtrec(DEC, 'ca') is equivalent to CA = mdwtrec(DEC, 'ca', LEVDEC).

CD = mdwtrec(DEC, 'cd', MODE) returns a matrix containing all the detail coefficients.

CFS = mdwtrec(DEC, 'cfs', MODE) returns a matrix containing all the coefficients.

For MODE = 'descend' the coefficients are concatened from level LEVDEC to level 1 and MODE = 'descend' concatenates from level 1 to level LEVDEC). The default is MODE = 'descend'. The concatenation is made row-wise if DEC.dirDEC = 'r' or column-wise if DEC.dirDEC = 'c'.
```

Y = mdwtrec(..., IDXSIG) extracts or reconstructs the detail or the approximation

coefficients for the signals whose indices are given by the vector IDXSIG.

Examples

```
% Load original 1D-multisignal.
load thinker
% Perform a decomposition at level 2 using wavelet db2.
dec = mdwtdec('r', X, 2, 'db2');
% Reconstruct the original matrix of signals, starting from
% the wavelet decomposition structure dec.
XR = mdwtrec(dec);
% Compute the reconstruction error.
errREC = max(max(abs(X-XR)))
errREC =
  2.1026e-010
% Reconstruct the original signal 31, the corresponding
% approximation at level 2, details at levels 1 and 2.
Y = mdwtrec(dec, 31);
A2 = mdwtrec(dec, 'a', 2, 31);
D2 = mdwtrec(dec, 'd', 2, 31);
```

```
D1 = mdwtrec(dec,'d',1,31);
% Compute the reconstruction error for signal 31.
errREC = max(abs(Y-A2-D2-D1))
errREC =
  6.8390e-014
```

mdwtdec | waverec

Introduced in R2007a

measerr

Approximation quality metrics

Syntax

```
[PSNR,MSE,MAXERR,L2RAT] = measerr(X,XAPP)
[...] = measerr(...,BPS)
```

Description

[PSNR, MSE, MAXERR, L2RAT] = measerr(X, XAPP) returns the peak signal-to-noise ratio, PSNR, mean square error, MSE, maximum squared error, MAXERR, and ratio of squared norms, L2RAT, for an input signal or image, X, and its approximation, XAPP.

[...] = measerr(...,BPS) uses the bits per sample, BPS, to determine the peak signal-to-noise ratio.

Input Arguments

Χ

X is a real-valued signal or image.

XAPP

XAPP is a real-valued signal or image approximation with a size equal to that of the input data, X.

BPS

BPS is the number of bits per sample in the data.

Default: 8

Output Arguments

PSNR

PSNR is the peak signal-to-noise ratio in decibels (dB). The PSNR is only meaningful for data encoded in terms of bits per sample, or bits per pixel. For example, an image with 8 bits per pixel contains integers from 0 to 255.

MSE

The mean square error (MSE) is the squared norm of the difference between the data and the approximation divided by the number of elements.

MAXERR

MAXERR is the maximum absolute squared deviation of the data, X, from the approximation, XAPP.

L2RAT

L2RAT is the ratio of the squared norm of the signal or image approximation, XAPP, to the input signal or image, X.

Examples

Approximate an image and calculate approximation quality metrics.

```
load woman;
Xapp = X;
Xapp(X<=50) = 1;
[psnr,mse,maxerr,L2rat] = measerr(X,Xapp);
figure; colormap(map);
subplot(1,2,1); image(X);
subplot(1,2,2); image(Xapp);</pre>
```

Measure approximation quality in an RGB image.

```
X = imread('africasculpt.jpg');
Xapp = X;
Xapp(X<=100) = 1;
[psnr,mse,maxerr,L2rat] = measerr (X,Xapp)</pre>
```

```
figure;
subplot(1,2,1); image(X);
subplot(1,2,2); image(Xapp);
```

More About

Peak Signal to Noise Ratio (PSNR)

The following equation defines the PSNR:

$$20\log_{10}(\frac{2^B-1}{\sqrt{MSE}})$$

where MSE represents the mean square error and B represents the bits per sample.

Mean Square Error (MSE)

The mean square error between a signal or image, X, and an approximation, Y, is the squared norm of the difference divided by the number of elements in the signal or image:

$$\frac{||X-Y||^2}{N}$$

References

Huynh-Thu, Q.Scope of validity of PSNR in image/video quality assessment, Electronics Letters, 44, 2008, pp. 800–801.

wden | wdencmp

Introduced in R2010b

mexihat

Mexican hat wavelet

Syntax

```
[PSI,X] = mexihat(LB,UB,N)
```

Description

[PSI,X] = mexihat(LB,UB,N) returns values of the Mexican hat wavelet on an N point regular grid, X, in the interval [LB,UB].

Output arguments are the wavelet function PSI computed on the grid X.

This wavelet has [-5 5] as effective support. Although [-5 5] is the correct theoretical effective support, a wider effective support, [-8 8], is used in the computation to provide more accurate results.

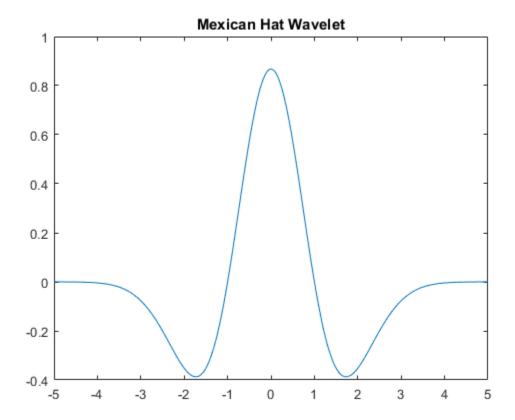

This function is proportional to the second derivative function of the Gaussian probability density function.

Examples

Mexican Hat Wavelet

Create a Mexican hat wavelet with support on [-5,5]. Use 1,000 sample points. Plot the result.

```
lb = -5;
ub = 5;
N = 1000;
[psi,xval] = mexihat(lb,ub,N);
plot(xval,psi)
title('Mexican Hat Wavelet');
```

See Also waveinfo

Introduced before R2006a

meyer

Meyer wavelet

Syntax

```
[PHI,PSI,T] = meyer(LB,UB,N)
```

Description

[PHI,PSI,T] = meyer(LB,UB,N) returns Meyer scaling and wavelet functions evaluated on an N point regular grid in the interval [LB,UB].

N must be a power of two.

Output arguments are the scaling function PHI and the wavelet function PSI computed on the grid *T*. These functions have [-8 8] as effective support.

If only one function is required, a fourth argument is allowed:

```
[PHI,T] = meyer(LB,UB,N,'phi')
[PSI,T] = meyer(LB,UB,N,'psi')
```

When the fourth argument is used, but not equal to 'phi' or 'psi', outputs are the same as in the main option.

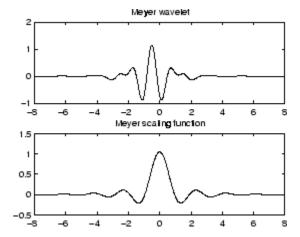

The Meyer wavelet and scaling function are defined in the frequency domain.

By changing the auxiliary function (see meyeraux for more information), you get a family of different wavelets.

Examples

```
% Set effective support and grid parameters.
lb = -8; ub = 8; n = 1024;
% Compute and plot Meyer wavelet and scaling functions.
[phi,psi,x] = meyer(lb,ub,n);
```

```
subplot(211), plot(x,psi)
title('Meyer wavelet')
subplot(212), plot(x,phi)
title('Meyer scaling function')
```

More About

Algorithms

Starting from an explicit form of the Fourier transform $\hat{\phi}$ of φ , meyer computes the values of $\hat{\phi}$ on a regular grid, and then the values of φ are computed using instdfft, the inverse nonstandard discrete FFT.

The procedure for ψ is along the same lines.

meyeraux | wavefun | waveinfo

Introduced before R2006a

meyeraux

Meyer wavelet auxiliary function

Syntax

Y = meyeraux(X)

Description

Y = meyeraux(X) returns values of the auxiliary function used for Meyer wavelet generation evaluated at the elements of the vector or matrix X.

The function is

$$35x^4 - 84x^5 + 70x^6 - 20x^7$$

Introduced before R2006a

modwt

Maximal overlap discrete wavelet transform

Syntax

```
w = modwt(x)
w = modwt(x,wname)
w = modwt(x,Lo,Hi)
w = modwt(____,lev)
w = modwt(____,'reflection')
```

Description

w = modwt(x) returns the maximal overlap discrete wavelet transform (MODWT) of the 1-D real-valued signal, x.

w = modwt(x, wname) uses the orthogonal wavelet, wname, for the MODWT.

w = modwt(x,Lo,Hi) uses the scaling filter, Lo, and wavelet filter, Hi, to compute the MODWT. These filters must satisfy the conditions for an orthogonal wavelet. You cannot specify Lo and Hi if you specify wname.

w = modwt(____,lev) computes the MODWT down to the specified level, lev, using any of the arguments from previous syntaxes.

 $w = modwt(___, reflection')$ computes the MODWT using reflection boundary handling. Other inputs can be any of the arguments from previous syntaxes. Before computing the wavelet transform, modwt extends the signal symmetrically at the right boundary to twice the signal length, [x flip(x)]. The number of wavelet and scaling coefficients that modwt returns is equal to twice the length of the input signal. By default, the signal is extended periodically.

Examples

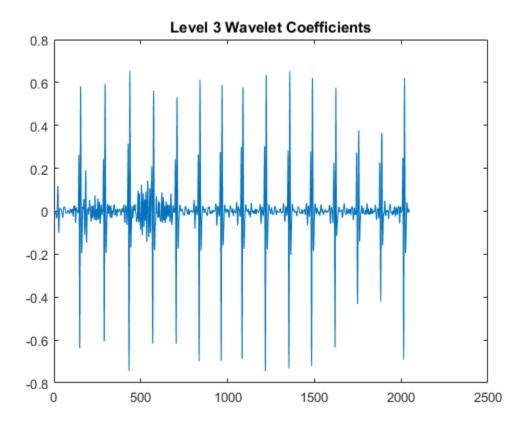

MODWT Using Default Wavelet

Obtain the MODWT of an electrocardiogram (ECG) signal using the default sym4 wavelet down to the maximum level.

```
load wecg;
wtecg = modwt(wecg);
```

wtecg is 12-by-2048 matrix. The first eleven rows are the wavelet coefficients for scales 2^1 to 2^{11} . The final row contains the scaling coefficients at scale 2^{11} . Plot the detail (wavelet) coefficients for scale 2^3 .

```
plot(wtecg(3,:))
title('Level 3 Wavelet Coefficients')
```

MODWT Using Daubechies Extremal Phase Wavelet with Two Vanishing Moments

Obtain the MODWT of Southern Oscillation Index data with the 'db2' wavelet down to the maximum level.

```
load soi;
wsoi = modwt(soi, 'db2');
```

MODWT Using Scaling and Wavelet Filters

Obtain the MODWT of the Deutsche Mark - U.S. Dollar exchange rate data using the Fejer-Korovkin length 8 scaling and wavelet filters.

```
load DM USD;
```

```
[Lo,Hi] = wfilters('fk8');
wdm = modwt(DM USD,Lo,Hi);
```

MODWT to a Specified Level

Obtain the MODWT of an ECG signal down to scale 2^4 , which corresponds to level four. Use the default 'sym4' wavelet.

```
load wecg;
wtecg = modwt(wecg,4);
```

wtecg is a 5-by-2048 matrix. The row size is L+1, where, in this case, the level (L) is 4. The column size matched the number of input samples.

MODWT with Reflection Boundary

Obtain the MODWT of an ECG signal using reflection boundary handling. Use the default 'sym4' wavelet and obtain the transform down to level 4.

```
load wecg;
wtecg = modwt(wecg,4,'reflection');
```

wtecg has 4096 columns, which is twice the length of the input signal, wecg.

"Wavelet Analysis of Financial Data"

Input Arguments

x — Input signal

real-valued vector

Input signal, specified as a row or column vector. X must have at least two elements.

By default, modwt computes the wavelet transform down to level floor(log2(length(x))) using the Daubechies least-asymmetric wavelet with four vanishing moments ('Sym4') and periodic boundary handling.

Data Types: double

wname - Analyzing wavelet

```
'sym4' (default) | string
```

Analyzing wavelet, specified as a string that corresponds to an orthogonal wavelet. Valid orthogonal wavelet families begin with one of the following strings, followed by an integer, *N*, which indicates the number of vanishing moments, for example, symN. For 'fk', *N* is the number of coefficients.

- · 'haar' Haar wavelet
- 'db' Daubechies wavelet
- · 'sym' Symlets wavelet
- · 'coif' Coiflets wavelet
- 'fk' Fejer-Korovkin wavelet

•

To check if your wavelet is orthogonal, use wavemngr('type', wname) and verify that it returns 1 as the wavelet type. To determine valid values for N, use waveinfo, for example, waveinfo('db').

Lo — Scaling filter

even-length real-valued vector

Scaling filter, specified as an even-length real-valued vector. Lo must satisfy the conditions necessary to generate an orthogonal scaling function. You can specify Lo only if you do not specify wname.

Hi — Wavelet filter

even-length real-valued vector

Wavelet filter, specified as an even-length real-valued vector. Hi must satisfy the conditions necessary to generate an orthogonal wavelet. You can specify Hi only if you do not specify wname.

1ev — Transform level

positive integer

Transform level, specified as a positive integer less than or equal to floor(log2(length(x))).

Output Arguments

w — Wavelet transform

matrix

Wavelet transform, returned as an L+1-by-N matrix containing wavelet coefficients and final-level scaling coefficients. L is the level of the MODWT. N is equal to the input signal length unless you specify 'reflection' boundary handling, in which case N is twice the length of the input signal. The kth row of w contains the wavelet coefficients for scale 2^k (wavelet scale $2^{(k-1)}$). The final, (L+1)th, row of w contains the scaling coefficients for scale 2^L .

More About

Algorithms

The standard algorithm for the MODWT implements the circular convolution directly in the time domain. This implementation of the MODWT performs the circular convolution in the Fourier domain. The wavelet and scaling filter coefficients at level j are computed by taking the inverse discrete Fourier transform (DFT) of a product of DFTs. The DFTs in the product are the signal's DFT and the DFT of the jth level wavelet or scaling filter.

Let H_k and G_k denote the length N DFTs of the MODWT wavelet and scaling filters, respectively. Let j denote the level and N denote the sample size.

The j^{th} level wavelet filter is defined by

$$rac{1}{N}\sum_{k=0}^{N-1}H_{j,k}e^{i2\pi nk/N}$$

where

$$H_{j,k} = H_{2^{j-1}k \mod N} \prod_{m=0}^{j-2} G_{2^m k \mod N}$$

The jth level scaling filter is

$$rac{1}{N}\sum_{k=0}^{N-1}G_{j,k}e^{i2\pi nk/N}$$

where

$$G_{j,k} = \prod_{m=0}^{j-1} G_{2^m k \bmod N}$$

Introduced in R2015b

modwtcorr

Multiscale correlation using the maximal overlap discrete wavelet transform

Syntax

```
wcorr = modwtcorr(w1,w2)
wcorr = modwtcorr(w1,w2,wav)

[wcorr,wcorrci] = modwtcorr(____,conflevel)
[wcorr,wcorrci,pval] = modwtcorr(____)
[wcorr,wcorrci,pval,nj] = modwtcorr(___)
wcorrtable = modwtcorr(___,'table')

[___] = modwt(___,'reflection')
modwtcorr(___)
```

Description

wcorr = modwtcorr(w1,w2) returns the wavelet correlation by scale for the maximal overlap discrete wavelet transforms (MODWTs) specified in w1 and w2. wcorr is an M-by-1 vector of correlation coefficients, where M is the number of levels with nonboundary wavelet coefficients. If the final level has enough nonboundary coefficients, modwtcorr returns the scaling correlation in the final row of wcorr.

wcorr = modwtcorr(w1, w2, wav) uses the wavelet wav to determine the number of boundary coefficients by level.

[wcorr,wcorrci] = modwtcorr(____) returns in wcorrci the lower and upper 95% confidence bounds for the correlation coefficients of wcorr, using any arguments from the previous syntaxes.

[wcorr,wcorrci] = modwtcorr(____,conflevel) uses conflevel for the coverage probability of the confidence interval. conflevel is a real scalar strictly greater than 0 and less than 1. If conflevel is unspecified or specified as empty, the coverage probability defaults to 0.95.

Examples

Correlation by Scale

Find the correlation by scale for monthly DM-USD exhange rate returns from 1970 to 1998. The return data are log transformed. Use the Daubechies wavelet with two

vanishing moments ('db2') to obtain the MODWT down to level 6. Then, obtain the correlation data.

```
load DM_USD;
load JY_USD;
wdm = modwt(DM_USD, 'db2',6);
wjy = modwt(JY_USD, 'db2',6);
wcorr = modwtcorr(wdm,wjy, 'db2')

wcorr =

    0.5854
    0.5748
    0.6264
    0.4948
    0.3787
    0.9072
    0.7976
```

wcorr contains seven elements. The first six elements are the correlation coefficients for the wavelet (detail) levels one to six. The final element is the correlation for the scaling (lowpass) level six.

Multiscale Correlation

Obtain the MODWT of the Southern Oscillation Index and Truk Island daily pressure data sets. Tabulate the correlation between the two data sets by level.

```
load soi;
load truk;
wsoi = modwt(soi);
wtruk = modwt(truk);
wcorr = modwtcorr(wsoi,wtruk)

wcorr =
    0.1749
    0.2936
    0.0914
    0.0883
    0.2667
```

```
0.0894
-0.0415
0.4825
0.4394
0.7433
```

Show that the number of nonboundary coefficients, in this case, is less than the maximal length of the input. The MODWT is computed down to level thirteen, which is the maximal level for the length of the input. Level thirteen contains thirteen wavelet coefficient vectors and one scaling coefficient vector.

```
size(wsoi,1)
ans =
    14
```

The multiscale correlations are computed only down to level ten because the levels after than do not contain nonboundary coefficients. For unbiased estimates, you must use nonboundary coefficients only.

```
numel(wcorr)
ans =
    10
```

Confidence Intervals for Correlation

Obtain the MODWT of the monthly US-DM and US-JPY exchange return data from 1970 to 1998. The return data are log transformed. Use the Daubechies wavelet with two degrees of freedom ('db2') and obtain wavelet and obtain the MODWT of each series down to level six. Obtain the correlation estimates by scale and the 95% confidence intervals.

```
load DM_USD
load JY_USD
wdm = modwt(DM_USD, 'db2',6);
wjy = modwt(JY_USD, 'db2',6);
[wcorr,wcorrci] = modwtcorr(wdm,wjy, 'db6');
```

[wcorr wcorrci] ans = 0.5855 0.4780 0.6756 0.5753 0.4139 0.7017 0.4007 0.6257 0.7796 0.5578 0.1661 0.7974 0.7202 0.1657 0.9287

The width of the confidence interval increases as you go down in level.

Confidence Intervals with 0.99 Coverage Probability

Specify the coverage probability for the confidence intervals. Obtain the 99% confidence intervals for the US-DM and US-JY exchange returns.

```
load DM USD;
load JY USD;
wdm = modwt(DM USD, 'db2', 6);
wjy = modwt(JY USD, 'db2', 6);
[wcorr,wcorrci] = modwtcorr(wdm,wjy,'db2',0.99);
[wcorr wcorrci]
ans =
    0.5854
              0.4407
                         0.7005
    0.5748
              0.3557
                         0.7340
    0.6264
              0.3169
                         0.8153
    0.4948
             -0.0646
                         0.8176
    0.3787
             -0.5191
                         0.8792
    0.9072
             -0.3006
                         0.9975
    0.7976
             -0.6227
                         0.9941
```

P-values for Correlation

Return p-values for the test of zero correlation by scale. Obtain the MODWT of the DM-USD and JY-USD exchange return data down to level six using the Daubechies wavelet with two degrees of freedom ('db2') wavelet. Compute the correlation by scale and return the p-values.

```
load DM USD;
load JY USD;
wdm = modwt(DM USD, 'db2',6);
wjy = modwt(JY USD, 'db2', 6);
[wcorr,wcorrci,pval] = modwtcorr(wdm,wjy,'db2');
format longe
pval
format
pval =
     2.694174887029476e-17

                                3.204132967562528e-01
```

The first column contains the p-value and the second column contains the adjusted p-value based on the false discovery rate.

Multiscale Correlation in Tabular Form

Output results from modwtcorr in tabular form. Obtain the MODWT of the DM-USD and JY-USD exchange returns down to level six using the Daubechies wavelet with two degrees of freedom ('db2'). Output the results in a table.

```
load DM USD;
load JY USD;
wdm = modwt(DM USD, 'db2',6);
wjy = modwt(JY USD, 'db2', 6);
corrtable = modwtcorr(wdm,wjy,'db2','table')
corrtable =

Correlation with Reflection Boundary Conditions

Obtain multiscale correlation estimates when using 'reflection' boundary handling. Obtain the MODWT of the Southern Oscillation Index and Truk Islands pressure data sets using 'reflection' boundary handling for both data sets.

```
load soi
load truk
wsoi = modwt(soi,'fk4',6,'reflection');
wtruk = modwt(truk,'fk4',6,'reflection');
corrtable = modwtcorr(wsoi,wtruk,'fk4',0.95,'reflection','table')
```

Plot Correlation with Confidence Intervals

Plot the multiscale correlation of the DM-USD and JY-USD exchange returns down to level six. Use modwtcorr with no output arguments.

```
load DM_USD;
load JY_USD;
wdm = modwt(DM_USD,'db2',6);
wjy = modwt(JY_USD,'db2',6);
modwtcorr(wdm,wjy,'db2')
```

- · "Wavelet Cross-Correlation for Lead-Lag Analysis"
- · "Wavelet Analysis of Financial Data"

Input Arguments

w1 — MODWT transform of signal 1

matrix

MODWT transform of signal 1, specified as a matrix. W1 is the output of modwt. It must be the same size and must have been obtained using the same analyzing wavelet.

Data Types: double

w2 — MODWT transform of signal 2

matrix

MODWT transform of signal 2, specified as a matrix. w2 is the output of modwt. It must be the same size and must have been obtained using the same analyzing wavelet.

wav - Wavelet

'sym4' (default) | string | positive even scalar

Wavelet, specified as a string indicating a valid wavelet string or as a positive even scalar indicating the length of the wavelet and scaling filters. wav must be the same wavelet and length used to obtain the MODWTs of w1 and w2. For a list of valid wavelets, see modwt. If unspecified or specified as an empty, [], wav defaults to the symlets wavelet with four degrees of freedom, 'sym4'.

conflevel - Confidence level

0.95 (default) | positive scalar less than 1

Confidence level, specified as a positive scalar less than 1. conflevel determines the coverage probability of the confidence intervals in wcorrci and in the table, if you specify 'table' as an input. If unspecified, or if specified as empty, [], conflevel defaults to 0.95.

Output Arguments

wcorr — Correlation coefficients by scale

vector

Correlation coefficients by scale, returned as a vector. WCOrr is an M-by-1 vector of correlation coefficients, where M is the number of levels with nonboundary wavelet coefficients. Modwtcorr returns correlation estimates only where there are nonboundary coefficients. This condition is satisfied when the transform level is not greater than floor(log2(N/(L-1)+1)), where N is the length of the original signal and L is the filter length. If the final level has enough nonboundary coefficients, modwtcorr returns the scaling correlation in the final row of wcorr. By default, modwtcorr uses the symlet wavelet with four degrees of freedom 'sym4' to determine the boundary coefficients.

wcorrci — Confidence intervals by scale

matrix

Confidence intervals by scale, returned as a matrix. The matrix is of size M-by-2, where M is the number of levels with nonboundary wavelet coefficients. The first column contains the lower confidence bound and the second column contains the upper confidence bound. The conflevel determines the coverage probability.

Confidence bounds are computed using Fisher's Z-transformation. The standard error of Fisher's Z statistic is the square root of (N-3). In this case, N is the equivalent number of coefficients in the critically sampled discrete wavelet transform (DWT), floor(size(w1,2)/2^LEV), where LEV is the level of the wavelet transform. modwtcorr returns NaNs for the confidence bounds when N^3 is less than or equal to zero.

pva1 — P-values for null hypothesis test

matrix

P-values for null hypothesis test, returned as a matrix. pval is an M-by-2 matrix.

- The first column of pval is the *p*-value computed using the standard *t*-statistic test for a correlation coefficient of zero.
- The second column of pval contains the adjusted *p*-value using the false discovery procedure of Benjamini & Yekutieli under arbitrary dependence assumptions.

The degrees of freedom, (N-2), for the t-statistic are determined by the equivalent number of coefficients in the critically sampled DWT, floor(size(w1,2)/2^LEV), where LEV is the levels of the wavelet transform. modwtcorr returns NaNs when N^3 is less than or equal to zero.

nj — Number of nonboundary coefficients

vector

Number of nonboundary coefficients by scale, returned as a vector.

wcorrtable - Correlation table

table

Correlation table, returned as a MATLAB table. The table contains six variables:

NJ — Number of nonboundary coefficients by level.

- Lower Lower confidence bound for the coverage probability specified by conflevel.
- **Rho** Correlation coefficient.
- Upper Upper confidence bound for the coverage probability specified by conflevel.
- **Pvalue** P-value for hypothesis test. The null hypothesis is that the correlation coefficient is equal to zero.
- **Adjusted Pvalue** P-value adjusted for multiple comparisons. The p-values are adjusted using false discovery rate under dependency assumptions.

imodwt | modwt | modwtmra | modwtvar | modwtxcorr

Introduced in R2015b

modwtmra

Multiresolution analysis based on MODWT

Syntax

```
mra = modwtmra(w)
mra = modwtmra(w,wname)
mra = modwtmra(w,Lo,Hi)
mra = modwtmra(____,'reflection')
```

Description

mra = modwtmra(w) returns the multiresolution analysis (MRA) of the maximal overlap discrete wavelet transform (MODWT) matrix, w. The MODWT matrix, w, is the output of the modwt function.

mra = modwtmra(w,wname) constructs the MRA using the wavelet corresponding to wname. The wname wavelet must be the same wavelet used to obtain the MODWT.

mra = modwtmra(w,Lo,Hi) constructs the MRA using the scaling filter Lo and wavelet filter Hi. The Lo and Hi filters must be the same filters used to obtain the MODWT.

mra = modwtmra(____, 'reflection') uses the reflection boundary condition in the construction of the MRA using any of the arguments from previous syntaxes. If you specify 'reflection', modwtmra assumes that the length of the original signal is one half the number of columns in the input coefficient matrix.

Examples

Perfect Reconstruction with the MODWTMRA

Obtain the MODWTMRA of a simple time-series signal and demonstrate perfect reconstruction.

Create a time-series signal

```
t = 1:10;
x =sin(2*pi*200*t);
```

Obtain the MODWT and the MODWTMRA and sum the MODWTMRA rows.

```
m = modwt(x);
mra = modwtmra(m);
xrec = sum(mra);
```

Use the maximum of the absolute values to show that the difference between the original signal and the reconstruction is extremely small. The largest absolute value is on the order of 10^{-25} , which demonstrates perfect reconstruction.

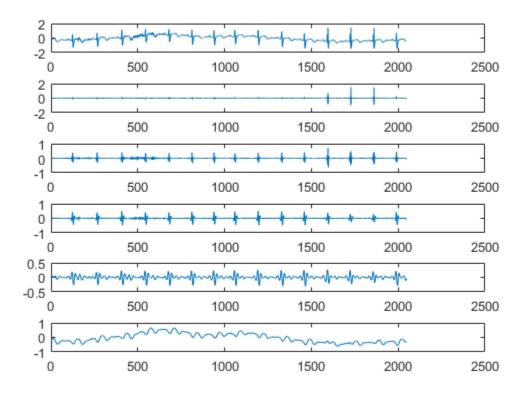

```
max(abs(x-xrec))
ans =
5.5738e-25
```

MRA Using Non-Default Wavelet

Construct an MRA of an ECG signal down to level four using the 'db2' wavelet.

```
load wecg;
lev = 4;
wtecg = modwt(wecg, 'db2',lev);
mra = modwtmra(wtecg, 'db2');

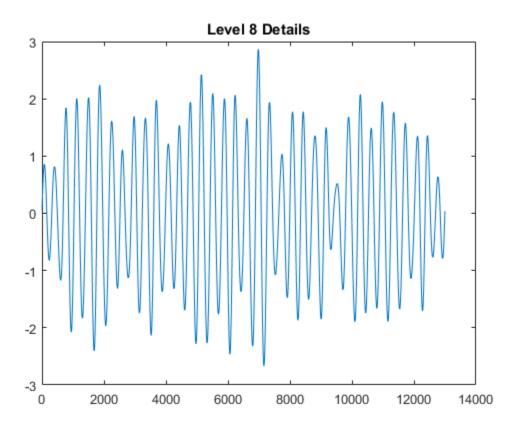

Plot the ECG waveform and the MRA.
subplot(6,1,1)
plot(wecg)
    for kk = 2:lev+2
        subplot(6,1,kk)
        plot(mra(kk-1,:))
end
```

MRA Using the Default Wavelet

Construct a multiresolution analysis for the Southern Oscillation Index data. The sampling period is one day. Plot the level eight details corresponding to a scale of 2^8 days. The details at this scale capture oscillations on a scale of approximately one year.

```
load soi
wtsoi = modwt(soi);
mrasoi = modwtmra(wtsoi);
plot(mrasoi(8,:))
title('Level 8 Details')
```

MRA Using Minimum Bandwidth Scaling and Wavelet Filters

Obtain the MRA for the Deutsch Mark - U.S. Dollar exchange rate data using the minimum bandwidth scaling and wavelet filters with four coefficients.

```
load DM_USD;
Lo = [0.4801755, 0.8372545, 0.2269312, -0.1301477];
Hi = qmf(Lo);
wdm = modwt(DM_USD,Lo,Hi);
mra = modwtmra(wdm,Lo,Hi);
```

MRA Using Reflection Boundary

Obtain the MRA for an ECG signal using 'reflection' boundary handling.

```
load wecg;
wtecg = modwt(wecg, 'reflection');
mra = modwtmra(wtecg, 'reflection');
```

Show that the number of columns in the MRA is equal to the number of elements in the original signal.

```
isequal(size(mra,2),numel(wecg))
ans =
```

Input Arguments

w - MODWT transform

matrix

Maximal overlap discrete wavelet transform, specified as a matrix. W is the output of modwt.

The input w is an L+1-by-N matrix containing the MODWT of an N-point input signal down to level L. By default, modwtmra assumes that you obtained the MODWT using the symlet wavelet with four vanishing moments, 'sym4', and using periodic boundary handling.

Example:

Data Types: double

wname - Synthesis wavelet

```
'sym4' (default) | string
```

Synthesis wavelet, specified as a string. The synthesis wavelet must be the same wavelet used to obtain the MODWT with the modwt function.

Lo — Scaling filter

even-length real-valued vector

Scaling filter, specified as an even-length real-valued vector. You can specify LO only if you do not specify wname. LO must be the same scaling filter used to obtain the MODWT with the modwt function.

Hi — Wavelet filter

even-length real-valued vector

Wavelet filter, specified as an even-length real-valued vector. You can specify Hi only if you do not specify wname. Hi must be the same wavelet filter used to obtain the MODWT with the modwt function.

Output Arguments

mra — Multiresolution analysis

matrix

Multiresolution analysis, returned as a matrix. By default, the mra is the same size as the input transform matrix w. If you specify reflection boundary handling, then mra has one half the number of columns as the input matrix w.

The output mra is an L+1-by-N matrix. The $k^{\rm th}$ row of mra contains the details for the $k^{\rm th}$ level. The $(L+1)^{\rm th}$ row of mra contains the $L^{\rm th}$ level smooth.

```

Description

wvar = modwtvar(w) returns unbiased estimates of the wavelet variance by scale for the maximal overlap discrete wavelet transform (MODWT). The default wavelet type is sym4.

wvar = modwtvar(w, wname) uses the wavelet wname to determine the number of boundary coefficients by level for unbiased estimates.

[wvar,wvarc1] = modwtvar() returns the 95% confidence intervals for the variance estimates by scale.
[] = modwtvar(w,wname,,conflevel) uses conflevel for the coverage probability of the confidence interval.
[] = modwtvar(w,wname,,Name,Value,) returns wavelet variance with additional options specified by one or more Name,Value pair arguments.

[wvar,wvarci,nj] = modwtvar(w,wname, ____) returns the number of coefficients used to form the variance and confidence intervals by level.

wvartable = modwtvar(w,wname, 'table'), where 'table' returns a MATLAB table, wvartable, containing the number of MODWT coefficients by level, the confidence boundaries, and the variance estimates. You can place 'table' anywhere after input w, except between the name and value of another Name, Value pair.

modwtvar(_____) with no output arguments plots the wavelet variances by scale with lower and upper confidence bounds. The scaling variance is not included in the plot because the scaling variance can be much larger than the wavelet variances.

Examples

Wavelet Variance Using Default Wavelet

Obtain the MODWT of the Southern Oscillation Index data using the default symlets wavelet with 4 vanishing moements. Compute the unbiased estimates of the wavelet variance by scale.

```
load soi
wsoi = modwt(soi);
wvar = modwtvar(wsoi)

wvar =

    0.3568
    0.9026
    1.1576
    1.0952
    0.9678
    0.5478
    0.6353
    1.9570
    0.8398
    0.8247
```

Wavelet Variance Using Specified Wavelet

Obtain the MODWT of the Southern Oscillation Index data using the Daubechies wavelet with 2 vanishing moments ('db2'). Compute the unbiased estimates of the wavelet variance by scale.

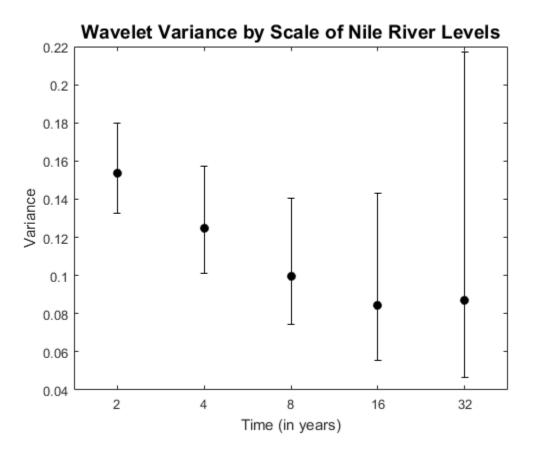

```
load soi
wsoi = modwt(soi, 'db2');
wvar = modwtvar(wsoi, 'db2')
wvar =
    0.4296
    0.9204
    1.1370
    1.0847
    0.9255
    0.5932
    0.7630
    1.6672
    0.8048
    0.7555
    0.2095
    0.0377
```

Variance Estimates and Confidence Intervals Using MODWTVAR

Obtain the MODWT of the Nile River minimum level data using the Fejer-Korovkin wavelet with eight coefficients down to level five. Use modwtvar to obtain and plot the variance estimates and 95% confidence intervals.

```
load nileriverminima;
wtnile = modwt(nileriverminima,'fk8',5);
[wnilevar,wvarci] = modwtvar(wtnile,'fk8');

errlower = (wnilevar-wvarci(:,1));
errupper = (wvarci(:,2)-wnilevar);
errorbar(1:5,wnilevar(1:5),errlower(1:5),...
        errupper(1:5),'ko','markerfacecolor','k')
hold on
title('Wavelet Variance by Scale of Nile River Levels','fontsize',14);
ylabel('Variance');
xlabel('Time (in years)');
ax = gca;
ax.XTick = [1:5];
ax.XTickLabel = {'2','4','8','16','32'};
hold off
```

Wavelet Confidence Intervals

Show how different confidence level values affect the width of the confidence intervals. An increased confidence level value increases the confidence interval width.

Obtain the MODWT of the Southern Oscillation Index data using the Fejer-Korovkin wavelet with eight coefficients.

```
load soi;
wsoi = modwt(soi, 'fk8');
```

Obtain the width of the .90, .95, and .99 confidence intervals for each level.

```
[~,wvarci90] = modwtvar(wsoi, 'fk8',0.90);
```

```
w90 = wvarci90(:,2)-wvarci90(:,1);
[~,wvarci95] = modwtvar(wsoi,'fk8',0.95);
w95 = wvarci95(:,2)-wvarci95(:,1);
[~,wvarci99] = modwtvar(wsoi,'fk8',0.99);
w99 = wvarci99(:,2)-wvarci99(:,1);
```

Compare the three columns. The first column shows the .90 confidence level values, the second the .95 values, and the third the .99 values. Each row is the width of the interval at each wavelet scale. You can see that the width of the confidence interval increases with larger confidence level values.

```

Compare Chi2Eta2 and Gaussian Confidence Intervals

Specify non-default confidence methods using name-value pairs to compare the width of their confidence levels. Note that for Gaussian confidence level intervals, it is possible to obtain negative lower confidence bounds.

Obtain the MODWT of the Southern Oscillation Index data using the Fejer-Korovkin wavelet with eight coefficients.

```
load soi;
wsoi = modwt(soi,'fk8');
```

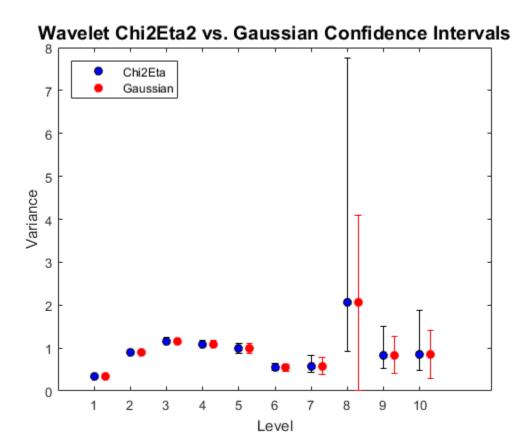

Use the Chi2Eta and Gaussian confidence methods to obtain the variances and confidence interval bounds for each method.

```
[wvar c,wvarci c] = modwtvar(wsoi, 'fk8',[], 'ConfidenceMethod', 'chi2eta1');
```

```
[wvar_g,wvarci_g] = modwtvar(wsoi, 'fk8',[], 'ConfidenceMethod', 'gaussian');
```

Compute the upper and lower errors for each confidence interval and plot the results. Note that the Gaussian intervals are slightly shifted to enable better visualization.

```
errlower c = wvar c-wvarci c(:,1);
errupper c = wvarci c(:,2)-wvar c;
errlower g = wvar g(:,1) - wvarci g(:,1);
errupper_g = wvarci_g(:,2)-wvar_g;
errorbar(1:10, wvar c(1:10), errlower c(1:10),...
    errupper_c(1:10), 'ko', 'markerfacecolor', 'b')
hold on;
xoffset = (1.3:10.3);
errorbar(xoffset, wvar g(1:10), errlower g(1:10),...
    errupper g(1:10), 'ro', 'markerfacecolor', 'r')
title('Wavelet Chi2Eta2 vs. Gaussian Confidence Intervals', 'fontsize', 14);
ylabel('Variance');
xlabel('Level')
ax = gca;
ax.XTick = [1:10];
legend('Chi2Eta','Gaussian','Location','northwest');
hold off
```

Compare Number of Coefficients for Unbiased and Biased Variance Estimates

Compare the number of coefficients for unbiased and biased wavelet variance estimates. For the unbiased (default) estimates, the number of nonboundary coefficients decreases by scale. For biased estimates, the number of coefficients matches the number of input rows and is constant for every scale.

Obtain the MODWT of the Southern Oscillation Index data using the Fejer-Korovkin wavelet with eight coefficients. Compute the unbiased and biased estimates of the wavelet variance down to level ten. The number of coefficients used in the unbiased estimates decrease by scale.

load soi

```
wsoi = modwt(soi, 'fk8');

The resulting table contains the number of nonboundary coefficients, the lower and upper conficence level bounds, and the variance estimate for each level.

· "Wavelet Analysis of Financial Data"

Input Arguments

w - MODWT transform matrix

matrix

MODWT transform, specified as a matrix. W is the output of modwt.

Data Types: double

wname - Wavelet

'sym4' (default) | string | positive even scalar

Wavelet, specified as a string corresponding to a valid wavelet, or as a positive even scalar indicating the length of the wavelet and scaling filters. The wavelet filter length must match the length used in the MODWT of the input.

If you use Name, Value pairs arguments or the 'table' syntax and you did not specify a wname, you must use [] as the second argument.

conflevel — Confidence level

0.95 (default) | real scalar greater than 0 and less than 1

Confidence level, specified as a real scalar value greater than 0 and less than 1. The confidence level determines the coverage probability of the confidence intervals. The confidence levels are also shown in wvartable, if you specify 'table' as an input.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'EstimatorType', 'biased' specifies a biased estimator.

'EstimatorType' — Estimator 'unbiased' (default) | 'biased'

Type of estimator used for variance estimates and confidence bounds, specified as the comma-separated pair consisting of 'EstimatorType' and one of these values.

- 'unbiased' Unbiased estimator, which identifies and removes boundary coefficients
 prior to computing the variance estimates and confidence bounds. Unbiased estimates
 are used more frequently for wavelet variance computations.
- 'biased' Biased estimator, which uses all coefficients to compute the variance estimates and confidence bounds.

'ConfidenceMethod' — Confidence method

```
'chi2eta3' (default) | 'chi2eta1' | 'gaussian'
```

Confidence method used to compute the confidence intervals, specified as the commaseparated pair consisting of 'ConfidenceMethod' and one of these values:

'chi2eta3'	Chi-square probabil	lity density method three	, which

determines the degrees of freedom.[1].

'chi2eta1' Chi-square probability density method one, which

determines the degrees of freedom [1].

'gaussian' Gaussian method [1]. This method can result in negative

lower bounds.

See "Algorithm" on page 1-347 for information on each of these confidence methods.

'Boundary' — Boundary condition

```
'periodic' (default) | 'reflection'
```

Boundary condition used to compute the variance estimates and confidence bounds, specified as the comma-separated pair consisting of 'Boundary' and one of these values:

'periodic'

Periodic boundary handling, which does not change the original signal before computing the MODWT. If modwt uses periodic boundary handling, you must specify 'Boundary', 'periodic' for modwtvar to obtain a correct estimate. 'reflection'

Reflection boundary handling. If the MODWT uses reflection boundary handling, you must also specify 'Boundary', 'reflection' for modwtvar to obtain a correct unbiased estimate. The MODWT, with reflection boundary handling, extends the original signal symmetrically at the right boundary to twice the signal length. The MODWTVAR algorithm has to know about this extended signal to calculate the correct unbiased estimate.

For biased estimators, all the coefficients are used to form the variance estimates and confidence intervals regardless of the boundary handling.

Output Arguments

wvar - Wavelet variance estimates

matrix

Wavelet variance estimates, returned as vector. The number of elements in wvar depends on the number of scales in the input matrix and, for unbiased estimates, on the wavelet length. For the unbiased case, modwtvar returns estimates only where nonboundary coefficients exist. This condition is satisfied when the transform level is not greater than floor(log2(N/(L-1)+1)), where N is the input signal length and L is the length of the wavelet filter. The number of biased estimates equals the input signal length. If the final level has sufficient nonboundary coefficients, modwtvar returns the scaling variance in the final element of wvar.

wvarci - Confidence intervals for each variance estimate

matrix

Confidence bounds, expressed as upper and lower confidence bounds, for the variance estimates in wvar, returned as a matrix. The default is 95% confidence bounds, but you can use a different value using the conflevel input argument. The confidence bounds matrix is *M*-by-2, where *M* is the number of levels. For unbiased estimates, the number of levels is limited by the number of nonboundary coefficients. For biased

estimates, all levels are used. The first column of the confidence interval matrix contains the lower confidence bound and the second column contains the upper confidence bound. By default, modwtvar calculates the confidence intervals using the chi-square probability density, with the equivalent degrees of freedom estimated using the 'Chi2Eta3' confidence method.

nj - Number of coefficients by level

vector

Number of nonboundary coefficients by scale, returned as a vector. For unbiased estimates, nj is the number of nonboundary coefficients and decreases by level. For biased estimates, nj is a vector of constants equal to the number of columns in the input matrix.

wvartable - Variance table

table

Variance table, returned as a MATLAB table. The four variables in the table are:

- NJ Number of MODWT coefficients by level. For biased estimates, NJ is the number of coefficients in the MODWT. For unbiased estimates, NJ is the number of nonboundary coefficients.
- Lower Lower confidence bound for the variance estimate.
- · Variance Variance estimate by level.
- **Upper** Upper confidence bound for the variance estimate.

The row names of wvartable indicate the type and level of each estimate. For example, D1 indicates that the row corresponds to a wavelet or detail estimate at level 1. S6 indicates that the row corresponds to the scaling estimate at level 6. The scaling variance is computed for the final level of the MODWT. For unbiased estimates, modwtvar computes the scaling variance only when nonboundary scaling coefficients exist.

More About

Algorithms

The following expressions define the variance and confidence methods used in the MODWTVAR. The variables are

• N_j — Number of coefficients at level j

- v^2 Variance
- j Level
- $W_{j,t}$ Wavelet coefficients

The variance estimate is

$$\hat{v}_{j}^{2} = \frac{1}{N_{j}} \sum_{t=0}^{N_{j}-1} W_{j,t}^{2}$$

The degrees of freedom for the Chi2Eta1 (chi2eta1) method are defined as

$$\eta_1 = \frac{N_j \hat{v}_j^4}{\hat{A}_j}$$

where

$$\hat{A}_{j} = \frac{1}{2} \int_{-1/2}^{1/2} \left[\hat{S}_{j}^{(p)}(f) \right]^{2} df$$

In this equation, $\hat{S}_{j}^{(p)}$ is the spectral density function estimate of the wavelet coefficients at level j.

The chi-square statistic is

$$\frac{\eta_1 N_j \hat{v}_j^2}{v_j^2} \sim \mathbf{X}_{\eta_1}^2$$

The degrees of freedom for the Chi2Eta3 (chi2eta3) method are defined as

$$\eta_3 = \max\left(\frac{N_j}{2^j}, 1\right)$$

The chi-square statistic is

$$\frac{\eta_3 N_j \hat{v}_j^2}{v_i^2} \sim X_{\eta_3}^2$$

For the Gaussian method, the statistic

$$\frac{N_{j}^{1/2} \left((v_{j}^{2} - v_{j}^{2}) \right)}{\left(2A_{j} \right)^{1/2}}$$

is distributed as N(0,1). The variable \hat{A}_j is as described for chi2eta1.

Introduced in R2015b

modwtxcorr

Wavelet cross-correlation sequence estimates using the maximal overlap discrete wavelet transform (MODWT)

Syntax

```
xcseq = modwtxcorr(w1,w2)
xcseq = modwtxcorr(w1,w2,wav)

[xcseq,xcseqci] = modwtxcorr(____)
[xcseq,xcseqci] = modwtxcorr(w1,w2,wav,conflevel)
[xcseq,xcseqci,lags] = modwtxcorr(____)

[___] = modwtxcorr(____,'reflection')
```

Description

xcseq = modwtxcorr(w1,w2) returns the wavelet cross-correlation sequence estimates for the maximal overlap discrete wavelet transform (MODWT) transforms specified in w1 and w2. xcseq is a cell array of vectors where the elements in each cell correspond to cross-correlation sequence estimates. If there are enough nonboundary coefficients at the final level, modwtxcorr returns the scaling cross-correlation sequence estimate in the final cell of xcseq.

xcseq = modwtxcorr(w1,w2,wav) uses the wavelet wav to determine the number of boundary coefficients by level.

[xcseq,xcseqci] = modwtxcorr(____) returns in xcseqci the 95% confidence intervals for the cross-correlation sequence estimates in xcseq, using any arguments from the previous syntaxes.

[xcseq,xcseqci] = modwtxcorr(w1,w2,wav,conflevel) uses conflevel for the coverage probability of the confidence interval. conflevel is a real scalar strictly greater than 0 and less than 1. If conflevel is unspecified or specified as empty, the coverage probability defaults to 0.95. [xcseq,xcseqci,lags] = modwtxcorr(____) returns the lags for the wavelet cross-correlation sequence estimates in a cell array of column vectors.

[___] = modwtxcorr(___, 'reflection') reduces the number of wavelet and scaling coefficients at each scale by half before computing the cross-correlation sequences. Specifying the 'reflection' option in modwtxcorr is equivalent to first obtaining the MODWT of w1 w2 with 'periodic' boundary handling and then computing the wavelet cross-correlation sequence estimates. Use this option only when you obtain the MODWT of w1 and w2 using the 'reflection' boundary condition. You must enter the entire string 'reflection'. If you added a wavelet named

'reflection' using the wavelet manager, you must rename that wavelet prior to using this option. 'reflection' may be placed in any position in the input argument list

Examples

Cross-Correlation Sequence

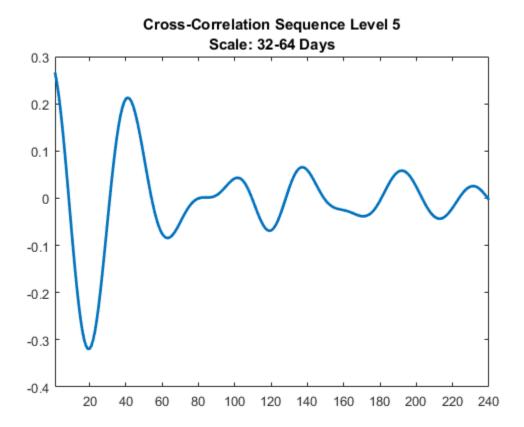

after the input transforms w1 w2.

Obtain the MODWT of the Southern Oscillation Index and Truk Islands pressure data. The sampling period is one day.

```
load soi
load truk
wsoi = modwt(soi);
wtruk = modwt(truk);
```

Compute the wavelet cross-correlation sequences. Examine the level-five cross-correlation sequence corresponding to a scale of 32-64 days. Determine the index corresponding to a lag of zero and plot out to 240 lags.

```
xcseq = modwtxcorr(wsoi,wtruk);
zerolag = floor(numel(xcseq{5})/2)+1;
plot(xcseq{5}(zerolag:zerolag+240),'linewidth',2)
set(gca,'xlim',[1 240]);
title({'Cross-Correlation Sequence Level 5'; 'Scale: 32-64 Days'});
hold off
```

Cross-Correlation Sequence with Fejer-Korovkin Wavelet

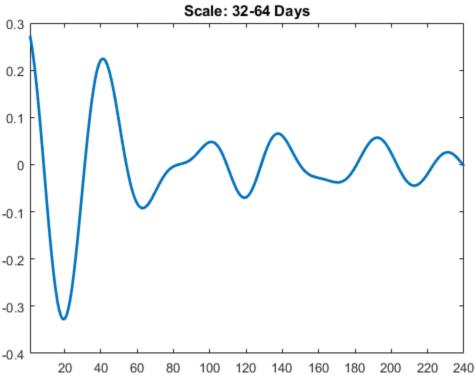

Obtain the MODWT of the Southern Oscillation Index and Truk Islands pressure data using the Fejer-Korovkin wavelet filter with 8 coefficients. The sampling period of the data is one day.

```
load soi
load truk
wsoi = modwt(soi,'fk8');
wtruk = modwt(truk,'fk8');
```

Compute the wavelet cross-correlation sequences. Examine the level-five cross-correlation sequence corresponding to a scale of 32-64 days. Determine the index corresponding to a lag of zero and plot out to 240 lags.

```
xcseq = modwtxcorr(wsoi,wtruk,'fk8');
zerolag = floor(numel(xcseq{5})/2)+1;
plot(xcseq{5}(zerolag:zerolag+240),'linewidth',2)
set(gca,'xlim',[1 240]);
title({'Cross-Correlation Sequence Level 5'; 'Scale: 32-64 Days'});
hold off
```

Cross-Correlation Sequence Level 5

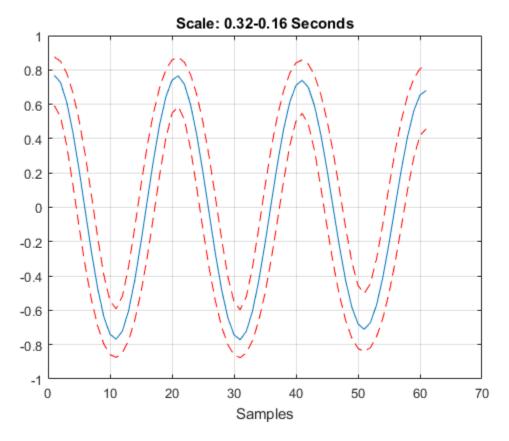

Cross-Correlation Confidence Intervals by Scale

Plot the wavelet cross-correlation with 95% confidence intervals at scale 4 for two 5-Hz sine wave signals with additive noise.

```
dt = 0.01;
t = 0:dt:6;
x = cos(2*pi*5*t)+1.5*randn(size(t));
```

```
y = cos(2*pi*5*t-pi)+2*randn(size(t));
wx = modwt(x,'fk14',5);
wy = modwt(y,'fk14',5);
modwtcorr(wx,wy,'fk14')
j = 4;
[xcseq,xcseqci] = modwtxcorr(wx,wy,'fk14');
zerolag = floor(numel(xcseq{j})/2)+1;
lagidx = zerolag-30:zerolag+30;
plot(xcseq{j}(lagidx));
hold on;
grid
plot(xcseqci{j}(lagidx,:),'r--');
xlabel('Samples');
title('Scale: 0.32-0.16 Seconds');
```

Cross-Correlation .90 and .95 Confidence Intervals Comparison

Compare the .90 and .95 (default) confidence intervals for the wavelet cross-correlation at level four.

Obtain the MODWT for two noisy sine waves using the Fejer-Korovkin with 14 coefficients, and specify the level to use.

```
dt = 0.01;
t = 0:dt:6;
x = cos(2*pi*5*t)+1.5*randn(size(t));
y = cos(2*pi*5*t-pi)+2*randn(size(t));
wx = modwt(x, 'fk14',4);
wy = modwt(y, 'fk14',4);
```

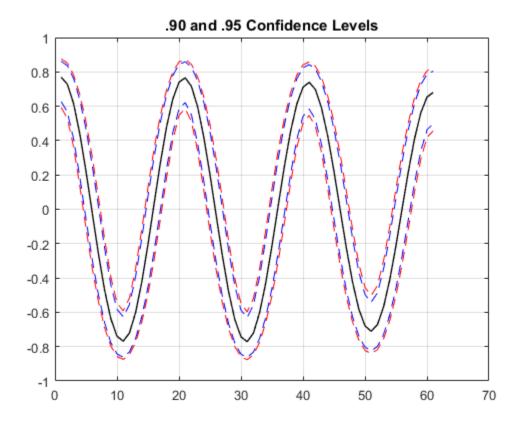

```
lev = 4;

[xcseq,xcseqci] = modwtxcorr(wx,wy,'fk14');
[xcseq90,xcseqci90] = modwtxcorr(wx,wy,'fk14',0.90);

zerolag = floor(numel(xcseq{lev})/2)+1;
zerolag90 = floor(numel(xcseq90{lev})/2)+1;

lagidx = zerolag-30:zerolag+30;
lagidx90 = zerolag90-30:zerolag90+30;

plot(xcseqci{lev}(lagidx,:),'--r');
hold on
plot(xcseqci90{lev}(lagidx90,:),'--b');
plot(xcseq{lev}(lagidx),'-k','LineWidth',1);
grid
title('.90 and .95 Confidence Levels')
```

Notice that the .95 confidence interval width (in red) is larger than the .90 confidence interval width (in blue).

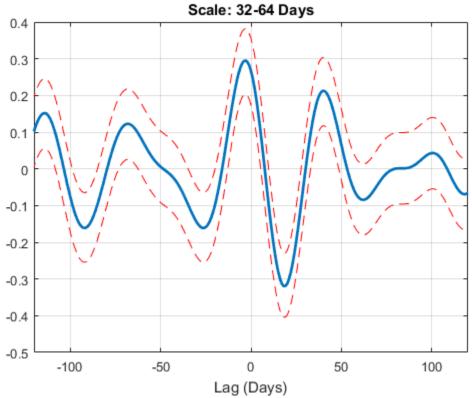

Plot Cross-Correlation Sequences by Lag

Plot the cross-correlation sequence estimate for the Southern Oscillation Index and Truk Island pressure data. Estimate 95% confidence intervals for scale of 2^5 days.

```
load soi
load truk
wsoi = modwt(soi);
wtruk = modwt(truk);
[xcseq,xcseqci,lags] = modwtxcorr(wsoi,wtruk);
plot(lags{5},xcseq{5},'linewidth',2)
```

```
hold on
plot(lags{5},xcseqci{5},'r--')
set(gca,'xlim',[-120 120]);
xlabel('Lag (Days)');
grid
title({'Cross-Correlation Sequence Level 5'; 'Scale: 32-64 Days'});
hold off
```

Cross-Correlation Sequence Level 5

Cross-Correlation with Reflection Boundary

Obtain the MODWT of 36 years of Southern Oscillation Index and Truk Islands pressure data with both periodic and reflection boundary conditions. The modwt with the 'reflection' option extends the input signal symmetrically at the right boundary. The input signal is then twice its original length. MODWTXCORR with the reflection

boundary handling reduces the number of wavelet and scaling coefficients at each half before computing the cross-correlation sequences. The size of the cross-correlation sequences is the same as acquiring the MODWT with the default periodic boundary condition.

```
load soi
load truk
Obtain the MODWT with the default periodic boundary condition.
wsoi default = modwt(soi);
wtruk default = modwt(truk);
Obtain the MODWT with the reflection boundary condition.
wsoi reflect = modwt(soi, 'reflection');
wtruk reflect = modwt(truk, 'reflection');
Obtain the cross correlation sequences.
xcseq default = modwtxcorr(wsoi default, wtruk default);
xcseq reflect = modwtxcorr(wsoi reflect, wtruk reflect, 'reflection');
Compare the number of elements in the cell array output for both boundary conditions.
cellfun(@numel.xcseg reflect)
cellfun(@numel,xcseq default)

```

ans =

"Wavelet Analysis of Financial Data"

Input Arguments

w1 - MODWT transform of signal 1

matrix

MODWT transform of signal 1, specified as a matrix of doubles. The input w1 must be the same size as w2 and must have been obtained with the same wavelet. By default, modwtxcorr assumes that you obtained the MODWT using the symlet wavelet with four vanishing moments, 'sym4').

w2 — MODWT transform of signal 2

matrix

MODWT transform of signal 2, specified as a matrix of doubles. The input w2 must be the same size as w1 and must have been obtained with the same wavelet. By default, modwtxcorr assumes that you obtained the MODWT using the symlet wavelet with four vanishing moments ('sym4').

wav - Wavelet

```
'sym4' (default) | string | positive even integer
```

Wavelet, specified as a string, indicating a valid wavelet, or as a positive even integer indicating the length of the wavelet and scaling filters. If wav is unspecified or specified as an empty, [], wav defaults to 'sym4'.

conflevel — Confidence level

0.95 (default) | positive scalar less than 1

Confidence level, specified as a positive scalar less than 1. conflevel determines the coverage probability of the confidence intervals in xcseqci. If unspecified, or specified as empty, [], conflevel defaults to 0.95.

Output Arguments

xcseq — Cross-correlation sequences by scale

cell array of vectors

Cross-correlation sequences by scale, returned as a cell array of vectors. The vectors are of size 2NJ-by-1, where NJ is the number of nonboundary coefficients by level (scale). This level is the minimum of size(w1,1) and floor(log2(N/(L-1)+1)) where N is the length of the data and L is the filter length. If there are enough nonboundary coefficients at the final level, modwtxcorr returns the scaling cross-correlation sequence estimate in the final cell of xcseq.

xcseqci — Confidence intervals by scale

cell array of matrices

Confidence intervals by scale, returned as a cell array of matrices. The size of each matrix is (2NJ-1)-by-2, where NJ is the number of nonboundary coefficients by level (scale).

- For the .95 default value, the first column of the ith element of xcseqci contains the lower 95% confidence bound for the cross-correlation coefficient at each lag.
- For the .95 default value, the second column contains the upper 95% confidence bound.

Confidence bounds are computed using Fisher's Z-transformation. The standard error of Fisher's Z statistic is the square root of N-3. In this case, N is the equivalent number of coefficients in the critically sampled discrete wavelet transform (DWT), floor(size(w1,2)/2^LEV), where LEV is the level of the wavelet transform. modwtcorr returns NaNs for the confidence bounds when N-3 is less than or equal to zero.

lags - Lags for the cross-correlation sequences

cell array of vectors

Lags for the cross-correlation sequences, returned as a cell array of vectors. lags is a cell array of column vectors the same length as xcseq. The elements in each cell of xcseq

correspond to the cross-correlation sequence estimates at lags from -(NJ-1) to (NJ-1), where NJ is the number of nonboundary coefficients at level J. The 0^{th} lag element is located at the index floor((2*NJ-1)/2)+1.

Introduced in R2015b

morlet

Morlet wavelet

Syntax

```
[PSI,X] = morlet(LB,UB,N)
```

Description

[PSI,X] = morlet(LB,UB,N) returns values of the Morlet wavelet on an N point regular grid in the interval [LB,UB].

Output arguments are the wavelet function PSI computed on the grid X, and the grid X.

This wavelet has [-4 4] as effective support. Although [-4 4] is the correct theoretical effective support, a wider effective support, [-8 8], is used in the computation to provide more accurate results.

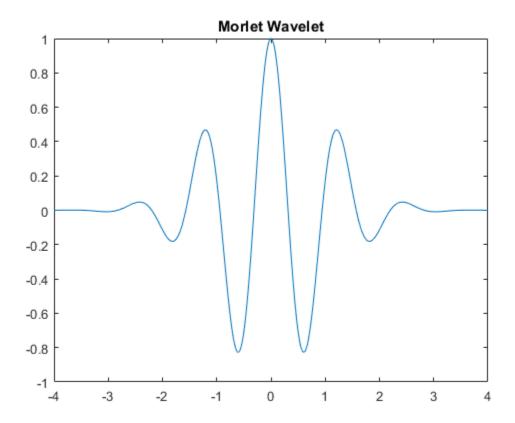

$$\psi(x) = e^{-x^2/2}\cos(5x)$$

Examples

Morlet Wavelet

This example shows how to create a Morlet wavelet. The wavelet has an effective support of [-4,4]. Use 1,000 sample points.

```
lb = -4;
ub = 4;
n = 1000;
[psi,xval] = morlet(lb,ub,n);
plot(xval,psi)
title('Morlet Wavelet');
```

Introduced before R2006a

mswcmp

Multisignal 1-D compression using wavelets

Syntax

```
[XC,DECCMP,THRESH] = mswcmp('cmp',DEC,METH)
[XC,DECCMP,THRESH] = mswcmp('cmp',DEC,METH,PARAM)
[XC,THRESH] = mswcmp('cmpsig',...)
[DECCMP,THRESH] = mswcmp('cmpdec',...)
THRESH = mswcmp('thr',...)
[...] = mswcmp(OPTION,DIRDEC,X,WNAME,LEV,METH)
[...] = mswcmp(OPTION,DIRDEC,X,WNAME,LEV,METH,PARAM)
[...] = mswcmp(...,S_OR_H)
[...] = mswcmp(...,S_OR_H,KEEPAPP)
[...] = mswcmp(...,S_OR_H,KEEPAPP,IDXSIG)
```

Description

mswcmp computes thresholds and, depending on the selected option, performs compression of 1-D signals using wavelets.

```
[XC,DECCMP,THRESH] = mswcmp('cmp',DEC,METH) or
[XC,DECCMP,THRESH] = mswcmp('cmp',DEC,METH,PARAM) returns a compressed
(indicated by 'cmp' input) version XC of the original multisignal matrix X, whose
wavelet decomposition structure is DEC. The output XC is obtained by thresholding the
wavelet coefficients: DECCMP, which is the wavelet decomposition associated with XC (see
mdwtdec), and THRESH is the matrix of threshold values. The input METH is the name of
the compression method and PARAM is the associated parameter, if required.
```

Valid compression methods METH are shown in the following tables. For methods that use an associated parameter, the range of allowable PARAM values is also shown.

'rem_n0'	Remove near 0
'bal_sn'	Balance sparsity-norm

'sqrtbal_sn'	Balance sparsity-norm (sqrt)
'scarce'	Scarce, PARAM (any number)
'scarcehi'	Scarce high, $2.5 \le PARAM \le 10$
'scarceme'	Scarce medium, $1.5 \le PARAM \le 2.5$
'scarcelo'	Scarce low, $1 \le PARAM \le 2$

PARAM is a sparsity parameter, and it should be such that: $1 \le PARAM \le 10$. For scarce method no control is done.

'L2_perf'	Energy ratio
'NO_perf'	Zero coefficients ratio

PARAM is a real number which represents the required performance:

 $0 \le PARAM \le 100$.

'glb_thr'	Global threshold
-----------	------------------

PARAM is a real positive number.

'man_thr'	Manual method
-----------	---------------

PARAM is an NbSIG-by-NbLEV matrix or NbSIG-by-(NbLEV+1) matrix such that:

- - PARAM(i, j) is the threshold for the detail coefficients of level j for the ith signal (1 \leq j \leq NbLEV).
- - PARAM(i, NbLEV+1) is the threshold for the approximation coefficients for the ith signal (if KEEPAPP is 0).

Where NbSIG is the number of signals and NbLEV the number of levels of decomposition.

```
[XC,THRESH] = mswcmp('cmpsig',...) or

[DECCMP,THRESH] = mswcmp('cmpdec',...) or

THRESH = mswcmp('thr',...) Instead of the 'cmp' input OPTION, you can use
'cmpsig', 'cmpdec' or 'thr' to select other output arguments. 'thr' returns the

computed thresholds, but compression is not performed.
```

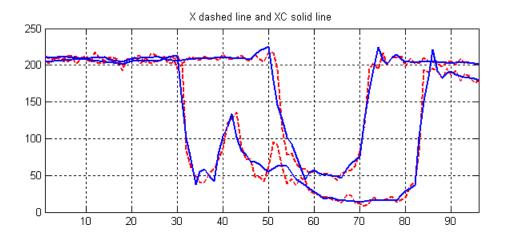

```
[...] = mswcmp(OPTION,DIRDEC,X,WNAME,LEV,METH)
[...] = mswcmp(OPTION,DIRDEC,X,WNAME,LEV,METH,PARAM) The decomposition structure input argument DEC can be replaced by four arguments: DIRDEC, X, WNAME, and LEV. Before performing a compression or computing thresholds, the multisignal matrix X is decomposed at level LEV using the wavelet WNAME, in the direction DIRDEC.
```

```
[...] = mswcmp(...,S_OR_H)
[...] = mswcmp(...,S_OR_H,KEEPAPP)
[...] = mswcmp(...,S_OR_H,KEEPAPP,IDXSIG) Three more optional inputs may be used:
```

- S_OR_H ('s' or 'h') stands for soft or hard thresholding (see mswthresh for more details). Default is 'h'.
- KEEPAPP (true or false) indicates whether to keep approximation coefficients (true) or not (false). Default is false.
- IDXSIG is a vector which contains the indices of the initial signals, or the string 'all'. Default is 'all'.

Examples

```
% Load original 1D-multisignal.
load thinker
% Perform a decomposition at level 2 using wavelet db2.
dec = mdwtdec('r', X, 2, 'db2');
% Compress the signals to obtain a percentage of zeros
% near 95% for the wavelet coefficients.
[XC,decCMP,THRESH] = mswcmp('cmp',dec,'NO perf',95);
[Ecmp, PECcmp, PECFScmp] = wdecenergy(decCMP);
% Plot the original signals 1 and 31, and
% the corresponding compressed signals.
figure;
plot(X([1 31],:)','r--','linewidth',2);
                                           hold on
plot(XC([1 31],:)','b','linewidth',2);
grid; set(gca, 'Xlim', [1,96])
title('X dashed line and XC solid line')
```

Introduced in R2007a

mswcmpscr

Multisignal 1-D wavelet compression scores

Syntax

```
[THR,L2SCR,NOSCR,IDXSORT] = mswcmpscr(DEC)
```

Description

[THR,L2SCR,NOSCR,IDXSORT] = mswcmpscr(DEC) computes four matrices: thresholds THR, compression scores L2SCR and NOSCR, and indices IDXSORT. The decomposition DEC corresponds to a matrix of wavelet coefficients CFS obtained by concatenation of detail and (optionally) approximation coefficients, where

```
CFS = [cd{DEC.level}, ..., cd{1}] or CFS = [ca, cd{DEC.level}, ..., cd{1}]
```

The concatenation is made rowwise if DEC.dirDec is equal to 'r' or columnwise if DEC.dirDec is equal to 'c'.

If NbSIG is the number of original signals and NbCFS the number of coefficients for each signal (all or only the detail coefficients), then CFS is an NbSIG-by-NbCFS matrix. Therefore,

- THR, L2SCR, NOSCR are NbSIG-by-(NbCFS+1) matrices
- IDXSORT is an NbSIG-by-NbCFS matrix
- THR(:,2:end) is equal to CFS sorted by row in ascending order with respect to the absolute value.
- For each row, IDXSORT contains the order of coefficients and THR(:,1)=0.

For the ith signal:

- L2SCR(i,j) is the percentage of preserved energy (L2-norm), corresponding to a threshold equal to CFS(i,j-1) ($2 \le j \le NbCFS$), and L2SCR(:,1)=100.
- NOSCR(i,j) is the percentage of zeros corresponding to a threshold equal to CFS(i,j-1) ($2 \le j \le NbCFS$), and NOSCR(:,1)=0.

Three more optional inputs may be used:

```
[...] = mswcmpscr(...,S_OR_H,KEEPAPP,IDXSIG)
```

- S_OR_H ('s' or 'h') stands for soft or hard thresholding (see mswthresh for more details).
- KEEPAPP (true or false) indicates whether to keep approximation coefficients (true) or not (false).
- IDXSIG is a vector that contains the indices of the initial signals, or the string 'all'.

The defaults are, respectively, 'h', false and 'all'.

Examples

```
% Load original 1D-multisignal.
load thinker
% Perform a decomposition at level 2 using wavelet db2.
dec = mdwtdec('r',X,2,'db2');
% Compute compression performances for soft an hard thresholding.
[THR_S,L2SCR_S,NOSCR_S] = mswcmpscr(dec,'s');
[THR H,L2SCR H,NOSCR H] = mswcmpscr(dec,'h');
```

mswcmptp

Multisignal 1-D compression thresholds and performances

Syntax

```
[THR_VAL,L2_Perf,N0_Perf] = mswcmptp(DEC,METH)
[THR_VAL,L2_Perf,N0_Perf] = mswcmptp(DEC,METH,PARAM)
```

Description

[THR_VAL,L2_Perf,N0_Perf] = mswcmptp(DEC,METH) or [THR_VAL,L2_Perf,N0_Perf] = mswcmptp(DEC,METH,PARAM) computes the vectors THR_VAL, L2_Perf and N0_Perf obtained after a compression using the METH method and, if required, the PARAM parameter (see mswcmp for more information on METH and PARAM).

For the ith signal:

- THR_VAL(i) is the threshold applied to the wavelet coefficients. For a level dependent method, THR_VAL(i,j) is the threshold applied to the detail coefficients at level j
- L2_Perf(i) is the percentage of energy (L2_norm) preserved after compression.
- · NO_Perf(i) is the percentage of zeros obtained after compression.

You can use three more optional inputs:

```
[...] = mswcmptp(...,S_OR_H,KEEPAPP,IDXSIG)
```

- S_OR_H ('s' or 'h') stands for soft or hard thresholding (see mswthresh for more details).
- KEEPAPP (true or false) indicates whether to keep approximation coefficients (true) or not (false)
- IDXSIG is a vector which contains the indices of the initial signals, or the string 'all'.

The defaults are, respectively, 'h', false and 'all'.

Examples

```
% Load original 1D-multisignal.
load thinker

% Perform a decomposition at level 2 using wavelet db2.
dec = mdwtdec('r',X,2,'db2');

% Compute compression thresholds and exact performances
% obtained after a compression using the method 'NO_perf' and
% requiring a percentage of zeros near 95% for the wavelet
% coefficients.
[THR VAL,L2 Perf,NO Perf] = mswcmptp(dec,'NO perf',95);
```

mdwtdec | mdwtrec | ddencmp | wdencmp

Introduced in R2007a

mswden

Multisignal 1-D denoising using wavelets

Syntax

```
[XD,DECDEN,THRESH] = mswden('den',...)
[XD,THRESH] = mswden('densig',...)
[DECDEN,THRESH] = mswden('dendec',...)
THRESH = mswden('thr',...)
[...] = mswden(OPTION,DIRDEC,X,WNAME,LEV,METH,PARAM)
[...] = mswden(...,S_OR_H)
[...] = mswden(...,S_OR_H,KEEPAPP)
[...] = mswden(...,S_OR_H,KEEPAPP,IDXSIG)
```

Description

mswden computes thresholds and, depending on the selected option, performs denoising of 1-D signals using wavelets.

[XD,DECDEN,THRESH] = mswden('den',...) returns a denoised version XD of the original multisignal matrix X, whose wavelet decomposition structure is DEC. The output XD is obtained by thresholding the wavelet coefficients, DECDEN is the wavelet decomposition associated to XD (see mdwtdec), and THRESH is the matrix of threshold values. The input METH is the name of the denoising method and PARAM is the associated parameter, if required.

Valid denoising methods METH and associated parameters PARAM are:

'rigrsure'	Principle of Stein's Unbiased Risk
'heursure'	Heuristic variant of the first option
'sqtwolog'	Universal threshold sqrt(2*log(.))
'minimaxi'	Minimax thresholding (see thselect)

For these methods PARAM defines the multiplicative threshold rescaling:

'one'	No rescaling
'sln'	Rescaling using a single estimation of level noise based on first level coefficients
'mln'	Rescaling using a level dependent estimation of level noise

Penalization methods

'penal'	Penal
'penalhi'	Penal high, 2.5 M≤ PARAM M≤ 10
'penalme'	Penal medium, 1.5 R≤ PARAM R≤ 2.5
'penallo'	Penal low, 1 ℜ≤ PARAM ℜ≤ 2

PARAM is a sparsity parameter, and it should be such that: $1 \le PARAM \le 10$. For penal method, no control is done.

Manual method

'man_thr'	Manual method	
-----------	---------------	--

PARAM is an NbSIG-by-NbLEV matrix or NbSIG-by-(NbLEV+1) matrix such that:

- PARAM(i, j) is the threshold for the detail coefficients of level j for the ith signal (1 ≤ j ≤ NbLEV).
- PARAM(i, NbLEV+1) is the threshold for the approximation coefficients for the ith signal (if KEEPAPP is 0).

where \mbox{NbSIG} is the number of signals and \mbox{NbLEV} the number of levels of decomposition.

Instead of the 'den' input OPTION, you can use 'densig', 'dendec' or 'thr' OPTION to select output arguments:

```
[XD,THRESH] = mswden('densig',...) or [DECDEN,THRESH] = mswden('dendec',...)
```

THRESH = mswden('thr',...) returns the computed thresholds, but denoising is not performed.

The decomposition structure input argument DEC can be replaced by four arguments: DIRDEC, X, WNAME and LEV.

[...] = mswden(OPTION, DIRDEC, X, WNAME, LEV, METH, PARAM) before performing a denoising or computing thresholds, the multisignal matrix X is decomposed at level LEV using the wavelet WNAME, in the direction DIRDEC.

You can use three more optional inputs:

```
[...] = mswden(...,S_OR_H) or
[...] = mswden(...,S_OR_H,KEEPAPP) or
[...] = mswden(...,S_OR_H,KEEPAPP,IDXSIG)
```

- S_OR_H ('s' or 'h') stands for soft or hard thresholding (see mswthresh for more details).
- KEEPAPP (true or false) indicates whether to keep approximation coefficients (true) or not (false).
- IDXSIG is a vector that contains the indices of the initial signals, or the string 'all'.

The defaults are, respectively, 'h', false and 'all'.

Examples

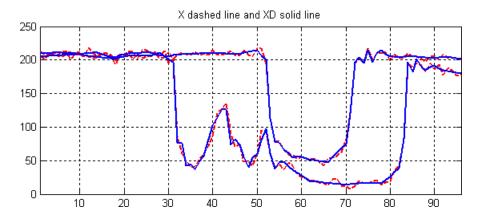

```
% Load original 1D-multisignal.
load thinker

% Perform a decomposition at level 2 using the wavelet db2.
dec = mdwtdec('r',X,2,'db2');

% Denoise signals using the universal method
% of thresholding (sqtwolog) and the 'sln'
% threshold rescaling (with a single estimation
% of level noise, based on first level coefficients).
[XD,decDEN,THRESH] = mswden('den',dec,'sqtwolog','sln');

% Plot the original signals 1 and 31, and the
% corresponding denoised signals.
figure;
plot(X([1 31],:)','r--','linewidth',2); hold on
plot(XD([1 31],:)','b','linewidth',2);
```

grid; set(gca,'Xlim',[1,96])
title('X dashed line and XD solid line')

mswthresh

Perform multisignal 1-D thresholding

Syntax

```
Y = mswthresh(X,SORH,T)
Y = mswthresh(X,SORH,T,'c')
Y = mswthresh(X,'s',T)
Y = mswthresh(X,'h',T)
```

Description

```
Y = mswthresh(X, SORH, T) returns soft (if SORH='s') or hard (if SORH='h') T-thresholding of the input matrix X. T can be a single value, a matrix of the same size as X or a vector. In this last case, thresholding is performed rowwise and LT = length(T) must be such that Size(X, 1) \leq LT.
```

```
Y = mswthresh(X,SORH,T,'c') performs a columnwise thresholding and size(X,2) \leq LT.
```

```
Y = mswthresh(X, 's', T) returns Y = SIGN(X).(|X|-T)+, soft thresholding is shrinkage.
```

```
Y = mswthresh(X, 'h', T) returns Y = X.1_(|X|>T), hard thresholding is cruder.

Syntax

```
A = nodeasc(T, N)
```

Description

nodeasc is a tree-management utility.

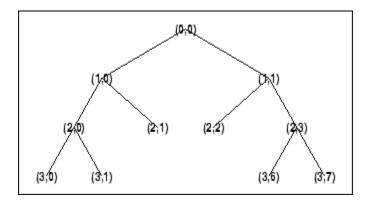

A = nodeasc(T,N) returns the indices of all the ascendants of the node N in the tree T where N can be the index node or the depth and position of the node. A is a column vector with A(1) = index of node N.

A = nodeasc(T,N, 'deppos') is a matrix, which contains the depths and positions of all ascendants. A(i,1) is the depth of the i-th ascendant and A(i,2) is the position of the i-th ascendant.

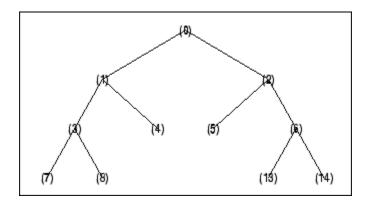

The nodes are numbered from left to right and from top to bottom. The root index is 0.

Examples

```
% Create binary tree of depth 3.
t = ntree(2,3);
t = nodejoin(t,5);
t = nodejoin(t,4);
plot(t)
```

% Change Node Label from Depth_Position to Index % (see the plot function).

```
nodeasc(t,[2 2])
ans =
    5
    2
    0

nodeasc(t,[2 2],'deppos')
ans =
    2    2
    1    1
    0    0

nodedesc

Node descendants

Syntax

```
D = nodedesc(T,N)
D = nodedesc(T,N,'deppos')
```

Description

nodedesc is a tree-management utility.

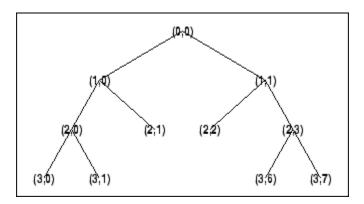

D = nodedesc(T,N) returns the indices of all the descendants of the node N in the tree T where N can be the index node or the depth and position of node. D is a column vector with D(1) = index of node N.

D = nodedesc(T,N, 'deppos') is a matrix that contains the depths and positions of all descendants. D(i,1) is the depth of the i-th descendant and D(i,2) is the position of the i-th descendant.

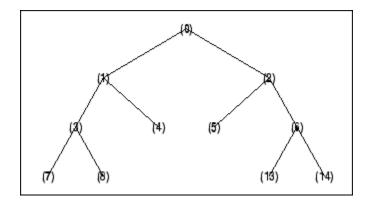

The nodes are numbered from left to right and from top to bottom. The root index is 0.

Examples

```
% Create binary tree of depth 3.
t = ntree(2,3);
t = nodejoin(t,5);
t = nodejoin(t,4);
plot(t)
```

% Change Node Label from Depth_Position to Index % (see the plot function).

nodejoin

Recompose node

Syntax

```
T = nodejoin(T,N)
T = nodejoin(T)
T = nodejoin(T,0)
```

Description

nodejoin is a tree-management utility.

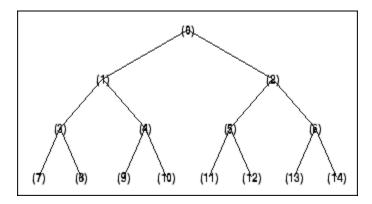

T = nodejoin(T, N) returns the modified tree T corresponding to a recomposition of the node N.

The nodes are numbered from left to right and from top to bottom. The root index is 0.

```
T = nodejoin(T) is equivalent to T = nodejoin(T, 0).
```

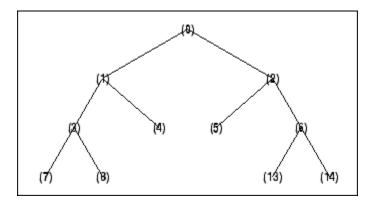

Examples

```
% Create binary tree of depth 3.
t = ntree(2,3);
% Plot tree t.
plot(t)
% Change Node Label from Depth_Position to Index
% (see the plot function).
```

```
% Merge nodes of indices 4 and 5.
t = nodejoin(t,5);
t = nodejoin(t,4);
% Plot new tree t.
plot(t)
```

% Change Node Label from Depth_Position to Index % (see the plot function).

See Also nodesplt

Introduced before R2006a

nodepar

Node parent

Syntax

```
F = nodepar(T,N)
F = nodepar(T,N,'deppos')
```

Description

nodepar is a tree-management utility.

F = nodepar(T, N) returns the indices of the Äúparent(s)Äù of the nodes N in the tree T where N can be a column vector containing the indices of nodes or a matrix that contains the depths and positions of nodes. In the last case, N(i, 1) is the depth of the i-th node and N(i, 2) is the position of the i-th node.

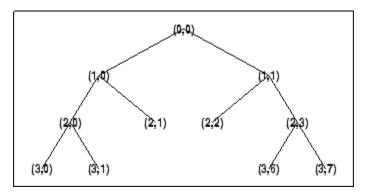

F = nodepar(T,N, 'deppos') is a matrix that contains the depths and positions of returned nodes. F(i,1) is the depth of the i-th node and F(i,2) is the position of the i-th node.

```
nodepar(T,0) or nodepar(T,[0,0]) returns -1.
nodepar(T,0,'deppos') or nodepar(T,[0,0],'deppos') returns [-1,0].
```

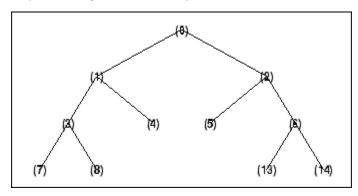

The nodes are numbered from left to right and from top to bottom. The root index is 0.

Examples

```
% Create binary tree of depth 3.
t = ntree(2,3);
t = nodejoin(t,5);
t = nodejoin(t,4);
plot(t)
```

% Change Node Label from Depth_Position to Index % (see the plot function).

nodesplt

Split (decompose) node

Syntax

```
T = nodesplt(T, N)
```

Description

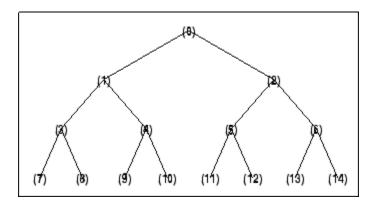

nodesplt is a tree-management utility.

T = nodesplt(T, N) returns the modified tree T corresponding to the decomposition of the node N.

The nodes are numbered from left to right and from top to bottom. The root index is 0.

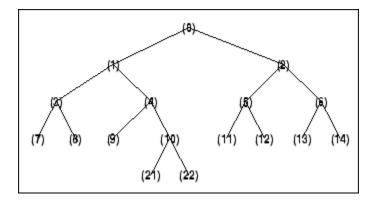

Examples

```
% Create binary tree (tree of order 2) of depth 3.
t = ntree(2,3);
% Plot tree t.
plot(t)
% Change Node Label from Depth_Position to Index
% (see the plot function).
```

```
% Split node of index 10.
t = nodesplt(t,10);
```

- % Plot new tree t. plot(t)
- % Change Node Label from Depth_Position to Index % (see the plot function).

Introduced before R2006a

noleaves

Determine nonterminal nodes

Syntax

```
N = noleaves(T)
N = noleaves(T, 'dp')
```

Description

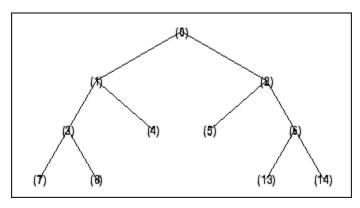

N = noleaves(T) returns the indices of nonterminal nodes of the tree T (i.e., nodes that are not leaves). N is a column vector.

The nodes are ordered from left to right as in tree *T*.

N = noleaves(T, 'dp') returns a matrix N, which contains the depths and positions of nonterminal nodes.

```
N(i,1) is the depth of the i-th nonterminal node and N(i,2) is the position of the i-th nonterminal node.
```

Examples

```
% List nonterminal nodes (index).
ntnodes_ind = noleaves(t)
ntnodes_ind =
     0
     1
     2
     3
     6
% List nonterminal nodes (Depth_Position).
ntnodes_depo = noleaves(t,'dp')
ntnodes_depo =
     0
           0
     1
           0
     1

ntnode

Number of terminal nodes

Syntax

NB = ntnode(T)

Description

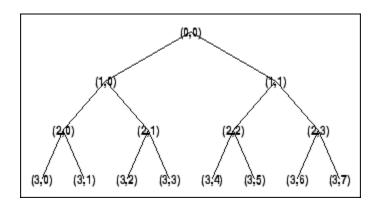

ntnode is a tree-management utility.

NB = ntnode(T) returns the number of terminal nodes in the tree T.

The nodes are numbered from left to right and from top to bottom. The root index is 0.

Examples

```
% Create binary tree (tree of order 2) of depth 3.
t = ntree(2,3);
% Plot tree t.
plot(t)
```

```
% Number of terminal nodes.
ntnode(t)
ans =
   8
```

wtreemgr

Introduced before R2006a

ntree

NTREE constructor

Syntax

```
T = ntree(ORD,D)
T = ntree
T = ntree(2,0)
T = ntree(ORD)
T = ntree(ORD,0)
T = ntree(ORD,D,S)
T = ntree(ORD,D,S,U)
```

Description

T = ntree(ORD, D) returns an NTREE object, which is a complete tree of order ORD and depth D.

```
T = ntree is equivalent to T = ntree(2,0).

T = ntree(ORD) is equivalent to T = ntree(ORD,0).
```

With T = ntree(ORD,D,S) you can set a "split scheme" for nodes. The split scheme field S is a logical array of size ORD by 1.

The root of the tree can be split and it has ORD children. You can split the j-th child if S(j) = 1.

Each node that you can split has the same property as the root node.

With T = ntree(ORD,D,S,U) you can, in addition, set a userdata field.

Inputs can be given in another way:

```
T = ntree('order', ORD, 'depth', D, 'spsch', S, 'ud', U). For "missing" inputs the defaults are ORD = 2 and D = 0, S = ones([1:ORD]), U = \{\}.
```

[T,NB] = ntree(...) returns also the number of terminal nodes (leaves) of T.

For more information on object fields, type help <code>ntree/get</code>.

Class NTREE (Parent class: WTBO)

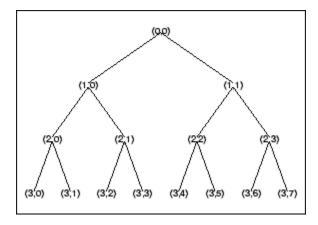

Fields

wtbo	Parent object
order	Tree order
depth	Tree depth
spsch	Split scheme for nodes
tn	Column vector with terminal node indices

Examples

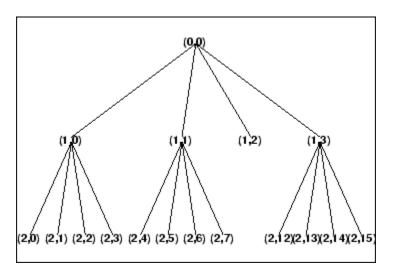

```
% Create binary tree (tree of order 2) of depth 3. t2 = ntree(2,3);
```

% Plot tree t2. plot(t2)

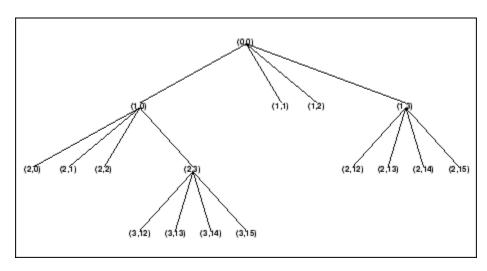

% Create a quadtree (tree of order 4) of depth 2.

```
t4 = ntree(4,2,[1 1 0 1]);
% Plot tree t4.
plot(t4)
```

- % Split and merge some nodes using the gui
- % generated by plot (see the plot function).
- % The figure becomes:

Introduced before R2006a

orthfilt

Orthogonal wavelet filter set

Syntax

Description

[Lo_D,Hi_D,Lo_R,Hi_R] = orthfilt(W) computes the four filters associated with the scaling filter W corresponding to a wavelet:

Lo_D	Decomposition low-pass filter
Hi_D	Decomposition high-pass filter
Lo_R	Reconstruction low-pass filter
Hi_R	Reconstruction high-pass filter

For an orthogonal wavelet, in the multiresolution framework, we start with the scaling function φ and the wavelet function ψ . One of the fundamental relations is the twin-scale relation:

$$\frac{1}{2}\phi\bigg(\frac{x}{2}\bigg) = \sum_{n \in Z} w_n \phi(x-n)$$

All the filters used in dwt and idwt are intimately related to the sequence $(w_n)_{n\in \mathbb{Z}}$. Clearly if ϕ is compactly supported, the sequence (w_n) is finite and can be viewed as a FIR filter. The scaling filter \mathbb{W} is

- A low-pass FIR filter
- Of length 2N
- Of sum 1

Of norm
$$\frac{1}{\sqrt{2}}$$

For example, for the db3 scaling filter,

```
load db3
db3
db3 =
     0.2352 0.5706 0.3252 -0.0955 -0.0604 0.0249

sum(db3)
ans =
     1.000
     norm(db3)
ans =
     0.7071
```

From filter W, we define four FIR filters, of length 2N and norm 1, organized as follows:

Filters	Low-Pass	High-Pass
Decomposition	Lo_D	Hi_D
Reconstruction	Lo_R	Hi_R

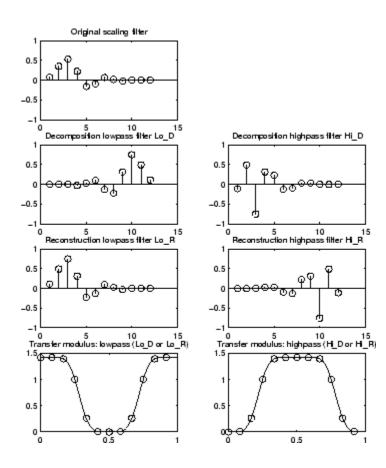

The four filters are computed using the following scheme:

where qmf is such that Hi_R and Lo_R are quadrature mirror filters (i.e., Hi_R(k) = $(-1)^k$ Lo_R(2N + 1 - k), for k = 1, 2, Ä, 2N), and where wrev flips the filter coefficients. So Hi_D and Lo_D are also quadrature mirror filters. The computation of these filters is performed using orthfilt.

Examples

```
% Load scaling filter.
load db8; w = db8;
subplot(421); stem(w);
title('Original scaling filter');
% Compute the four filters.
[Lo D,Hi D,Lo R,Hi R] = orthfilt(w);
subplot(423); stem(Lo_D);
title('Decomposition low-pass filter');
subplot(424); stem(Hi D);
title('Decomposition high-pass filter');
subplot(425); stem(Lo R);
title('Reconstruction low-pass filter');
subplot(426); stem(Hi R);
title('Reconstruction high-pass filter');
% Check for orthonormality.
df = [Lo_D; Hi_D];
rf = [Lo_R;Hi_R];
id = df*df'
id =
    1.0000
              1.0000
id = rf*rf'
id =
    1.0000
              1.0000
         0
% Check for orthogonality by dyadic translation, for example:
df = [Lo D O O; Hi D O O];
dft = [0 0 Lo_D; 0 0 Hi_D];
zer = df*dft'
zer =
    1.0e-12 *
    -0.1883 0.0000
    -0.0000 -0.1883
```

```
% High- and low-frequency illustration.
fftld = fft(Lo_D); ffthd = fft(Hi_D);
freq = [1:length(Lo_D)]/length(Lo_D);
subplot(427); plot(freq,abs(fftld));
title('Transfer modulus: low-pass');
subplot(428); plot(freq,abs(ffthd));
title('Transfer modulus: high-pass')
% Editing some graphical properties,
% the following figure is generated.
```

Introduced before R2006a

otnodes

Order terminal nodes of binary wavelet packet tree

Syntax

```
[Tn_Pal,Tn_Seq] = otnodes(WPT)
[Tn_Pal,Tn_Seq,I,J] = otnodes(WPT)
[DP Pal,DP Seq] = otnodes(WPT,'dp')
```

Description

[Tn_Pal,Tn_Seq] = otnodes(WPT) returns the terminal nodes of the binary wavelet packet tree, WPT, in Paley (natural) ordering, Tn_Pal, and sequency (frequency) ordering, Tn_Seq. Tn_Pal and Tn_Seq are *N*-by-1 column vectors where *N* is the number of terminal nodes.

```
[Tn_Pal,Tn_Seq,I,J] = otnodes(WPT) returns the permutations of the terminal node indices such that Tn_Seq = Tn_Pal(I) and Tn_Pal = Tn_Seq(J).
```

[DP_Pal,DP_Seq] = otnodes (WPT, 'dp') returns the Paley and frequency-ordered terminal nodes in node depth-position format. DP_Pal and DP_Seq are N-by-2 matrices. The first column contains the depth index, and the second column contains the position index.

Input Arguments

WPT

Binary wavelet packet tree. You can use treeord to determine the order of your wavelet packet tree.

dp

String variable indicating that the Paley-ordered or sequency-ordered nodes are returned in depth-position format.

Output Arguments

Tn_Pal

Terminal nodes in Paley (natural) ordering

Tn_Seq

Terminal nodes in sequency ordering

DP_Pal

Paley-ordered terminal nodes in depth-position format. This output argument only applies when you use the 'dp' input argument.

DP_Seq

Sequency-ordered terminal nodes in depth-position format. This output argument only applies when you use the 'dp' input argument.

Examples

Order terminal nodes with Paley and frequency ordering:

```
x = randn(8,1);
wpt = wpdec(x,2,'haar');
[Tn_Pal,Tn_Seq] = otnodes(wpt);
% Tn_Pal is [3 4 5 6]
% Tn_Seq is [3 4 6 5]
```

Return permutations for Paley and frequency ordering:

```
load noisdopp;
wpt = wpdec(noisdopp,6,'sym4');
[Tn_Pal,Tn_Seq,I,J] = otnodes(wpt);
isequal(Tn_Seq(J),Tn_Pal)
isequal(Tn_Seq,Tn_Pal(I))
```

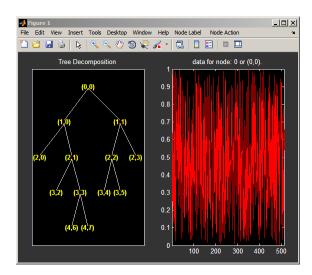

Order terminal nodes by depth and position:

```
x = randn(8,1);
```

```
wpt = wpdec(x,2,'haar');
[DP_Pal,DP_Seq] = otnodes(wpt,'dp');
```

Order terminal nodes from a modified wavelet packet tree:

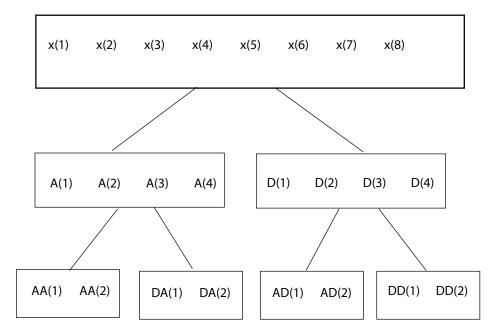

```
t = wptree(2,2,rand(1,512),'haar');
t = wpsplt(t,4);
t = wpsplt(t,5);
t = wpsplt(t,10);
plot(t);
[tn_Pal,tn_Seq,I,J] = otnodes(t);
```

More About

Paley (Natural) and Sequency (Frequency) Ordering

The discrete wavelet packet transform iterates on both approximation and detail coefficients at each level. In this transform, A denotes the lowpass (approximation) filter followed by downsampling. D denotes the highpass (detail) filter followed by downsampling. The following figure represents a wavelet packet transform in Paley ordering acting on a time series of length 8. The transform has a depth of two.

Because of aliasing introduced by downsampling, the frequency content extracted by the operator AD is higher than the frequency content extracted by the DD operator. Therefore, the terminal nodes in frequency (sequency) order are: AA,DA,DD,AD. The terminal nodes in Paley order have the following indices: 3,4,5,6. The frequency order has the indices: 3,4,6,5.

Introduced in R2010b

pat2cwav

Build wavelet from pattern

Syntax

```
[PSI,XVAL,NC] = pat2cwav(YPAT,METHOD,POLDEGREE,REGULARITY)
```

Description

[PSI, XVAL, NC] = pat2cwav(YPAT, METHOD, POLDEGREE, REGULARITY) computes an admissible wavelet for CWT (given by XVAL and PSI) adapted to the pattern defined by the vector YPAT, and of norm equal to 1.

The underlying x-values pattern is set to

```
xpat = linspace(0,1,length(YPAT))
```

The constant NC is such that NC*PSI approximates YPAT on the interval [0,1] by least squares fitting using

- a polynomial of degree POLDEGREE when METHOD is equal to 'polynomial'
- a projection on the space of functions orthogonal to constants when METHOD is equal to 'orthconst'

The REGULARITY parameter defines the boundary constraints at the points 0 and 1. Allowable values are 'continuous', 'differentiable', and 'none'.

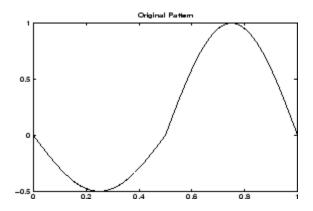

When METHOD is equal to 'polynomial'

- if REGULARITY is equal to 'continuous', POLDEGREE must be greater than or equal to 3.
- if REGULARITY is equal to 'differentiable', POLDEGREE must be greater than or equal to 5.

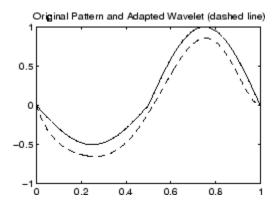

Examples

The principle for designing a new wavelet for CWT is to approximate a given pattern using least squares optimization under constraints leading to an admissible wavelet well suited for the pattern detection using the continuous wavelet transform (see Misiti et al.).

```
load ptpssin1;
plot(X,Y), title('Original Pattern')
```

```
[psi,xval,nc] = pat2cwav(Y, 'polynomial',6, 'continuous') ;
plot(X,Y,'-',xval,nc*psi,'--'),
title('Original Pattern and Adapted Wavelet (dashed line)')
```

You can check that psi satisfies the definition of a wavelet by noting that it integrates to zero and that its L_2 norm is equal to 1.

```
dx = xval(2)-xval(1);
Mu = sum(psi*dx)
L2norm = sum(abs(psi).^2*dx)
```

Introduced before R2006a

plot

Plot tree GUI

Syntax

```
plot(T)
plot(T,FIG)
```

Description

plot is a graphical tree-management utility.

```
plot(T) plots the tree T.
```

The figure that contains the tree is a GUI tool. It lets you change the **Node Label** to **Depth_Position** or **Index**, and **Node Action** to **Split-Merge** or **Visualize**.

The default values are **Depth_Position** and **Visualize**.

You can click the nodes to execute the current **Node Action**.

plot(T, FIG) plots the tree T in the figure whose handle is FIG. This figure was already used to plot a tree, for example using the command

```
FIG = plot(T)
```

After some split or merge actions, you can get the new tree using its parent figure handle. The following syntax lets you perform this functionality:

```
NEWT = plot(T, 'read', FIG)
```

In fact, the first argument is dummy. The most general syntax is

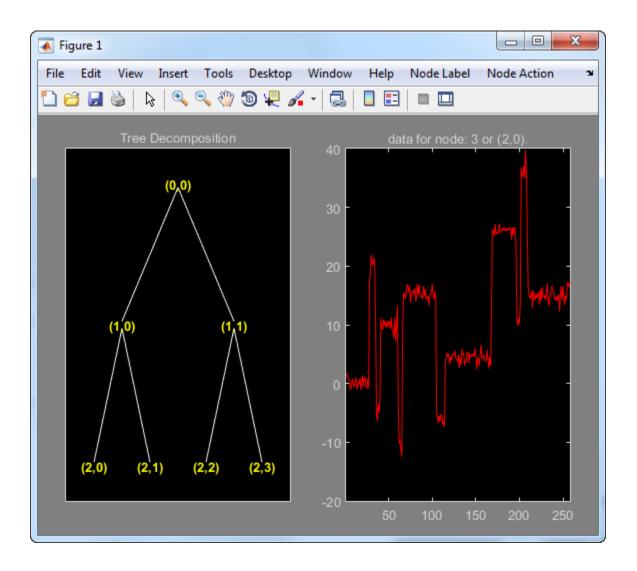

```
NEWT = plot(DUMMY, 'read', FIG)
```

where DUMMY is any object parented by an NTREE object. More generally, DUMMY can be any object constructor name returning an NTREE parented object. For example:

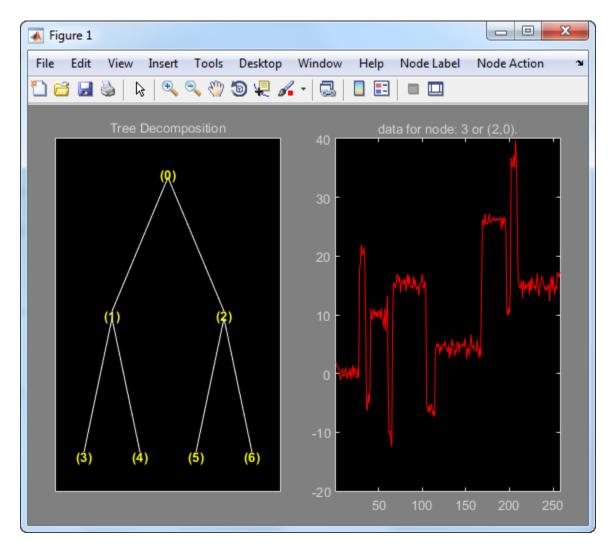

```
NEWT = plot(ntree, 'read',FIG)
NEWT = plot(dtree, 'read',FIG)
NEWT = plot(wptree, 'read',FIG)
```

Examples

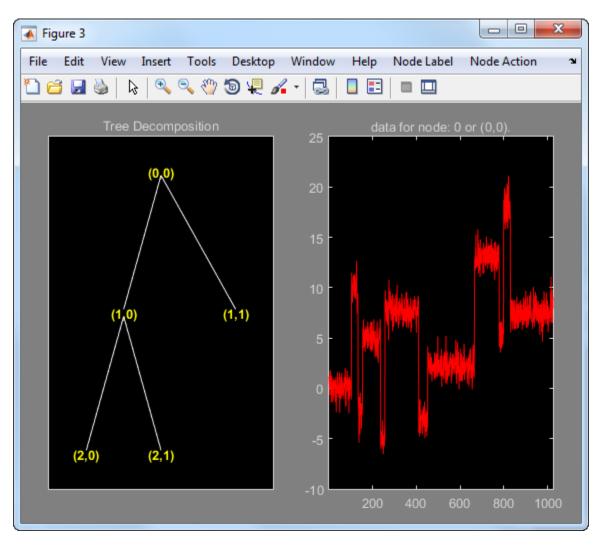

```
% Create a wavelet packets tree (1-D)
load noisbloc
x = noisbloc;
t = wpdec(x,2,'db2');
% Plot tree t.
plot(t)
```

- % Change Node Label from Depth_Position to Index.
- % Click the node (3). You get the following figure.

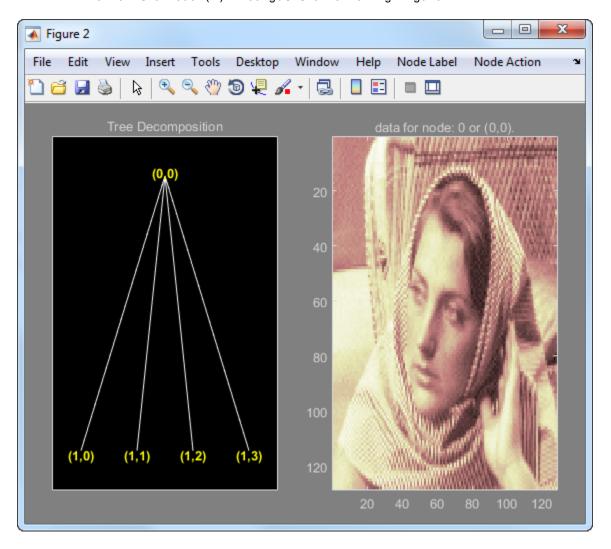

Now set the **Node Label** back to **Depth_Position**. Change **Node Action** to **Split-Merge**. Click on the (1,1) node.

The above figure now shows the discrete wavelet transform down to level 2.

```
% Create a wavelet packets tree (2-D)
load woman2
t = wpdec2(X,1,'sym4');
% Plot tree t.
plot(t)
```

- % Change Node Label from Depth_Position to Index. % Click the node (1). You get the following figure.

Introduced before R2006a

plotdt

Plot dual-tree or double-density wavelet transform

Syntax

```
plotdt(wt)
```

Description

plotdt(wt) plots the coefficients of the 1-D or 2-D wavelet filter bank decomposition, wt.

Examples

Plot Complex Dual-Tree Wavelet Transform of 1-D Signal

Plot the complex dual-tree wavelet transform of the noisy Doppler signal.

Load the noisy Doppler signal. Obtain the complex dual-tree wavelet transform down to level 4.

```
load noisdopp;
wt = dddtree('cplxdt',noisdopp,4,'dtf1');
Plot the coefficients.
plotdt(wt)
```

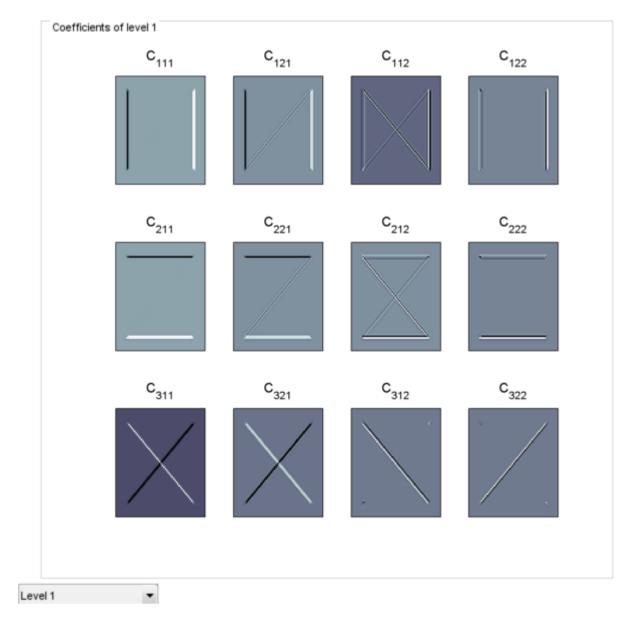

Plot Complex Oriented Dual-Tree Wavelet Transform of 2-D Image

Plot the complex oriented dual-tree wavelet transform of an image.

Load the "xbox" image. Obtain the complex oriented dual-tree wavelet transform down to level 3.

```
load xbox;
wt = dddtree2('cplxdt',xbox,3,'dtf1');
Plot the coefficients.
plotdt(wt)
```

Select the level-one detail coefficients from the drop-down list in the lower left corner.

"Analytic Wavelets Using the Dual-Tree Wavelet Transform"

Input Arguments

wt — Wavelet transform

structure

Wavelet transform, returned as a structure from dddtree or dddtree2 with these fields:

type — Type of wavelet decomposition (filter bank)

```
'dwt' | 'ddt' | 'realdt' | 'cplxdt' | 'realdddt' | 'cplxdddt'
```

Type of wavelet decomposition (filter bank), specified as one of 'dwt', 'ddt', 'realdt', 'cplxdt', 'realddt', or 'cplxdddt'. 'realdt' and 'realdddt' are only valid for the 2-D wavelet transform. The type, 'dwt', is a critically sampled (nonredundant) discrete wavelet transform for 1-D data or 2-D images. The other decomposition types are oversampled wavelet transforms. For details about transform types see dddtree for 1-D wavelet transforms and dddtree2 for 2-D wavelet transforms.

1evel — Level of the wavelet decomposition

positive integer

Level of the wavelet decomposition, specified as a positive integer.

filters — Decomposition (analysis) and reconstruction (synthesis) filters

structure

Decomposition (analysis) and reconstruction (synthesis) filters, specified as a structure with these fields:

Fdf — First-stage analysis filters

matrix | cell array

First level decomposition filters specified as an *N*-by-2 or *N*-by-3 matrix for single-tree wavelet transforms, or a 1-by-2 cell array of two *N*-by-2 or *N*-by-3 matrices for dual-tree wavelet transforms. The matrices are *N*-by-3 for the double-density wavelet transforms. For an *N*-by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an *N*-by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the first-stage analysis filters for the corresponding tree.

Df — Analysis filters for levels > 1

matrix | cell array

Analysis filters for levels > 1, specified as an N-by-2 or N-by-3 matrix for single-tree wavelet transforms, or a 1-by-2 cell array of two N-by-2 or N-by-3 matrices for dual-tree wavelet transforms. The matrices are N-by-3 for the double-density wavelet transforms. For an N-by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N-by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the analysis filters for the corresponding tree.

Frf — First-level reconstruction filters

matrix | cell array

First-level reconstruction filters, specified as an *N*-by-2 or *N*-by-3 matrix for single-tree wavelet transforms, or a 1-by-2 cell array of two *N*-by-2 or *N*-by-3 matrices for dual-tree wavelet transforms. The matrices are *N*-by-3 for the double-density wavelet transforms. For an *N*-by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an *N*-by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the first-stage synthesis filters for the corresponding tree.

Rf — Reconstruction filters for levels > 1

matrix | cell array

Reconstruction filters for levels > 1, specified as an N-by-2 or N-by-3 matrix for single-tree wavelet transforms, or a 1-by-2 cell array of two N-by-2 or N-by-3 matrices for dual-tree wavelet transforms. The matrices are N-by-3 for the double-density wavelet transforms. For an N-by-2 matrix, the first column of the matrix is the scaling (lowpass) filter and the second column is the wavelet (highpass) filter. For an N-by-3 matrix, the first column of the matrix is the scaling (lowpass) filter and the second and third columns are the wavelet (highpass) filters. For the dual-tree transforms, each element of the cell array contains the first-stage synthesis filters for the corresponding tree.

cfs — Wavelet transform coefficients

cell array of matrices

Wavelet transform coefficients, specified as a 1-by-(level+1) cell array of matrices. The size and structure of the matrix elements of the cell array depend on the type of wavelet transform and whether the decomposition is 1-D or 2-D. For a 1-D wavelet transform, the coefficients are organized by transform type as follows:

'dwt' — cfs{j}

- j = 1,2,...level is the level.
- cfs{level+1} are the lowpass, or scaling, coefficients.
- 'ddt' cfs{j}(:,:,k)
 - j = 1,2,... level is the level.
 - k = 1,2 is the wavelet filter.
 - $cfs{level+1}(:,:)$ are the lowpass, or scaling, coefficients.
- 'cplxdt' cfs{j}(:,:,m)
 - j = 1,2,... level is the level.
 - m = 1,2 are the real and imaginary parts.
 - cfs{level+1}(:,:) are the lowpass, or scaling, coefficients.
- 'realdddt' cfs{j}(:,:,d,k)
 - j = 1,2,... level is the level.
 - d = 1,2,3 is the orientation.
 - k = 1,2 is the wavelet transform tree.
 - cfs{level+1}(:,:) are the lowpass, or scaling, coefficients.
- 'cplxdddt' cfs ${j}(:,:,d,k,m)$
 - j = 1,2,... level is the level.
 - k = 1,2 is the wavelet transform tree.
 - m = 1,2 are the real and imaginary parts.
 - $cfs{level+1}(:,:)$ are the lowpass, or scaling, coefficients.

For a 2-D wavelet transform, the coefficients are organized by transform type as follows:

- 'dwt' cfs{j}(:,:,d)
 - j = 1,2,... level is the level.
 - d = 1,2,3 is the orientation.
 - cfs{level+1}(:,:) are the lowpass, or scaling, coefficients.
- 'ddt' cfs{j}(:,:,d)
 - j = 1,2,... level is the level.

- d = 1,2,3,4,5,6,7,8 is the orientation.
- $cfs{level+1}(:,:)$ are the lowpass, or scaling, coefficients.
- 'realddt' cfs{j}(:,:,d,k)
 - j = 1,2,... level is the level.
 - d = 1,2,3 is the orientation.
 - k = 1,2 is the wavelet transform tree.
 - $cfs{level+1}(:,:)$ are the lowpass, or scaling, coefficients.
- 'cplxdt' cfs{j}(:,:,d,k,m)
 - j = 1,2,... level is the level.
 - d = 1,2,3 is the orientation.
 - k = 1,2 is the wavelet transform tree.
 - m = 1,2 are the real and imaginary parts.
 - cfs{level+1}(:,:) are the lowpass, or scaling, coefficients.
- 'realdddt' cfs{j}(:,:,d,k)
 - j = 1,2,... level is the level.
 - d = 1,2,3 is the orientation.
 - k = 1,2 is the wavelet transform tree.
 - cfs{level+1}(:,:) are the lowpass, or scaling, coefficients.
- 'cplxdddt' cfs{j}(:,:,d,k,m)
 - j = 1,2,... level is the level.
 - d = 1,2,3 is the orientation.
 - k = 1,2 is the wavelet transform tree.
 - m = 1,2 are the real and imaginary parts.
 - cfs{level+1}(:,:) are the lowpass, or scaling, coefficients.

Introduced in R2013b

qmf

Scaling and Wavelet Filter

Syntax

Y = qmf(X,P) Y = qmf(X)Y = qmf(X,0)

Description

Y = qmf(X,P) changes the signs of the even index entries of the reversed vector filter coefficients X if P is even. If P is odd the same holds for odd index entries. Y = qmf(X) is equivalent to Y = qmf(X,0).

Let x be a finite energy signal. Two filters F_0 and F_1 are quadrature mirror filters (QMF) if, for any x,

$$\|y_0\|^2 + \|y_1\|^2 = \|x\|^2$$

where y_0 is a decimated version of the signal x filtered with F_0 so y_0 defined by $x_0 = F_0(x)$ and $y_0(n) = x_0(2n)$, and similarly, y_1 is defined by $x_1 = F_1(x)$ and $y_1(n) = x_1(2n)$. This property ensures a perfect reconstruction of the associated two-channel filter banks scheme (see Strang-Nguyen p. 103).

For example, if F_0 is a Daubechies scaling filter and $F_1 = \mathsf{qmf}(F_0)$, then the transfer functions $F_0(z)$ and $F_1(z)$ of the filters F_0 and F_1 satisfy the condition (see the example for db10):

$$|F_0(z)|^2 + |F_1(z)|^2 = 1$$

Examples

% Load scaling filter associated with an orthogonal wavelet. load db10;

```
subplot(321); stem(db10); title('db10 low-pass filter');
% Compute the quadrature mirror filter.
qmfdb10 = qmf(db10);
subplot(322); stem(qmfdb10); title('QMF db10 filter');
% Check for frequency condition (necessary for orthogonality):
% abs(fft(filter))^2 + abs(fft(qmf(filter))^2 = 1 at each
% frequency.
m = fft(db10);
mt = fft(qmfdb10);
freq = [1:length(db10)]/length(db10);
subplot(323); plot(freq,abs(m));
title('Transfer modulus of db10')
subplot(324); plot(freq,abs(mt));
title('Transfer modulus of QMF db10')
subplot(325); plot(freq,abs(m).^2 + abs(mt).^2);
title('Check QMF condition for db10 and QMF db10')
xlabel('abs(fft(db10))^2 + abs(fft(qmf(db10))^2 = 1')
% Editing some graphical properties,
% the following figure is generated.

rbiowavf

Reverse biorthogonal spline wavelet filters

Syntax

```
[RF,DF] = rbiowavf(W)
```

Description

[RF,DF] = rbiowavf(W) returns the two scaling filters associated with the biorthogonal wavelet specified by the string W.

W = 'rbioNd.Nr' where possible values for Nd and Nr are

The output arguments are filters.

- RF is the reconstruction filter.
- · DF is the decomposition filter.

Reverse Biorthgonal Scaling Filter

Obtain the reverse biorthogonal reconstruction and decomposition scaling filters for the 'rbio3.1' wavelet. The 'rbio3.1' wavelet has 3 vanishing moments for the decomposition (analysis) wavelet and 1 vanishing moment for the reconstruction (synthesis) wavelet.

```
[RF,DF] = rbiowavf('rbio3.1');
```

The reconstruction scaling filter, RF, and the decomposition filter, DF, are equal to the filters returned by wfilters scaled by $\sqrt{2}$.

```
[LoD, HiD, LoR, HiR] = wfilters('rbio3.1');
max(abs(sqrt(2)*DF-LoD))
max(abs(sqrt(2)*RF-LoR))

ans =
    0

ans =
    0
```

read

Read values of WPTREE

Syntax

VARARGOUT = read(T, VARARGIN)

Description

VARARGOUT = read(T, VARARGIN) is the most general syntax to read one or more property values from the fields of a WPTREE object.

The different ways to call the read function are

```
PropValue = read(T,'PropName') or
PropValue = read(T,'PropName','PropParam')
or any combination of the previous syntaxes:
[PropValue1,PropValue2, ] = read(T,'PropName1','PropParam1','PropName2','PropParam2', )
where 'PropParam' is optional.
```

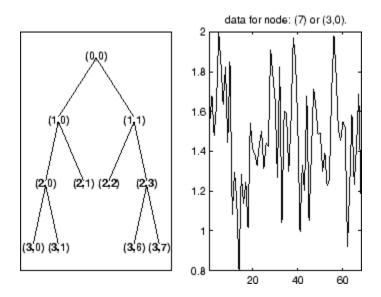

The valid choices for 'PropName' and 'PropParam' are listed in this table.

PropName	PropParam
'ent', 'ento' or 'sizes' (see wptree)	Without ' <i>PropParam</i> ' or with ' <i>PropParam</i> ' = Vector of node indices, PropValue contains the entropy (or optimal entropy, or size) of the tree nodes in ascending node index order.
'cfs'	With 'PropParam' = One terminal node index. cfs = read(T,'cfs',NODE) is equivalent to cfs = read(T,'data',NODE) and returns the coefficients of the terminal node NODE.

PropName	PropParam
'entName', 'entPar', 'wavName' (see wptree) or 'allcfs'	Without 'PropParam'.cfs = read(T, 'allcfs') is equivalent to cfs = read(T, 'data'). PropValue contains the desired information in ascending node index order of the tree nodes.
'wfilters' (see wfilters)	Without 'PropParam' or with 'PropParam' = 'd', 'r', 'l', 'h'.
'data'	Without 'PropParam' or with 'PropParam' = One terminal node index or 'PropParam' = Column vector of terminal node indices.In this last case, PropValue is a cell array. Without 'PropParam', PropValue contains the coefficients of the tree nodes in ascending node index order.

Examples

```
% Create a wavelet packet tree.
x = rand(1,512);
t = wpdec(x,3,'db3');
t = wpjoin(t,[4;5]);
plot(t);
% Click the node (3,0), (see the plot function).
1% Read values.
sAll = read(t, 'sizes');
sNod = read(t, 'sizes',[0,4,5]);
eAll = read(t, 'ent');
eNod = read(t, 'ent', [0,4,5]);
dAll = read(t, 'data');
dNod = read(t, 'data', [4;5]);
[lo_D,hi_D,lo_R,hi_R] = read(t,'wfilters');
[lo_D,lo_R,hi_D,hi_R] = read(t,'wfilters','l','wfilters','h');
[ent,ento,cfs4,cfs5] = read(t,'ent','ento','cfs',4,'cfs',5);
```

See Alsodisp | get | set | wptree | write

readtree

Read wavelet packet decomposition tree from figure

Syntax

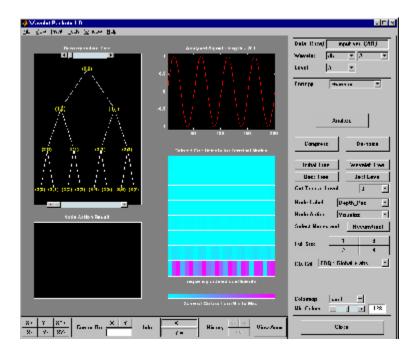

```
T = readtree(F)
```

Description

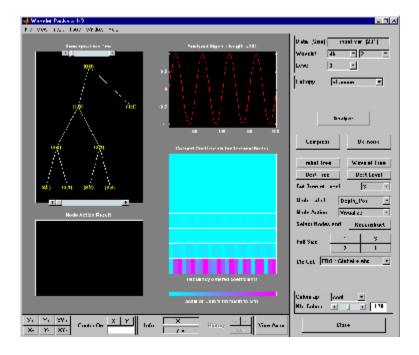

T = readtree(F) reads the wavelet packet decomposition tree from the figure whose handle is F.

Examples

```
% Create a wavelet packet tree.
x = sin(8*pi*[0:0.005:1]);
t = wpdec(x,3,'db2');
% Display the generated tree in a Wavelet Packet 1-D GUI window.
fig = drawtree(t);
```

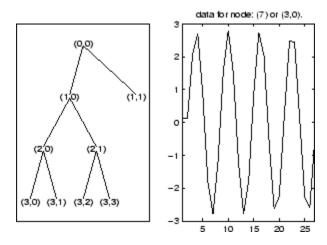

%-----% Use the GUI to split or merge Nodes.

t = readtree(fig);
plot(t)

% Click the node (3,0), (see the plot function).

drawtree

scal2frq

Scale to frequency

Syntax

```
F = scal2frq(A, 'wname', DELTA)
scal2frq(A, 'wname')
scal2frq(A, 'wname', 1)
```

Description

F = scal2frq(A, 'wname', DELTA) returns the pseudo-frequencies corresponding to the scales given by A and the wavelet function 'wname' (see wavefun for more information) and the sampling period DELTA.

```
scal2frq(A, 'wname') is equivalent to scal2frq(A, 'wname', 1).
```

There is only an approximate answer for the relationship between scale and frequency.

In wavelet analysis, the way to relate scale to frequency is to determine the center frequency of the wavelet, F_c , and use the following relationship.

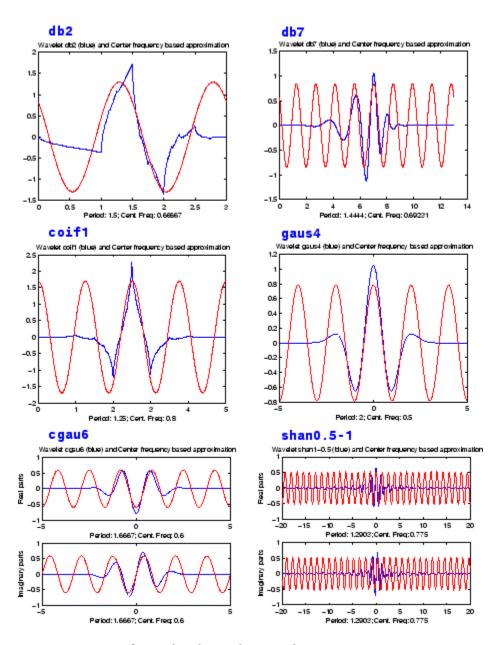

$$F_a = \frac{F_c}{a \cdot \Delta}$$

where

- a is a scale.
- Δ is the sampling period.
- F_c is the center frequency of a wavelet in Hz.
- F_a is the pseudo-frequency corresponding to the scale a, in Hz.

The idea is to associate with a given wavelet a purely periodic signal of frequency F_c . The frequency maximizing the Fourier transform of the wavelet modulus is F_c . centfrq computes the center frequency for a specified wavelet.

Some examples of the correspondence between the center frequency and the wavelet are shown in the following figure.

Center Frequencies for Real and Complex Wavelets

As you can see, the center frequency-based approximation captures the main wavelet oscillations. Therefore, the center frequency is a convenient and simple characterization of the dominant frequency of the wavelet.

Dilating the wavelet by a, changes the center frequency to F_c / a . If the underlying sampling period is Δ , the scale a corresponds to the frequency

$$F_a = \frac{F_c}{a \cdot \Delta}$$

scal2frq computes this correspondence.

Examples

Scales To Frequencies

Construct a vector of scales with 10 voices per octave over five octaves. Assume the data are sampled at 10 kHz.

```
voicesperoctave = 10;
numoctaves = 5;
a0 = 2^(1/voicesperoctave);
Fs = 1e4;
scales = ...
    a0.^(voicesperoctave:1/voicesperoctave:numoctaves*voicesperoctave);
```

Convert the scales to approximate frequencies in hertz for the Morlet wavelet.

```
Frq = scal2frq(scales, 'morl', 1/Fs);
```

Determine the corresponding periods. Construct a table with the scales, the corresponding frequencies, and periods. Display the smallest 20 scales along with their corresponding frequencies and periods.

```
Frq = Frq(:);
scales = scales(:);
T = [scales.*(1/Fs) Frq 1./Frq];
T = array2table(T,'VariableNames',{'Scale','Frequency','Period'});
T(1:20,:)
```

ans =

Plot CWT with Frequencies instead of Scales

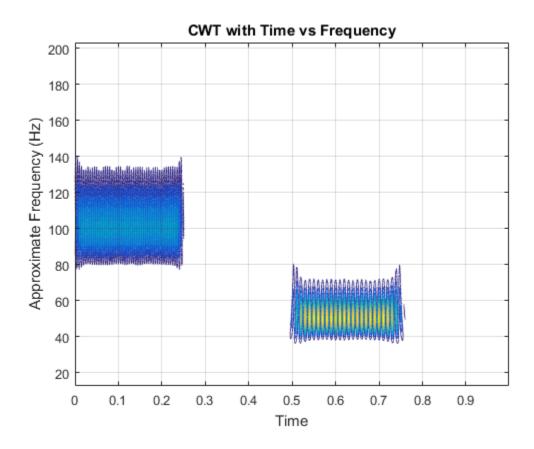

The example shows how to plot the CWT using approximate frequencies in Hz instead of scales. This creates a time-frequency plot instead of a time-scale plot.

Create a signal consisting of two sine waves with disjoint support in additive noise. Assume the signal is sampled at 1 kHz.

```
Fs = 1000;
t = 0:1/Fs:1-1/Fs;
x = 1.5*cos(2*pi*100*t).*(t<0.25)+1.5*cos(2*pi*50*t).*(t>0.5 & t<=0.75);
x = x+0.05*randn(size(t));
```

Obtain the CWT of the input signal with the Morlet wavelet. Set the number of voices per octave to 32. Create a scale vector to cover 6 octaves. The initial scale is $4\Delta t$ where Δt is the sampling interval.

```
numvoices = 32;
a0 = 2^(1/numvoices);
numoctaves = 6;
scales = a0.^(2*numvoices:1/numvoices:numoctaves*numvoices);
cfs = cwt(x,scales,'morl');
Convert the scales to approximate frequencies and plot the result.
pfreq = scal2frq(scales,'morl',1/Fs);
contour(t,pfreq,abs(cfs).^2);
axis tight;
grid on;
xlabel('Time');
ylabel('Approximate Frequency (Hz)');
title('CWT with Time vs Frequency');
```

centfrq

set

WPTREE field contents

Syntax

```
T = set(T, 'FieldName1', FieldValue1, 'FieldName2', FieldValue2, ...)
```

Description

T = set(T, 'FieldName1', FieldValue1, 'FieldName2', FieldValue2, ...) sets the content of the specified fields for the WPTREE object T.

For the fields that are objects or structures, you can set the subfield contents, giving the name of these subfields as 'FieldName' values.

The valid choices for 'FieldName' are

'dtree'	DTREE parent object
'wavInfo'	Structure (wavelet information)

The fields of the wavelet information structure, 'wavInfo', are also valid for 'FieldName':

'wavName'	Wavelet name
'Lo_D'	Low Decomposition filter
'Hi_D'	High Decomposition filter
'Lo_R'	Low Reconstruction filter
'Hi_R'	High Reconstruction filter

'entInfo'	Structure (entropy information)
-----------	---------------------------------

The fields of the entropy information structure, 'entInfo', are also valid for 'FieldName':

'entName'	Entropy name
'entPar'	Entropy parameter

Or fields of DTREE parent object:

'ntree'	NTREE parent object
'allNI'	All nodes information
'terNI'	Terminal nodes information

Or fields of NTREE parent object:

'wtbo'	WTBO parent object
'order'	Order of the tree
'depth'	Depth of the tree
'spsch'	Split scheme for nodes
'tn'	Array of terminal nodes of the tree

Or fields of WTBO parent object:

'wtboInfo'	Object information
'ud'	Userdata field

Caution The set function should only be used to set the field 'ud'.

shanwavf

Complex Shannon wavelet

Syntax

```
[PSI,X] = shanwavf(LB,UB,N,FB,FC)
```

Description

[PSI,X] = shanwavf(LB,UB,N,FB,FC) returns values of the complex Shannon wavelet. The complex Shannon wavelet is defined by a bandwidth parameter FB, a wavelet center frequency FC, and the expression

```
PSI(X) = (FB^0.5)*(sinc(FB*X).*exp(2*i*pi*FC*X))
```

on an N point regular grid in the interval [LB, UB].

FB and FC must be such that FC > 0 and FB > 0.

Output arguments are the wavelet function PSI computed on the grid X.

Examples

Complex Shannon Wavelet

Obtain and plot a complex Shannon wavelet. Set the bandwidth and center frequency parameters.

```
fb = 1; fc = 1.5;
```

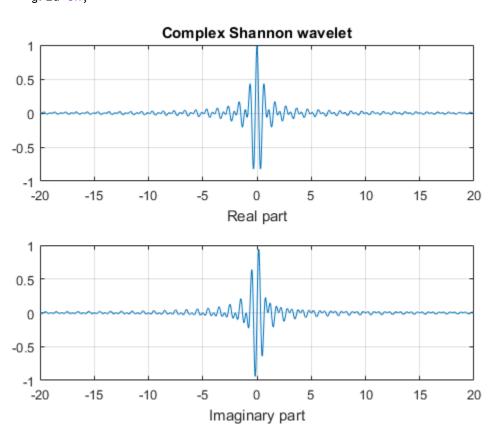

Set the effective support and number of sample points.

```
lb = -20;
ub = 20;
n = 1000;
```

Obtain the complex-valued Shannon wavelet and plot the real and imaginary parts.

```
[psi,x] = shanwavf(lb,ub,n,fb,fc);
```

```
subplot(211)
plot(x,real(psi))
title('Complex Shannon wavelet')
xlabel('Real part');
grid on;
subplot(212)
plot(x,imag(psi))
xlabel('Imaginary part')
grid on;
```

waveinfo

swt

Discrete stationary wavelet transform 1-D

Syntax

```
SWC = swt(X,N,'wname')
SWC = swt(X,N,Lo_D,Hi_D)
```

Description

swt performs a multilevel 1-D stationary wavelet decomposition using either a specific orthogonal wavelet ('wname', see wfilters for more information) or specific orthogonal wavelet decomposition filters.

SWC = swt(X,N,'wname') computes the stationary wavelet decomposition of the signal X at level N, using 'wname'.

N must be a strictly positive integer (see wmaxlev for more information) and length(X) must be a multiple of 2^N .

SWC = swt(X,N,Lo_D,Hi_D) computes the stationary wavelet decomposition as above, given these filters as input:

- · Lo D is the decomposition low-pass filter.
- · Hi_D is the decomposition high-pass filter.

Lo D and Hi D must be the same length.

The output matrix SWC contains the vectors of coefficients stored row-wise:

For $1 \le i \le N$, the output matrix SWC(i,:) contains the detail coefficients of level i and SWC(N+1,:) contains the approximation coefficients of level N.

[SWA,SWD] = swt() computes approximations, SWA, and details, SWD, stationary wavelet coefficients.

The vectors of coefficients are stored row-wise:

For $1 \le i \le N$, the output matrix SWA(i,:) contains the approximation coefficients of level i and the output matrix SWD(i,:) contains the detail coefficients of level i.

Note swt is defined using dwt with periodic extension.

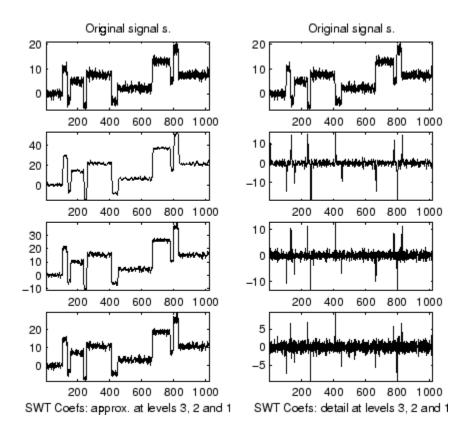

Examples

```
% Load original 1D signal.
load noisbloc; s = noisbloc;

% Perform SWT decomposition at level 3 of s using db1.
[swa,swd] = swt(s,3,'db1');

% Plots of SWT coefficients of approximations and details
% at levels 3 to 1.

% Using some plotting commands,
% the following figure is generated.
```

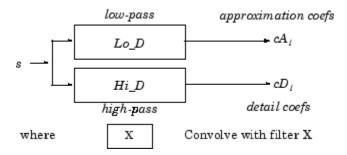

More About

Algorithms

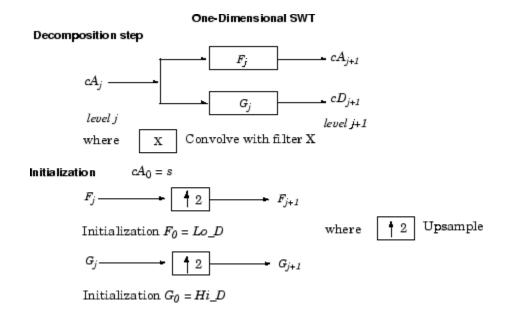

Given a signal s of length N, the first step of the SWT produces, starting from s, two sets of coefficients: approximation coefficients cA_I and detail coefficients cD_I . These vectors are obtained by convolving s with the low-pass filter Lo_D for approximation, and with the high-pass filter Hi_D for detail.

More precisely, the first step is

Note cA_1 and cD_1 are of length N instead of N/2 as in the DWT case.

The next step splits the approximation coefficients cA_I in two parts using the same scheme, but with modified filters obtained by upsampling the filters used for the previous step and replacing s by cA_I . Then, the SWT produces cA_2 and cD_2 . More generally,

swt2

Discrete stationary wavelet transform 2-D

Syntax

```
SWC = swt2(X,N,'wname')
[A,H,V,D] = swt2(X,N,'wname')
SWC = swt2(X,N,Lo_D,Hi_D)
[A,H,V,D] = swt2(X,N,Lo_D,Hi_D)
```

Description

swt2 performs a multilevel 2-D stationary wavelet decomposition using either a specific orthogonal wavelet ('wname' — see wfilters for more information) or specific orthogonal wavelet decomposition filters.

SWC = swt2(X,N,'wname') or [A,H,V,D] = swt2(X,N,'wname') compute the stationary wavelet decomposition of the matrix X at level N, using 'wname'.

N must be a strictly positive integer (see wmaxlev for more information), and 2^N must divide size(X,1) and size(X,2).

Outputs [A,H,V,D] are 3-D arrays, which contain the coefficients:

- For $1 \le i \le N$, the output matrix A(:,:,i) contains the coefficients of approximation of level i.
- The output matrices H(:,:,i), V(:,:,i) and D(:,:,i) contain the coefficients of details of level i (horizontal, vertical, and diagonal):

```
SWC = [H(:,:,1:N) ; V(:,:,1:N) ; D(:,:,1:N) ; A(:,:,N)]
```

SWC = $swt2(X,N,Lo_D,Hi_D)$ or [A,H,V,D] = $swt2(X,N,Lo_D,Hi_D)$, computes the stationary wavelet decomposition as in the previous syntax, given these filters as input:

• Lo_D is the decomposition low-pass filter.

· Hi D is the decomposition high-pass filter.

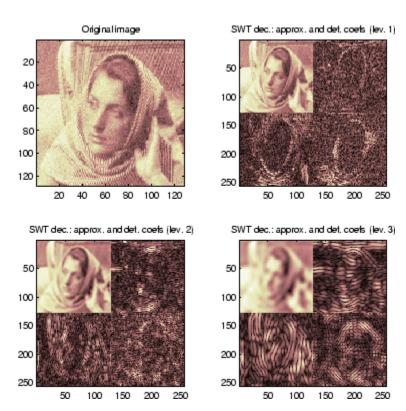

Lo_D and Hi_D must be the same length.

Note swt2 is defined using dwt with periodic extension.

Examples

```
% Load original image.
load nbarb1;
% Image coding.
nbcol = size(map, 1);
cod X = wcodemat(X, nbcol);
% Visualize the original image.
subplot (221)
image(cod X)
title('Original image');
colormap(map)
% Perform SWT decomposition
% of X at level 3 using sym4.
[ca, chd, cvd, cdd] = swt2(X,3, 'sym4');
% Visualize the decomposition.
for k = 1:3
    % Images coding for level k.
    cod ca = wcodemat(ca(:,:,k),nbcol);
    cod chd = wcodemat(chd(:,:,k),nbcol);
    cod cvd = wcodemat(cvd(:,:,k),nbcol);
    cod cdd = wcodemat(cdd(:,:,k),nbcol);
    decl = [cod ca,cod chd;cod cvd,cod cdd];
    % Visualize the coefficients of the decomposition
    % at level k.
    subplot(2,2,k+1)
    image(decl)
    title(['SWT dec.: approx. ', ...
   'and det. coefs (lev. ',num2str(k),')']);
```

```
colormap(map)
end
% Editing some graphical properties,
% the following figure is generated.
```

More About

Tips

When X represents an indexed image, X is an m-by-n matrix and the output arrays SWC or cA,cH,cV, and cD are m-by-n-by-p arrays.

When X represents a truecolor image, it becomes an M-by-n-by-3 array. This array is an M-by-n-by-3 array, where each M-by-n matrix represents a red, green, or blue color plane

concatenated along the third dimension. The output arrays SWC or cA,cH,cV, and cD are m-by-n-by-9 arrays.

For more information on image formats, see the image and imfinfo reference pages.

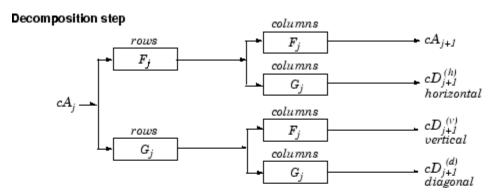

Algorithms

For images, an algorithm similar to the one-dimensional case is possible for twodimensional wavelets and scaling functions obtained from one-dimensional ones by tensor product.

This kind of two-dimensional SWT leads to a decomposition of approximation coefficients at level j in four components: the approximation at level j+1, and the details in three orientations (horizontal, vertical, and diagonal).

The following chart describes the basic decomposition step for images:

Two-Dimensional SWT

where

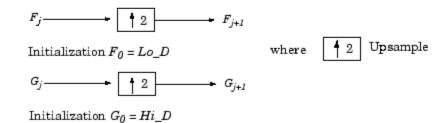

rows

X Convolve with filter X the rows of the entry

columns

X Convolve with filter X the columns of the entry

Initialization $cA_0 = s$ for the decomposition initialization

Note $size(cA_j) = size(cD_j^{(h)}) = size(cD_j^{(v)}) = size(cD_j^{(d)}) = s$ where s = size of the analyzed image

symaux

Symlet wavelet filter computation

Syntax

```
W = SYMAUX(N,SUMW)
W = SYMAUX(N)
W = SYMAUX(N,1)
W = SYMAUX(N,0)
W = SYMAUX(N,1)
```

Description

Symlets are the Äúleast asymmetricÄù Daubechies wavelets.

```
W = SYMAUX(N, SUMW) is the order N Symlet scaling filter such that SUM(W) = SUMW. Possible values for N are 1, 2, 3, ...
```

Note Instability may occur when N is too large.

```
W = SYMAUX(N) is equivalent to W = SYMAUX(N,1).

W = SYMAUX(N,0) is equivalent to W = SYMAUX(N,1).
```

Examples

```
% Generate wdb4 the order 4 Daubechies scaling filter.
wdb4 = dbaux(4)
wdb4 =

Columns 1 through 7

symaux | waveinfo

thselect

Threshold selection for de-noising

Syntax

THR = thselect(X, TPTR)

Description

thselect is a one-dimensional de-noising oriented function.

THR = thselect(X,TPTR) returns threshold X-adapted value using selection rule defined by string TPTR.

Available selection rules are

- TPTR = 'rigrsure', adaptive threshold selection using principle of Stein's Unbiased Risk Estimate.
- TPTR = 'heursure', heuristic variant of the first option.
- TPTR = 'sqtwolog', threshold is sqrt(2*log(length(X))).
- TPTR = 'minimaxi', minimax thresholding.

Threshold selection rules are based on the underlying model y = f(t) + e where e is a white noise N(0,1). Dealing with unscaled or nonwhite noise can be handled using rescaling output threshold THR (see SCAL parameter in wden for more information).

Available options are

- tptr = 'rigrsure' uses for the soft threshold estimator, a threshold selection rule based on SteinÄôs Unbiased Estimate of Risk (quadratic loss function). One gets an estimate of the risk for a particular threshold value (t). Minimizing the risks in (t) gives a selection of the threshold value.
- tptr = 'sqtwolog' uses a fixed-form threshold yielding minimax performance multiplied by a small factor proportional to log(length(X)).
- tptr = 'heursure' is a mixture of the two previous options. As a result, if the signal to noise ratio is very small, the SURE estimate is very noisy. If such a situation is detected, the fixed form threshold is used.

• tptr = 'minimaxi' uses a fixed threshold chosen to yield minimax performance for mean square error against an ideal procedure. The minimax principle is used in statistics in order to design estimators. Since the de-noised signal can be assimilated to the estimator of the unknown regression function, the minimax estimator is the one that realizes the minimum of the maximum mean square error obtained for the worst function in a given set.

Examples

```
% The current extension mode is zero-padding (see dwtmode).
% Generate Gaussian white noise.
x = randn(1,1000);

% Find threshold for each selection rule.
% Adaptive threshold using SURE.
thr = thselect(x,'rigrsure')
% Fixed form threshold.
thr = thselect(x,'sqtwolog')
% Heuristic variant of the first option.
thr = thselect(x,'heursure')
% Minimax threshold.
thr = thselect(x,'minimaxi')
```

tnodes

Determine terminal nodes

Syntax

```
N = tnodes(T)
N = tnodes(T, 'deppos')
[N,K] = tnodes(T)
[N,K] = tnodes(T, 'deppos'), M = N(K)
```

Description

tnodes is a tree-management utility.

N = tnodes(T) returns the indices of terminal nodes of the tree T. N is a column vector.

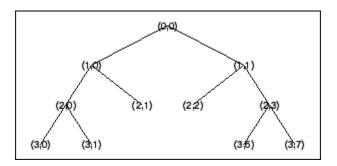

The nodes are numbered from left to right and from top to bottom. The root index is 0.

N = tnodes(T, 'deppos') returns a matrix N, which contains the depths and positions of terminal nodes.

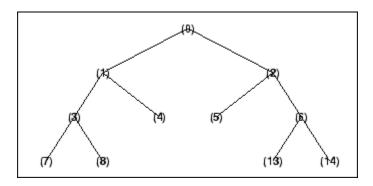

N(i,1) is the depth of the i-th terminal node. N(i,2) is the position of the i-th terminal node.

For [N,K] = tnodes(T) or [N,K] = tnodes(T, 'deppos'), M = N(K) are the indices reordered as in tree T, from left to right.

```
% Create initial tree.
ord = 2;
t = ntree(ord,3); % Binary tree of depth 3.
t = nodejoin(t,5);
t = nodejoin(t,4);
plot(t)

upcoef

Direct reconstruction from 1-D wavelet coefficients

Syntax

```
Y = upcoef(0,X,'wname',N)
Y = upcoef(0,X,'wname',N,L)
Y = upcoef(0,X,Lo_R,Hi_R,N)
Y = upcoef(0,X,Lo_R,Hi_R,N,L)
Y = upcoef(0,X,'wname'')
Y = upcoef(0,X,'wname'',1)
Y = upcoef(0,X,Lo_R,Hi_R)
Y = upcoef(0,X,Lo_R,Hi_R,1)
```

Description

upcoef is a one-dimensional wavelet analysis function.

```
Y = upcoef(0,X,'wname',N) computes the N-step reconstructed coefficients of vector X.
```

'wname' is a string containing the wavelet name. See wfilters for more information.

N must be a strictly positive integer.

If 0 = 'a', approximation coefficients are reconstructed.

If 0 = 'd', detail coefficients are reconstructed.

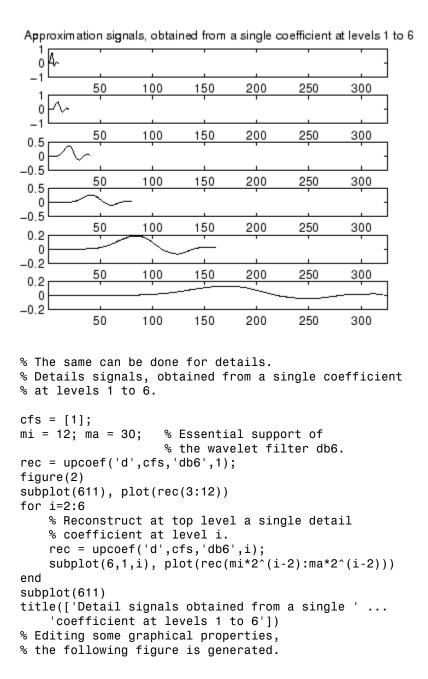

Y = upcoef(0, X, 'wname', N, L) computes the N-step reconstructed coefficients of vector X and takes the length-L central portion of the result.

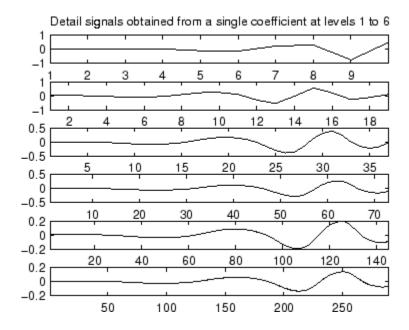

Instead of giving the wavelet name, you can give the filters.

For $Y = \text{upcoef}(0, X, \text{Lo}_R, \text{Hi}_R, N)$ or $Y = \text{upcoef}(0, X, \text{Lo}_R, \text{Hi}_R, N, L)$, Lo_R is the reconstruction low-pass filter and Hi_R is the reconstruction high-pass filter.

```
Y = upcoef(0,X,'wname'') is equivalent to Y = upcoef(0,X,'wname'',1).
Y = upcoef(0,X,Lo R,Hi R) is equivalent to Y = upcoef(0,X,Lo R,Hi R,1).
```

```
% The current extension mode is zero-padding (see dwtmode).
% Approximation signals, obtained from a single coefficient
% at levels 1 to 6.
cfs = [1]; % Decomposition reduced a single coefficient.
essup = 10; % Essential support of the scaling filter db6.

upcoef2

Direct reconstruction from 2-D wavelet coefficients

Syntax

```
Y = upcoef2(0,X,'wname',N,S)
Y = upcoef2(0,X,Lo_R,Hi_R,N,S)
Y = upcoef2(0,X,'wname',N)
Y = upcoef2(0,X,Lo_R,Hi_R,N)
Y = upcoef2(0,X,'wname')
Y = upcoef2(0,X,'wname',1)
Y = upcoef2(0,X,Lo_R,Hi_R)
Y = upcoef2(0,X,Lo_R,Hi_R,1)
```

Description

upcoef2 is a two-dimensional wavelet analysis function.

Y = upcoef2(0,X,'wname',N,S) computes the N-step reconstructed coefficients of matrix X and takes the central part of size S. 'wname' is a string containing the name of the wavelet. See Wfilters for more information.

If 0 = 'a', approximation coefficients are reconstructed; otherwise if 0 = 'h' ('v') or 'd', respectively), horizontal (vertical or diagonal, respectively) detail coefficients are reconstructed. N must be a strictly positive integer.

Instead of giving the wavelet name, you can give the filters.

For Y = upcoef2(0,X,Lo_R,Hi_R,N,S) is the reconstruction low-pass filter and Hi_R is the reconstruction high-pass filter.

 $Y = upcoef2(0,X, 'wname',N) \text{ or } Y = upcoef2(0,X,Lo_R,Hi_R,N) \text{ returns the computed result without any truncation.}$

```
Y = upcoef2(0,X,'wname') is equivalent to Y = upcoef2(0,X,'wname',1).
Y = upcoef2(0,X,Lo_R,Hi_R) is equivalent to
Y = upcoef2(0,X,Lo_R,Hi_R,1).
```

Examples

```
% The current extension mode is zero-padding (see dwtmode).
% Load original image.
load woman;
% X contains the loaded image.
% Perform decomposition at level 2
% of X using db4.
[c,s] = wavedec2(X,2,'db4');
% Reconstruct approximation and details
% at level 1, from coefficients.
% This can be done using wrcoef2, or
% equivalently using:
% Step 1: Extract coefficients from the
% decomposition structure [c,s].
% Step 2: Reconstruct using upcoef2.
siz = s(size(s,1),:);
ca1 = appcoef2(c,s,'db4',1);
a1 = upcoef2('a',ca1,'db4',1,siz);
chd1 = detcoef2('h',c,s,1);
hd1 = upcoef2('h',chd1,'db4',1,siz);
cvd1 = detcoef2('v',c,s,1);
vd1 = upcoef2('v',cvd1,'db4',1,siz);
cdd1 = detcoef2('d',c,s,1);
dd1 = upcoef2('d',cdd1,'db4',1,siz);
```

upwlev

Single-level reconstruction of 1-D wavelet decomposition

Syntax

```
[NC,NL,cA] = upwlev(C,L,'wname')
```

Description

upwlev is a one-dimensional wavelet analysis function.

[NC,NL,cA] = upwlev(C,L,'wname') performs the single-level reconstruction of the wavelet decomposition structure [C,L] giving the new one [NC,NL], and extracts the last approximation coefficients vector cA.

[C,L] is a decomposition at level n = length(L) - 2, so [NC,NL] is the same decomposition at level n-1 and cA is the approximation coefficients vector at level n.

'wname' is a string containing the wavelet name, C is the original wavelet decomposition vector, and L the corresponding bookkeeping vector (for detailed storage information, see wavedec).

Instead of giving the wavelet name, you can give the filters.

For [NC,NL,cA] = upwlev(C,L,Lo_R,Hi_R), Lo_R is the reconstruction low-pass filter and Hi_R is the reconstruction high-pass filter.

```
% The current extension mode is zero-padding (see dwtmode).

wave2lp

Laurent polynomials associated with wavelet

Syntax

```
[Hs,Gs,Ha,Ga] = wave2lp(W)
```

Description

[Hs,Gs,Ha,Ga] = wave2lp(W) returns the four Laurent polynomials associated with the wavelet W (see liftwave).

The pairs (Hs,Gs) and (Ha,Ga) are the synthesis and the analysis pair respectively.

The H-polynomials (G-polynomials) are low-pass (high-pass) polynomials.

For an orthogonal wavelet, Hs = Ha and Gs = Ga.

```
% Get Laurent polynomials associated to the "lazy" wavelet. [Hs,Gs,Ha,Ga] = wave2lp('lazy')

Hs(z) = 1

Gs(z) = z^{(-1)}

Ha(z) = 1

Ga(z) = z^{(-1)}

% Get Laurent polynomials associated to the db1 wavelet. [Hs,Gs,Ha,Ga] = wave2lp('db1')

Hs(z) = + 0.7071 + 0.7071*z^{(-1)}
```

```
\label{eq:hamiltonian} \begin{split} &\text{Ha}(z) = +\ 0.7071 +\ 0.7071*z^{(-1)} \\ &\text{Ga}(z) = -\ 0.7071 +\ 0.7071*z^{(-1)} \\ &\text{\% Get Laurent polynomials associated to the bior1.3 wavelet.} \\ &[\text{Hs,Gs,Ha,Ga}] = \text{wave2lp('bior1.3')} \\ &\text{Hs}(z) = +\ 0.7071 +\ 0.7071*z^{(-1)} \\ &\text{Gs}(z) = \dots \\ &+\ 0.08839*z^{(+2)} +\ 0.08839*z^{(+1)} -\ 0.7071 +\ 0.7071*z^{(-1)} -\ 0.08839*z^{(-2)} &\dots \\ &-\ 0.08839*z^{(-3)} \\ &\text{Ga}(z) = -\ 0.7071 +\ 0.7071*z^{(-1)} \end{split}
```

wavedec

Multilevel 1-D wavelet decomposition

Syntax

```
[C,L] = wavedec(X,N,'wname')
[C,L] = wavedec(X,N,Lo_D,Hi_D)
```

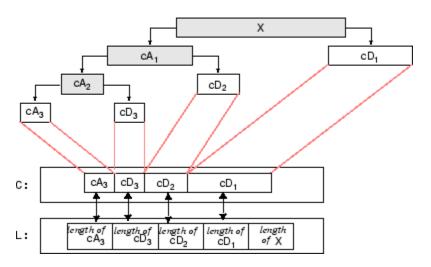

Description

wavedec performs a multilevel one-dimensional wavelet analysis using either a specific wavelet ('wname') or a specific wavelet decomposition filters (Lo_D and Hi_D, see wfilters).

Note wavedec supports only Type 1 (orthogonal) or Type 2 (biorthogonal) wavelets.

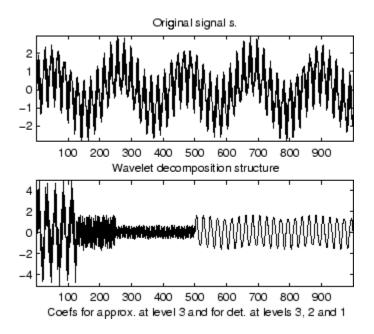

[C,L] = wavedec(X,N,'wname') returns the wavelet decomposition of the signal X at level N, using 'wname'. N must be a strictly positive integer (see wmaxlev for more information). The output decomposition structure contains the wavelet decomposition vector C and the bookkeeping vector L. The structure is organized as in this level-3 decomposition example.

Decomposition:

[C,L] = wavedec(X,N,Lo_D,Hi_D) returns the decomposition structure as above, given the low- and high-pass decomposition filters you specify.

```
% The current extension mode is zero-padding (see dwtmode).
% Load original one-dimensional signal.
load sumsin; s = sumsin;
% Perform decomposition at level 3 of s using db1.
[c,l] = wavedec(s,3,'db1');
% Using some plotting commands,
% the following figure is generated.
```

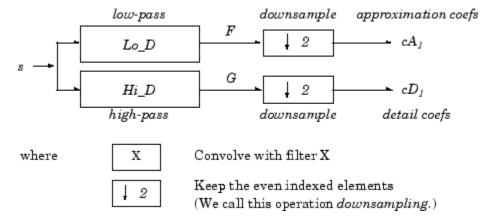

More About

Algorithms

Given a signal s of length N, the DWT consists of $\log_2 N$ stages at most. The first step produces, starting from s, two sets of coefficients: approximation coefficients CA_I , and detail coefficients CD_I . These vectors are obtained by convolving s with the low-pass filter Lo_D for approximation, and with the high-pass filter Hi_D for detail, followed by dyadic decimation (downsampling).

More precisely, the first step is

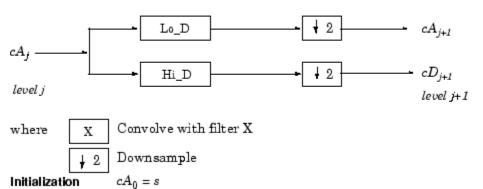

The length of each filter is equal to 2N. If n = length(s), the signals F and G are of length n + 2N - 1 and the coefficients cA_1 and cD_1 are of length

floor
$$\left(\frac{n-1}{2}\right) + N$$

The next step splits the approximation coefficients cA_1 in two parts using the same scheme, replacing s by cA_1 , and producing cA_2 and cD_2 , and so on

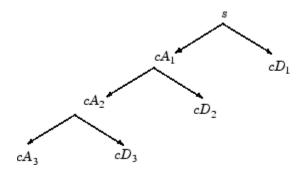

One-Dimensional DWT

Decomposition step

The wavelet decomposition of the signal s analyzed at level j has the following structure: $[cA_j, cD_j, ..., cD_I]$.

This structure contains, for J = 3, the terminal nodes of the following tree:

Syntax

```
[C,S] = wavedec2(X,N,'wname')
[C,S] = wavedec2(X,N,Lo_D,Hi_D)
```

Description

wavedec2 is a two-dimensional wavelet analysis function.

[C,S] = wavedec2(X,N,'wname') returns the wavelet decomposition of the matrix
X at level N, using the wavelet named in string 'wname' (see wfilters for more
information).

Outputs are the decomposition vector C and the corresponding bookkeeping matrix S.

N must be a strictly positive integer (see wmaxlev for more information).

Instead of giving the wavelet name, you can give the filters.

For [C,S] = wavedec2(X,N,Lo_D,Hi_D), Lo_D is the decomposition low-pass filter and Hi D is the decomposition high-pass filter.

Vector C is organized as

```
C = [A(N) | H(N) | V(N) | D(N) | ... 
H(N-1) | V(N-1) | D(N-1) | ... | H(1) | V(1) | D(1) ].
```

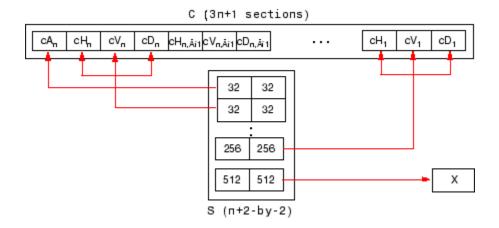

where A, H, V, D, are row vectors such that

- A = approximation coefficients
- H = horizontal detail coefficients
- V = vertical detail coefficients
- D = diagonal detail coefficients

• Each vector is the vector column-wise storage of a matrix.

Matrix S is such that

- S(1,:) = size of approximation coefficients(N).
- S(i,:) = size of detail coefficients(N-i+2) for i = 2, ...N+1 and S(N+2,:) = size(X).

```
sizec =
    1 65536
    val_s = s

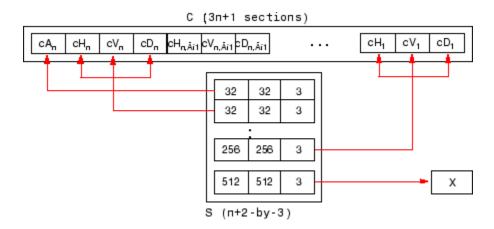

val_s =
    64 64
    64 64
    128 128
    256 256
```

More About

Tips

When X represents an indexed image, X, as well as the output arrays cA,cH,cV, and cD are M-by-n matrices. When X represents a truecolor image, it is an M-by-n-by-3 array, where each M-by-n matrix represents a red, green, or blue color plane concatenated along the third dimension. The size of vector C and the size of matrix S depend on the type of analyzed image.

For a truecolor image, the decomposition vector **C** and the corresponding bookkeeping matrix **S** can be represented as follows.

For more information on image formats, see the image and imfinfo reference pages.

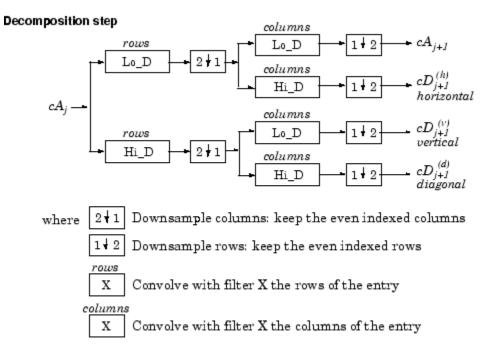

Algorithms

For images, an algorithm similar to the one-dimensional case is possible for twodimensional wavelets and scaling functions obtained from one-dimensional ones by tensor product.

This kind of two-dimensional DWT leads to a decomposition of approximation coefficients at level j in four components: the approximation at level j+1, and the details in three orientations (horizontal, vertical, and diagonal).

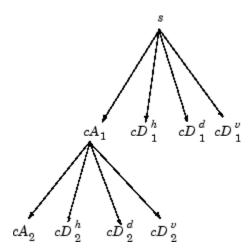

The following chart describes the basic decomposition step for images:

Two-Dimensional DWT

Initialization $cA_0 = s$ for the decomposition initialization

So, for J=2, the two-dimensional wavelet tree has the form

wavedec3

Multilevel 3-D wavelet decomposition

Syntax

```
WDEC = wavedec3(X,N,'wname')
WDEC = wavedec3(X,N,'wname','mode','ExtM')
WDEC = wavedec3(X,N,{LoD,HiD,LoR,HiR})
```

Description

wavedec3 is a three-dimensional wavelet analysis function.

WDEC = wavedec3(X,N,'wname') returns the wavelet decomposition of the 3-D array X at level N, using the wavelet named in string 'wname' or the particular wavelet filters you specify. It uses the default extension mode 'sym'. See dwtmode. N must be a positive integer.

```
WDEC = wavedec3(X,N,'wname','mode','ExtM') uses the specified DWT extension mode.
```

WDEC = wavedec3(X,N,{LoD,HiD,LoR,HiR}) uses the decomposition and reconstruction filters you specify in a cell array.

WDEC is the output decomposition structure, with the following fields:

sizeINI	Size of the three-dimensional array X
level	Level of the decomposition
mode	Name of the wavelet transform extension mode
filters	Structure with 4 fields, LoD, HiD, LoR, HiR, which contain the filters used for the DWT.
dec	N x 1 cell array containing the coefficients of the decomposition. N is equal to $7*WDEC.level+1$.

sizes	operations are applied from left to right. For example, 'LHH' means that the lowpass (scaling) filter with downsampling is applied to the rows of X, followed by the highpass (wavelet) filter with downsampling applied to the columns of X. Finally, the highpass filter with downsampling is applied to the 3rd dimension of X. Successive sizes of the decomposition components
	At each level, the wavelet coefficients in dec{k +2},,dec{k+8} are in the following order: 'HLL','LHL','HHL','HLH','HLH','HHH'. The strings give the order in which the separable filtering
	For example, if WDEC.level=3, dec{2},,dec{8} contain the wavelet coefficients for level 3 (k=0), dec{9},,dec{15} contain the wavelet coefficients for level 2 (k=7), and dec{16},,dec{22} contain the wavelet coefficients for level 1 (k=7* (WDEC.level-1)).
	$dec\{k+2\},\ldots,dec\{k+8\}$ with $k=0,7,14,\ldots,7^*$ (WDEC.level-1) contain the 3-D wavelet coefficients for the multiresolution starting with the coarsest level when $k=0$.
	dec{1} contains the lowpass component (approximation) at the level of the decomposition. The approximation is equivalent to the filtering operations 'LLL'.

Examples

3-D Wavelet Transform

Find the 3-D DWT of a volume.

Construct 8-by-8-by-8 matrix. Obtain the 3-D discrete wavelet transform at level 1 using the Haar wavelet and the default whole-point symmetric extension mode.

```
% Matrix of integers 1:64
M = magic(8);
% Make data 3-D
```

```
X = repmat(M,[1 1 8]);
% Decompose X at level 1 using db1.
wd1 = wavedec3(X,1,'db1');
```

3-D Wavelet Transform Using Specified Decomposition and Reconstruction Filters

Specify the decomposition and reconstruction filters as a cell array.

Construct 8-by-8-by-8 matrix. Obtain the 3-D discrete wavelet transform down to level 2 using the Daubechies extremal phase wavelet with two vanishing moments. Input the decomposition and reconstruction filters as a cell array. Use the periodic extension mode.

```
% Matrix of integers 1:64
M = magic(8);
% Make data 3-D
X = repmat(M,[1 1 8]);
[LoD,HiD,LoR,HiR] = wfilters('db2');
wd2 = wavedec3(X,2,{LoD,HiD,LoR,HiR},'mode','per');
```

Coefficient Order in 3-D Wavelet Transform

Compare the output of wavedec3 and dwt3 to illustrate the ordering of the 3-D wavelet coefficients described in the dec field description.

```
X = reshape(1:512,8,8,8);
dwtOut = dwt3(X,'db1','mode','per');
wdec = wavedec3(X,1,'db1','mode','per');
max(abs((wdec.dec{4}(:)-dwtOut.dec{2,2,1}(:))))
max(abs((wdec.dec{5}(:)-dwtOut.dec{1,1,2}(:))))
```

wavedemo

Wavelet Toolbox software examples

Syntax

Description

 $\mbox{\tt wavedemo}$ opens a GUI that allows you to choose between several Wavelet Toolbox examples.

wavefun

Wavelet and scaling functions

Syntax

```
[PHI,PSI,XVAL] = wavefun('wname',ITER)
[PHI1,PSI1,PHI2,PSI2,XVAL] = wavefun('wname',ITER)
[PHI,PSI,XVAL] = wavefun('wname',ITER)
[PSI,XVAL] = wavefun('wname',ITER)
[...] = wavefun(wname,A,B)
[...] = wavefun('wname',max(A,B))
[...] = wavefun('wname',0)
[...] = wavefun('wname',8,0)
[...] = wavefun('wname',8,0)
[...] = wavefun('wname',8,0)
```

Description

The function wavefun returns approximations of the wavelet function 'wname' and the associated scaling function, if it exists. The positive integer ITER determines the number of iterations computed; thus, the refinement of the approximations.

For an orthogonal wavelet:

[PHI, PSI, XVAL] = wavefun('wname', ITER) returns the scaling and wavelet functions on the points grid XVAL.

For a biorthogonal wavelet:

[PHI1,PSI1,PHI2,PSI2,XVAL] = wavefun('wname',ITER) returns the scaling and wavelet functions both for decomposition (PHI1,PSI1) and for reconstruction (PHI2,PSI2).

For a Meyer wavelet:

```
[PHI,PSI,XVAL] = wavefun('wname',ITER)
```

For a wavelet without scaling function (e.g., Morlet, Mexican Hat, Gaussian derivatives wavelets or complex wavelets):

```
[PSI,XVAL] = wavefun('wname',ITER)
[...] = wavefun(wname,A,B), where A and B are positive integers, is equivalent to
[...] = wavefun('wname',max(A,B)), and draws plots.

When A is set equal to the special value 0,

• [...] = wavefun('wname',0) is equivalent to

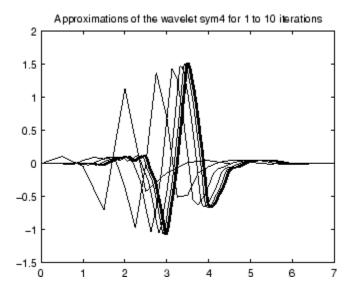

• [...] = wavefun('wname',8,0).

• [...] = wavefun('wname',8).
```

The output arguments are optional.

Examples

On the following graph, 10 piecewise linear approximations of the sym4 wavelet obtained after each iteration of the cascade algorithm are shown.

More About

Algorithms

For compactly supported wavelets defined by filters, in general no closed form analytic formula exists.

The algorithm used is the cascade algorithm. It uses the single-level inverse wavelet transform repeatedly.

Let us begin with the scaling function ϕ .

Since ϕ is also equal to $\phi_{0,0}$, this function is characterized by the following coefficients in the orthogonal framework:

- $\langle \phi, \phi_{\theta,n} \rangle = 1$ only if n = 0 and equal to 0 otherwise
- $\langle \phi, \psi_{-j,k} \rangle = 0$ for positive j, and all k.

This expansion can be viewed as a wavelet decomposition structure. Detail coefficients are all zeros and approximation coefficients are all zeros except one equal to 1.

Then we use the reconstruction algorithm to approximate the function ϕ over a dyadic grid, according to the following result:

For any dyadic rational of the form $x = n2^{-j}$ in which the function is continuous and where j is sufficiently large, we have pointwise convergence and

$$|\phi(x) - 2^{\frac{j}{2}} \langle \phi, \phi_{-j, n 2^{j-J}} \rangle| \le C. 2^{-j\alpha}$$

where C is a constant, and α is a positive constant depending on the wavelet regularity.

Then using a good approximation of ϕ on dyadic rationals, we can use piecewise constant or piecewise linear interpolations η on dyadic intervals, for which uniform convergence occurs with similar exponential rate:

$$\|\phi - \eta\|_{\infty} \le C \cdot 2^{-j\alpha}$$

So using a J-step reconstruction scheme, we obtain an approximation that converges exponentially towards ϕ when J goes to infinity.

Approximations are computed over a grid of dyadic rationals covering the support of the function to be approximated.

Since a scaled version of the wavelet function ψ can also be expanded on the $(\phi_{-1,n})_n$, the same scheme can be used, after a single-level reconstruction starting with the appropriate wavelet decomposition structure. Approximation coefficients are all zeros and detail coefficients are all zeros except one equal to 1.

For biorthogonal wavelets, the same ideas can be applied on each of the two multiresolution schemes in duality.

Note This algorithm may diverge if the function to be approximated is not continuous on dyadic rationals.

wavefun2

Wavelet and scaling functions 2-D

Syntax

```
[PHI,PSI,XVAL] = wavefun('wname',ITER)
[S,W1,W2,W3,XYVAL] = wavefun2('wname',ITER,'plot')
[S,W1,W2,W3,XYVAL] = wavefun2(wname,A,B)
[S,W1,W2,W3,XYVAL] = wavefun2('wname',max(A,B))
[S,W1,W2,W3,XYVAL] = wavefun2('wname',0)
[S,W1,W2,W3,XYVAL] = wavefun2('wname',4,0)
[S,W1,W2,W3,XYVAL] = wavefun2('wname')
[S,W1,W2,W3,XYVAL] = wavefun2('wname',4)
```

Description

For an orthogonal wavelet 'wname', wavefun2 returns the scaling function and the three wavelet functions resulting from the tensor products of the one-dimensional scaling and wavelet functions.

If [PHI, PSI, XVAL] = wavefun('wname', ITER), the scaling function S is the tensor product of PHI and PSI.

The wavelet functions W1, W2, and W3 are the tensor products (PHI,PSI), (PSI,PHI), and (PSI,PSI), respectively.

The two-dimensional variable XYVAL is a 2^{ITER} x 2^{ITER} points grid obtained from the tensor product (XVAL,XVAL).

The positive integer ITER determines the number of iterations computed and thus, the refinement of the approximations.

[S,W1,W2,W3,XYVAL] = wavefun2('wname',ITER,'plot') computes and also plots the functions.

[S,W1,W2,W3,XYVAL] = wavefun2(wname,A,B), where A and B are positive integers, is equivalent to

[S,W1,W2,W3,XYVAL] = wavefun2('wname', max(A,B)). The resulting functions are plotted.

When A is set equal to the special value 0,

```
    [S,W1,W2,W3,XYVAL] = wavefun2('wname',0) is equivalent to [S,W1,W2,W3,XYVAL] = wavefun2('wname',4,0).
    [S,W1,W2,W3,XYVAL] = wavefun2('wname') is equivalent to [S,W1,W2,W3,XYVAL] = wavefun2('wname',4).
```

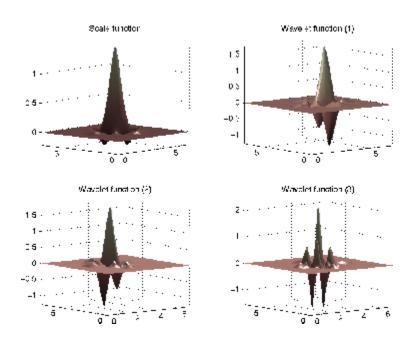

The output arguments are optional.

Note The wavefun2 function can only be used with an orthogonal wavelet.

Examples

On the following graph, a linear approximation of the **sym4** wavelet obtained using the cascade algorithm is shown.

```
% Set number of iterations and wavelet name.
iter = 4;
wav = 'sym4';
% Compute approximations of the wavelet and scale functions using
% the cascade algorithm and plot.
[s,w1,w2,w3,xyval] = wavefun2(wav,iter,0);
```

waveinfo

Wavelets information

Syntax

waveinfo('wname')

Description

waveinfo provides information on all wavelets within the toolbox.

waveinfo('wname') provides information on the wavelet family whose short name is specified by the string 'wname'. Available family short names are listed in the table below.

Wavelet Family Short Name	Wavelet Family Name
'haar'	Haar wavelet
'db'	Daubechies wavelets
'sym'	Symlets
'coif'	Coiflets
'bior'	Biorthogonal wavelets
'fk'	Fejer-Korovkin filters
'rbio'	Reverse biorthogonal wavelets
'meyr'	Meyer wavelet
'dmey'	Discrete approximation of Meyer wavelet
'gaus'	Gaussian wavelets
'mexh'	Mexican hat wavelet
'morl'	Morlet wavelet
'cgau'	Complex Gaussian wavelets

Wavelet Family Short Name	Wavelet Family Name
'shan'	Shannon wavelets
'fbsp'	Frequency B-Spline wavelets
'cmor'	Complex Morlet wavelets

The family short names can also be user-defined ones (see wavemngr for more information).

waveinfo('wsys') provides information on wavelet packets.

Examples

```
waveinfo('db')
```

Wavelet Toolbox GUI tools

Syntax

Description

wavemenu opens a menu for accessing the various graphical tools provided in the Wavelet Toolbox software.

Examples

wavemenu

wavemngr

Wavelet manager

Syntax

```
wavemngr('add',FN,FSN,WT,NUMS,FILE)
wavemngr('add',FN,FSN,WT,NUMS,FILE,B)
wavemngr('add',FN,FSN,WT,{NUMS,TYPNUMS},FILE)
wavemngr('add',FN,FSN,WT,{NUMS,TYPNUMS},FILE,B)
```

Description

wavemngr is a type of wavelets manager. It allows you to add, delete, restore, or read wavelets.

```
wavemngr('add',FN,FSN,WT,NUMS,FILE) or
wavemngr('add',FN,FSN,WT,NUMS,FILE,B) or wavemngr('add',FN,FSN,WT,
{NUMS,TYPNUMS},FILE) or wavemngr('add',FN,FSN,WT,
{NUMS,TYPNUMS},FILE,B), add a new wavelet family to the toolbox.
```

FN = Family Name (string)

FSN = Family Short Name (string of length equal or less than four characters)

WT defines the wavelet type:

- WT = 1, for orthogonal wavelets
- WT = 2, for biorthogonal wavelets
- WT = 3, for wavelet with scaling function
- WT = 4, for wavelet without scaling function
- WT = 5, for complex wavelet without scaling function

If the family contains a single wavelet, NUMS = ' '.

Examples:

mexh j	
--------	--

monl	
morl	

If the wavelet is member of a finite family of wavelets, NUMS is a string containing a blank separated list of items representing wavelet parameters.

Example:

bior	NUMS = '1.1	1.3	4.4 5.5	6.8'

If the wavelet is part of an infinite family of wavelets, NUMS is a string containing a blank separated list of items representing wavelet parameters, terminated by the special sequence **.

Examples:

db	NUMS =	: '1	2	3	4	5	6	7	8	9	10	** '
shan	NUMS =	: '1	-1.5	1	- 1	1 -	0.5	1	-0.	1	2-3	**

In these last two cases, TYPNUMS specifies the wavelet parameter input format: 'integer' or 'real' or 'string'; the default value is 'integer'.

Examples:

db	TYPNUMS = 'integer'
bior	TYPNUMS = 'real'
shan	TYPNUMS = 'string'

FILE = MAT-file or code file name (string). See usage in the "Examples" section.

B = [lb ub] specifies lower and upper bounds of effective support for wavelets of type = 3, 4, or 5.

This option is fully documented in "Adding Your Own Wavelets" in the User's Guide.

wavemngr('del',N), deletes a wavelet or a wavelet family. N is the Family Short Name or the Wavelet Name (in the family). N is a string.

wavemngr('restore') or wavemngr('restore', IN2) restores previous or initial wavelets. If nargin = 1, the previous wavelets.asc ASCII-file is restored; otherwise the initial wavelets.asc ASCII-file is restored. Here IN2 is a dummy argument.

OUT1 = wavemngr('read') returns all wavelet family names.

OUT1 = wavemngr('read', IN2) returns all wavelet names, IN2 is a dummy argument.

OUT1 = wavemngr('read_asc') reads wavelets.asc ASCII-file and returns all wavelets information.

```

In the following example, new compactly supported orthogonal wavelets are added to the toolbox. These wavelets, which are a slight generalization of the Daubechies wavelets, are based on the use of Bernstein polynomials and are due to Kateb and Lemarié in an unpublished work.

Note The files used in this example can be found in the wavedemo folder.

```
% Add new family of orthogonal wavelets.
% You must define:
%
%
      Family Name:
                            Lemarie
%
      Family Short Name:
                             lem
%
      Type of wavelet:
                             1 (orth)
      Wavelets numbers:
                             1 2 3 4 5
%
%
      File driver:
                             lemwavf
%
%
      The function lemwavf.m must be as follows:
%
      function w = lemwavf(wname)
%
      where the input argument wname is a string:
%
      wname = 'lem1' or 'lem2' \dots i.e.,
      wname = sh.name + number
%
%
      and w the corresponding scaling filter.
      The addition is obtained using:
wavemngr('add','Lemarie','lem',1,'1 2 3 4 5','lemwavf');
% The ascii file 'wavelets.asc' is saved as
```

```
% 'wavelets.prv', then it is modified and

% Add new family of orthogonal wavelets.
wavemngr('add','Lemarie','lem',1,'1 2 3','lemwavf');
% All command line capabilities are available for
% the new wavelets.
% Example 1: compute the four associated filters.
[Lo D,Hi D,Lo R,Hi R] = wfilters('lem3');
% Example 2: compute scale and wavelet functions.
[phi,psi,xval] = wavefun('lem3');
% Add a new family of orthogonal wavelets: special form
% for the GUI mode.
% The file lemwavf allows you to compute the filter for
% any order. If you want to get a popup of the form
% 1 2 3 **, associated with the family, then wavelets are
% appended for GUI mode using:
```

```
wavemngr('restore',0);
wavemngr('add','Lemarie','lem',1,'1 2 3 **','lemwavf');
% After this sequence, all GUI capabilities are available for
% the new wavelets.
% Note that the last command allows a short cut in the
% order definition only if possible orders are integers.
```

Caution wavemngr works on the current folder. If you add a new wavelet family, it is available in this folder only. Refer to, "Adding Your Own Wavelets", in the User's Guide.

Limitations

wavemngr allows you to add a new wavelet. You must verify that it is truly a wavelet. No check is performed either about this point or about the type of the new wavelet.

wavenames

Wavelet names for LWT

Syntax

```
W = wavenames(T)
```

Description

W = wavenames(T) returns a cell array that contains the name of all wavelets of type T. The valid values for T are

- · 'all' all wavelets
- 'lazy' "lazy" wavelet
- · 'orth' orthogonal wavelets
- · 'bior' biorthogonal wavelets

W = wavenames is equivalent to W = wavenames('all').

waverec

Multilevel 1-D wavelet reconstruction

Syntax

```
X = waverec(C,L,Lo_R,Hi_R)
X = waverec(C,L,'wname')
X = appcoef(C,L,'wname',0)
```

Description

waverec performs a multilevel one-dimensional wavelet reconstruction using either a specific wavelet ('wname', see wfilters) or specific reconstruction filters (Lo_R and HiR).

Note waverec supports only Type 1 (orthogonal) or Type 2 (biorthogonal) wavelets.

X = waverec(C, L, 'wname') reconstructs the signal X based on the multilevel wavelet decomposition structure [C, L] and wavelet 'wname'. (For information about the decomposition structure, see wavedec.)

X = waverec(C,L,Lo_R,Hi_R) reconstructs the signal X as above, using the reconstruction filters you specify. Lo_R is the reconstruction low-pass filter and Hi_R is the reconstruction high-pass filter.

```
Note that X = waverec(C, L, 'wname') is equivalent to X = appcoef(C, L, 'wname', 0).
```

Examples

```
% The current extension mode is zero-padding (see dwtmode).
% Load original one-dimensional signal.
load leleccum; s = leleccum(1:3920); ls = length(s);
```

```
% Perform decomposition of signal at level 3 using db5.
[c,1] = wavedec(s,3,'db5');
% Reconstruct s from the wavelet decomposition structure [c,1].
a0 = waverec(c,1,'db5');
% Check for perfect reconstruction.
err = norm(s-a0)
err =
    3.2079e-09
```

See Also

appcoef | idwt | wavedec

waverec2

Multilevel 2-D wavelet reconstruction

Syntax

```
X = waverec2(C,S,'wname')
X = waverec2(C,S,Lo_R,Hi_R)
waverec2(wavedec2(X,N,'wname'),'wname')
X = waverec2(C,S,'wname')
X = appcoef2(C,S,'wname',0)
```

Description

X = waverec2(C,S,'wname') performs a multilevel wavelet reconstruction of the matrix X based on the wavelet decomposition structure [C,S]. For detailed storage information, see wavedec2. 'wname' is a string containing the name of the wavelet. See wfilters for more information.

Instead of specifying the wavelet name, you can specify the filters.

- X = waverec2(C,S,Lo_R,Hi_R), Lo_R is the reconstruction low-pass filter
- Hi R is the reconstruction high-pass filter.

waverec2 is the inverse function of wavedec2 in the sense that the abstract statement waverec2(wavedec2(X,N,'wname'),'wname') returns X.

```
X = waverec2(C,S,'wname') is equivalent to X = appcoef2(C,S,'wname',0).
```

Examples

```
% The current extension mode is zero-padding (see dwtmode).
% Load original image.
load woman;
% X contains the loaded image.
% Perform decomposition at level 2
% of X using sym4.
```

```
[c,s] = wavedec2(X,2,'sym4');
% Reconstruct X from the wavelet
% decomposition structure [c,s].
a0 = waverec2(c,s,'sym4');
% Check for perfect reconstruction.
max(max(abs(X-a0)))
ans =
    2.5565e-10
```

More About

Tips

If C and S are obtained from an indexed image analysis or a truecolor image analysis, X is an m-by-n matrix or an m-by-n-by-3 array, respectively.

For more information on image formats, see the image and imfinfo reference pages.

appcoef2 | idwt2 | wavedec2

waverec3

Multilevel 3-D wavelet reconstruction

Syntax

```
X = waverec3(WDEC)
C = waverec3(WDEC,TYPE,N)
X = waverec3(WDEC,'a',0)
X = waverec3(WDEC,'ca',0)
C = waverec3(WDEC,TYPE)
C = waverec3(WDEC,TYPE,N)
```

Description

waverec3 performs a multilevel 3-D wavelet reconstruction starting from a multilevel 3-D wavelet decomposition.

X = waverec3(WDEC) reconstructs the 3-D array X based on the multilevel wavelet decomposition structure WDEC. You can also use waverec3 to extract coefficients from a 3-D wavelet decomposition.

WDEC is a structure with the fields shown in the table.

C = waverec3(WDEC, TYPE, N) reconstructs the multilevel components at level N of a 3-D wavelet decomposition. N must be a positive integer less than or equal to the level of the decomposition.

Valid values for TYPE are:

- A group of three characters 'xyz', one per direction, with 'x','y' and 'z' selected
 in the set {'a', 'd', 'l', 'h'} or in the corresponding uppercase set {'A','D', 'L',
 'H'}), where 'A' (or 'L') is a low-pass filter and 'D' (or 'H') is a high-pass filter.
- The char 'd' (or 'h' or 'D' or 'H') gives the sum of all the components different from the low-pass.
- The char 'a' (or 'l' or 'A' or 'L') gives the low-pass component (the approximation at level N).

For extraction, the valid values for TYPE are the same but prefixed by 'C' or 'C'.

X = waverec3(WDEC, 'a', 0) or X = waverec3(WDEC, 'ca', 0) is equivalent to X = waverec3(WDEC). X = waverec3(WDEC) is a reconstruction of the coefficients in WDEC at level 0.

C = waverec3(WDEC, TYPE) is equivalent to C = waverec3(WDEC, TYPE, N) with N equal to the level of the decomposition.

sizeINI	Size of the three-dimensional array X
level	Level of the decomposition
mode	Name of the wavelet transform extension mode
filters	Structure with 4 fields, LoD, HiD, LoR, and HiR, which contain the filters used for DWT
dec	N x 1 cell array containing the coefficients of the decomposition. N is equal to 7*WDEC.level+1. dec{1} contains the lowpass component (approximation) at the level of the decomposition. The approximation is equivalent to the filtering operations 'LLL'. dec{k+2},,dec{k+8} with k = 0,7,14,,7* (WDEC.level-1) contain the 3-D wavelet coefficients for the multiresolution starting with the coarsest level when k=0. For example, if WDEC.level=3, dec{2},,dec{8} contain the wavelet coefficients for level 3 (k=0), dec{9},,dec{15} contain the wavelet coefficients for level 2 (k=7), and dec{16},,dec{22} contain the wavelet coefficients for level 1 (k=7* (WDEC.level-1)). At each level, the wavelet coefficients in dec{k+2},,dec{k+8} are in the following order: 'HLL','LHL','HHL','LLH','HLH','LHH','HHH'. The strings give the order in which the separable filtering operations are applied from left to right. For example, 'LHH' means that the lowpass (scaling) filter with downsampling is applied to the rows of X, followed by the highpass (wavelet)

	filter with downsampling applied to the columns of X. Finally, the highpass filter with downsampling is applied to the 3rd dimension of X.
sizes	Successive sizes of the decomposition components

Examples

Perfect Reconstruction with 3-D Discrete Wavelet Transform

Construct a 3-D matrix, obtain the wavelet transform down to level 2 using the db2 wavelet, and reconstruct the matrix to verify perfect reconstruction.

Create 3-D matrix.

```
M = magic(8);
X = repmat(M,[1 1 8]);
```

Obtain the 3-D discrete wavelet transform of the matrix and reconstruct the input based on the 3-D approximation and detail coefficients.

```
wd = wavedec3(X,2,'db2');
XR = waverec3(wd);
```

Verify perfect reconstruction using the wavelet decomposition down to level 2.

```
err1 = max(abs(X(:)-XR(:)))
```

Verify that the data matrix is the sum of the approximation and the details from levels 2 and 1.

```
A = waverec3(wd, 'LLL');
% Reconstruct the sum of components different from
% the lowpass component.
D = waverec3(wd, 'd');
% Check that X = A + D.
err2 = max(abs(X(:)-A(:)-D(:)))
```

Compare waverec3 and idwt3

Compare level-1 reconstructions based on the filtering operations 'LLH' using idwt3 and waverec3.

```
dwtOut = dwt3(X,'db2');
Xr = idwt3(dwtOut,'LLH');
Xrec = waverec3(wd,'LLH',1);
norm(Xr(:)-Xrec(:))
```

See Also

idwt3 | waveinfo | wavedec3

Introduced in R2010a

wavsupport

Wavelet support

Syntax

```
[LB,UB] = wavsupport(wname)
```

Description

[LB,UB] = wavsupport(wname) returns the lower bound, LB, and upper bound, UB, of the support for the wavelet specified by wname. wname is any valid wavelet. For real-valued wavelets with and without scaling functions and complex-valued wavelets without scaling functions (wavelets type 3,4, and 5), the bounds indicate the effective support of the wavelet. For orthogonal and biorthogonal wavelets (type 1 and type 2), the lower and upper bounds are -0.5*(LF-1) and 0.5*(LF-1), where LF is the length of the wavelet filter.

Examples

Support of Haar wavelet:

```
[LB, UB] = wavsupport('haar');
LowerBound = -0.5*(2-1);
UpperBound = 0.5*(2-1);
% Compare [LB,UB] and [LowerBound, UpperBound]
```

Effective support of complex-valued Gaussian wavelet:

```
[LB,UB] = wavsupport('cgau3');
```

wavemngr

Introduced in R2010b

wbmpen

Penalized threshold for wavelet 1-D or 2-D de-noising

Syntax

```
THR = wbmpen(C,L,SIGMA,ALPHA)
wbmpen(C,L,SIGMA,ALPHA,ARG)
```

Description

THR = wbmpen(C,L,SIGMA,ALPHA) returns global threshold THR for de-noising. THR is obtained by a wavelet coefficients selection rule using a penalization method provided by Birgé-Massart.

[C,L] is the wavelet decomposition structure of the signal or image to be de-noised.

SIGMA is the standard deviation of the zero mean Gaussian white noise in de-noising model (see wnoisest for more information).

ALPHA is a tuning parameter for the penalty term. It must be a real number greater than 1. The sparsity of the wavelet representation of the de-noised signal or image grows with ALPHA. Typically ALPHA = 2.

THR minimizes the penalized criterion given by

let t* be the minimizer of

```
crit(t) = -sum(c(k)^2, k \le t) + 2*SIGMA^2*t*(ALPHA + log(n/t))
```

where c(k) are the wavelet coefficients sorted in decreasing order of their absolute value and n is the number of coefficients; then THR= $|c(t^*)|$.

wbmpen(C,L,SIGMA,ALPHA,ARG) computes the global threshold and, in addition, plots three curves:

```
• 2*SIGMA^2*t*(ALPHA + log(n/t))
```

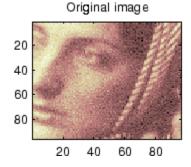

```
    sum(c(k)^2,k²t)
    crit(t)
```

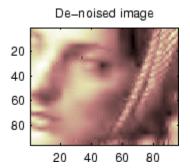

Examples

```
% Example 1: Signal de-noising.
% Load noisy bumps signal.
load noisbump; x = noisbump;
% Perform a wavelet decomposition of the signal
% at level 5 using sym6.
wname = 'sym6'; lev = 5;

Introduced before R2006a

wcodemat

Extended pseudocolor matrix scaling

Syntax

```
Y = wcodemat(X)
Y = wcodemat(X,NBCODES)
Y = wcodemat(X,NBCODES,OPT)
Y = wcodemat(X,NBCODES,OPT,ABSOL)
```

Description

wcodemat rescales an input matrix to a specified range for display. If the specified range is the full range of the current colormap, wcodemat is similar in behavior to imagesc.

```
Y = wcodemat(X) rescales the matrix X to integers in the range [1,16].
```

Y = wcodemat(X,NBCODES) rescales the input X as integers in the range [1,NBCODES]. The default value of NBCODES is 16.

Y = wcodemat(X,NBCODES,OPT) rescales the matrix along the dimension specified by OPT. Valid strings for OPT are: 'column' (or 'c'), 'row' (or 'r'), and 'mat' (or 'm'). 'rows' scales X row-wise, 'column' scales X column-wise, and 'mat' scales X globally. The default value of OPT is 'mat'.

Y = wcodemat(X,NBCODES,OPT,ABSOL) rescales the input matrix X based on the absolute values of the entries in X if ABSOL is nonzero, or based on the signed values of X if ABSOL is equal to zero. The default value of ABSOL is 1.

Examples

Scale level-one approximation coefficients globally to the full range of the colormap.

```
load woman;
% Get the range of the colormap
NBCOL = size(map,1);
```

```
% Obtain the 2D dwt using the Haar wavelet
[cA1,cH1,cV1,cD1] = dwt2(X,'db1');
% Display without scaling
image(cA1);
colormap(map);
title('Unscaled Image');
figure;
% Display with scaling
image(wcodemat(cA1,NBCOL));
colormap(map);
title('Scaled Image');
```

Introduced before R2006a

wcoher

Wavelet coherence

Syntax

```
WCOH = wcoher(Sig1,Sig2,Scales,wname)
WCOH = wcoher(...,Name,Value)
[WCOH,WCS] = wcoher(...)
[WCOH,WCS,CWT_S1,CWT_S2] = wcoher(...)
[...] = wcoh(...,'plot')
```

Description

WCOH = wcoher(Sig1,Sig2,Scales,wname) returns the wavelet coherence for the input signals Sig1 and Sig2 using the wavelet specified in wname at the scales in Scales. The input signals must be real-valued and equal in length.

WCOH = wcoher(..., Name, Value) returns the wavelet coherence with additional options specified by one or more Name, Value pair arguments.

```
[WCOH, WCS] = wcoher(...) returns the wavelet cross spectrum.
```

[WCOH, WCS, CWT_S1, CWT_S2] = wcoher(...) returns the continuous wavelet transforms of Sig1 and Sig2.

[...] = wcoh(..., 'plot') displays the modulus and phase of the wavelet cross spectrum.

Input Arguments

Sig1

A real-valued one-dimensional input signal. Sig1 is a row or column vector.

Sig2

A real-valued one-dimensional input signal. Sig2 is a row or column vector.

Scales

Scales is a vector of real-valued, positive scales at which to compute the wavelet coherence.

wname

Wavelet used in the wavelet coherence. wname is any valid wavelet name.

Name-Value Pair Arguments

'asc'

Scale factor for arrows in quiver plot. wcoher represents the phase using quiver. asc corresponds to the scale input argument in quiver.

Default: 1

'nas'

Number of arrows in scale. Together with the number of scales, nas determines the spacing between the y coordinates in the input to quiver. The y input to quiver is 1:length(Scales)/(nas-1):Scales(end)

Default: 20

'nsw'

Length of smoothing window in scale. **nsw** is a positive integer that specifies the length of a moving average filter in scale.

Default: 1

'ntw'

Length of smoothing window in time. ntw is a positive integer that specifies the length of a moving average filter in time.

```
Default: min[20,0.05*length(Sig1)]
```

'plot'

Type of plot. plot is one of the following strings:

• 'cwt'

Displays the continuous wavelet transforms of signals 1 and 2.

'wcs'

Displays the wavelet cross spectrum.

· 'wcoh'

Displays the phase of the wavelet cross spectrum.

• 'all'

Displays all plots in separate figures.

Output Arguments

WCOH

Wavelet coherence.

WCS

Wavelet cross spectrum.

CWT_S1

Continuous wavelet transform of signal 1.

CWT_S2

Continuous wavelet transform of signal 2.

Examples

Wavelet coherence of sine waves in noise with delay:

```
t = linspace(0,1,2048);
x = sin(16*pi*t)+0.5*randn(1,2048);
y = sin(16*pi*t+pi/4)+0.5*randn(1,2048);
```

```
wname = cgau3;
scales = 1:512;
ntw = 21; % smoothing parameter
% Display the modulus and phased of the wavelet cross spectrum.
wcoher(x,y,scales,wname,'ntw',ntw,'plot');
Sine wave and Doppler signal:
t = linspace(0,1,1024);
x = -\sin(8*pi*t) + 0.4*randn(1,1024);
x = x/max(abs(x));
y = wnoise('doppler',10);
wname = cgau3;
scales = 1:512;
ntw = 21; % smoothing parameter
% Display of the CWT of the two signals.
wcoher(x,y,scales,wname,'ntw',ntw,'plot','cwt');
% Display of the wavelet cross spectrum.
wcoher(x,y,scales,wname,'ntw',ntw,'nsw',1,'plot','wcs');
% Display of the modulus and phased of the wavelet cross spectrum.
wcoher(x,y,scales,wname,'ntw',ntw,'plot');
```

More About

Wavelet Cross Spectrum

The wavelet cross spectrum of two time series, *x* and *y* is:

$$C_{xy}(a,b) = S(C_x^*(a,b)C_y(a,b))$$

where $C_x(a,b)$ and $C_y(a,b)$ denote the continuous wavelet transforms of x and y at scales a and positions b. The superscript * is the complex conjugate and S is a smoothing operator in time and scale.

For real-valued time series, the wavelet cross spectrum is real-valued if you use a real-valued analyzing wavelet, and complex-valued if you use a complex-valued analyzing wavelet.

Wavelet Coherence

The wavelet coherence of two time series *x* and *y* is:

$$\frac{S(\boldsymbol{C}_{\boldsymbol{x}}^{*}(\boldsymbol{a},\boldsymbol{b})\boldsymbol{C}_{\boldsymbol{y}}(\boldsymbol{a},\boldsymbol{b}))}{\sqrt{S(\mid\boldsymbol{C}_{\boldsymbol{x}}(\boldsymbol{a},\boldsymbol{b})\mid^{2})}\sqrt{S(\mid\boldsymbol{C}_{\boldsymbol{y}}(\boldsymbol{a},\boldsymbol{b})\mid^{2})}}$$

where $C_x(a,b)$ and $C_y(a,b)$ denote the continuous wavelet transforms of x and y at scales a and positions b. The superscript * is the complex conjugate and S is a smoothing operator in time and scale.

For real-valued time series, the wavelet coherence is real-valued if you use a real-valued analyzing wavelet, and complex-valued if you use a complex-valued analyzing wavelet.

Wavelet Coherence

wcompress

True compression of images using wavelets

Syntax

```
wcompress('c',X,SAV_FILENAME,COMP_METHOD)
wcompress(...,'ParName1',ParVal1,'ParName2',ParVal2,...)
[COMPRAT,BPP] = wcompress('c',...)
XC = wcompress('u',SAV_FILENAME)
XC = wcompress('u',SAV_FILENAME,'plot')
XC = wcompress('u',SAV_FILENAME,'step')
```

Description

The wcompress command performs either compression or uncompression of grayscale or truecolor images.

More theoretical information on true compression is in "True Compression for Images" of the Wavelet Toolbox User's Guide.

Compression

wcompress('c',X,SAV_FILENAME,COMP_METHOD) compresses the image X using the compression method COMP_METHOD.

The compressed image is saved in the file SAV_FILENAME. X can be either a 2-D array containing an indexed image or a 3-D array of uint8 containing a truecolor image.

wcompress ('c', FILENAME,...) loads the image X from the file FILENAME which is a MATLAB Supported Format (MSF) file: MAT-file or other image files (see imread).

wcompress ('C', I,...) converts the indexed image $X = I\{1\}$ to a truecolor image Y using the colormap map = $I\{2\}$ and then compresses Y.

The valid compression methods are divided in three categories.

1 Progressive Coefficients Significance Methods (**PCSM**):

MATLAB Name	Compression Method Name
'ezw'	Embedded Zerotree Wavelet
'spiht'	Set Partitioning In Hierarchical Trees
'stw'	Spatial-orientation Tree Wavelet
'wdr'	Wavelet Difference Reduction
'aswdr'	Adaptively Scanned Wavelet Difference Reduction
'spiht_3d'	Set Partitioning In Hierarchical Trees 3D for truecolor images

For more details on these methods, see the references and especially Walker and also Said and Pearlman.

1 Coefficients Thresholding Methods (**CTM-1**):

MATLAB Name	Compression Method Name
'1v1_mmc'	Subband thresholding of coefficients and Huffman encoding

For more details on this method, see the Strang and Nguyen reference.

1 Coefficients Thresholding Methods (**CTM-2**):

MATLAB Name	Compression Method Name
'gbl_mmc_f'	Global thresholding of coefficients and fixed encoding
'gbl_mmc_h'	Global thresholding of coefficients and Huffman encoding

Note The Discrete Wavelet Transform uses the periodized extension mode. Each of the two dimensions of the image must be a power of 2.

All the compression methods use parameters which have default values. You can change these values using the following syntax:

```
wcompress(..., 'ParName1', ParVal1, 'ParName2', ParVal2,...)
```

Some of the parameters are related to display or to data transform functionalities. The others are linked to the compression process itself.

Data transform parameters

• 'ParName' = 'wname' or 'WNAME' sets the wavelet name.

ParVal is a string (see waveletfamilies). The default for is bior 4.4

• 'ParName' = 'level' or 'LEVEL' sets the level of decomposition.

ParVal is an integer such that: $1 \le level \le levmax$ which is the maximum possible level (see wmaxlev).

The default level depends on the method:

- for **PCSM** methods level is equal to levmax.
- for CTM methods level is equal to fix(levmax/2)
- ParName' = 'it' or 'IT' sets Image type Transform.

ParVal must be one of the following strings:

'n': no transformation (default), image type (truecolor or grayscale) is automatically detected

'g': grayscale transformation type.

'c': color transformation type (RGB uint8).

 'ParName' = 'cc' or 'CC' sets Color Conversion parameter if X is a truecolor image.

ParVal must be one of the following strings:

```
'rgb' or 'none': No conversion (default).
```

'yuv': YUV color space transform.

'klt': Karhunen-Loeve transform.

'vig': YIQ color space transform.

'xyz': CIEXYZ color space transform.

Parameter for Progressive Coefficients Significance Methods (PCSM)

• 'ParName' = 'maxloop' or 'MAXLOOP' sets the maximum number of steps for the compression algorithm.

ParVal must be a positive integer or Inf (default is 10).

Parameters for Coefficients Thresholding Methods (CTM-1)

Either of the following parameters may be used:

• 'ParName' = 'bpp' or 'BPP' sets the bit-per-pixel ratio.

ParVal must be such that $0 \le ParVal \le 8$ (grayscale) or 24 (truecolor).

• 'ParName' = 'comprat' or 'COMPRAT' sets the compression ratio.

ParVal must be such that $0 \le ParVal \le 100$.

Parameters for Coefficients Thresholding Methods (CTM-2)

Two parameters may be used. The first is related to the threshold and the second is the number of classes for quantization.

The first one may be chosen among the five following parameters:

 'ParName' = 'threshold' or 'THRESHOLD' sets the threshold value for compression.

ParVal must be a positive (or zero) real number.

• 'ParName' = 'nbcfs' or 'NBCFS' sets the number of preserved coefficients in the wavelet decomposition.

ParVal must be an integer such that: $0 \le ParVal \le total$ number of coefficients of wavelet decomposition.

• 'ParName' = 'percfs' or 'PERCFS' sets the percentage of preserved coefficients in the wavelet decomposition.

ParVal must be a real number such that: $0 \le ParVal \le 100$.

• 'ParName' = 'bpp' or 'BPP' sets the bit-per-pixel ratio.

ParVal must be such that: $0 \le ParVal \le 8$ (grayscale) or 24 (truecolor)

• 'ParName' = 'comprat' or 'COMPRAT' sets the compression ratio.

```
ParVal must be such that: 0 \le ParVal \le 100.
```

The second parameter sets the number of classes for quantization:

• 'ParName' = 'nbclas' or 'NBCLAS' sets the number of classes.

ParVal must be a real number such that: $2 \le ParVal \le 200$.

Display parameter

'ParName' = 'plotpar' or 'PLOTPAR' sets the plot parameter.

ParVal must be one of the following strings or numbers:

```
'plot' or 0: plots only the compressed image.
```

'step' or 1: displays each step of the encoding process (only for **PCSM** methods).

[COMPRAT,BPP] = wcompress('c',...) returns the compression ratio COMPRAT and the bit_per_pixel ratio BPP.

Uncompression

XC = wcompress('u', SAV_FILENAME) uncompresses the file SAV_FILENAME and returns the image XC. Depending on the initial compressed image, XC can be a 2-D array containing either an indexed image or a 3-D array of uint8 containing a truecolor image.

```
XC = wcompress('u',SAV_FILENAME,'plot') plots the uncompressed image.
```

XC = wcompress('u', SAV_FILENAME, 'step') shows the step-by-step uncompression, only for **PCSM** methods.

Examples

```
% Example 1: Compression and uncompression using
% basic parameters.
```

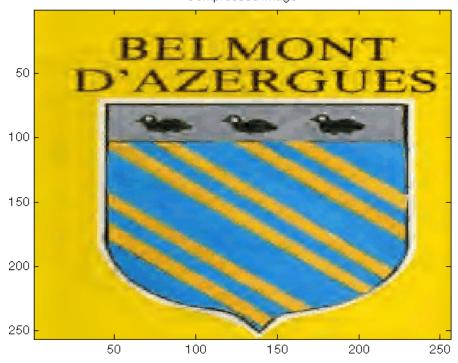

```
% This example demonstrates first how to compress the jpeg % image arms.jpg using the 'stw' compression method and % save it to the file: 'comp_arms.wtc'.

wcompress('c','arms.jpg','comp_arms.wtc','stw');

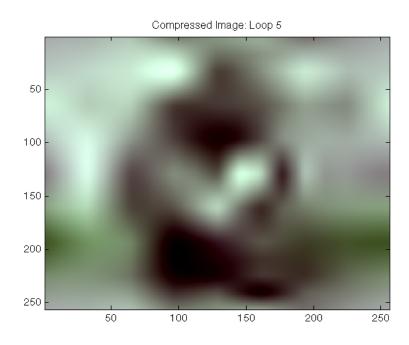

% Then, it shows how to load the stored image from % the file 'comp_arms.wtc' and to display the step by % step uncompression leading to the final image below.

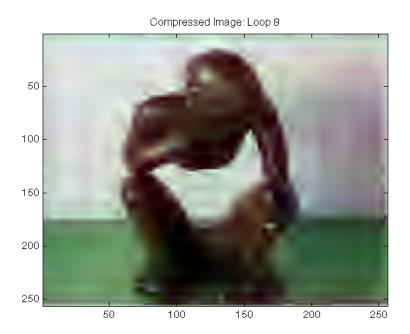

wcompress('u','comp arms.wtc','step');
```

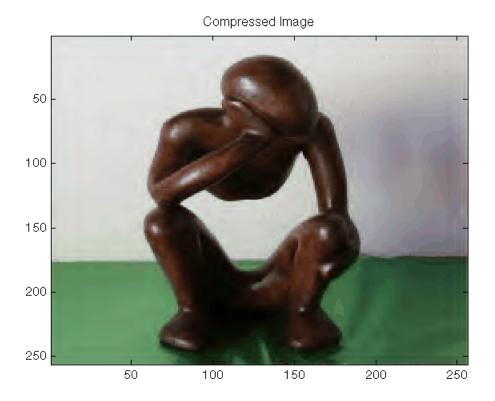

Compressed Image

- % Example 2: Compression and uncompression using
- % advanced parameters.
- $\ensuremath{\text{\%}}$ This example demonstrates how to compress a jpeg

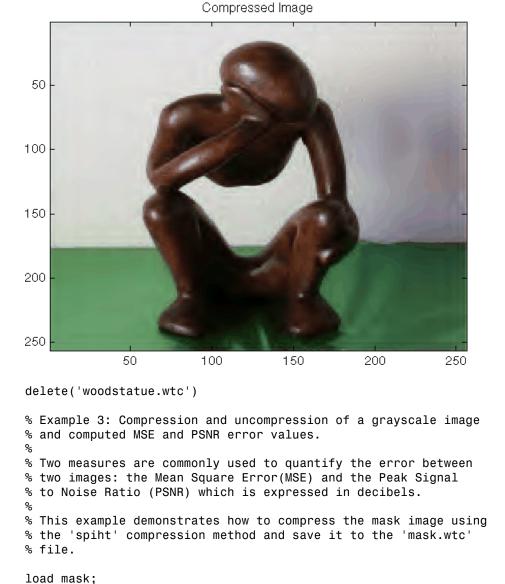

\$ Then, it shows how to load the stored image from the \$ file 'woodstatue.wtc' and to display the step by step \$ uncompression process.

wcompress('u','woodstatue.wtc','step');

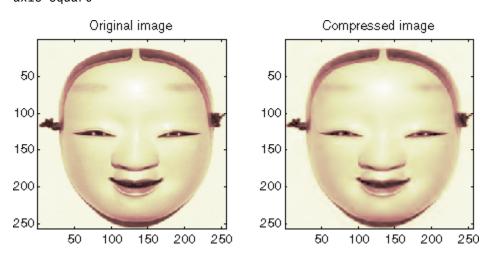

[cr,bpp] = wcompress('c',X,'mask.wtc','spiht','maxloop',12)

cr =

2.8336

```
bpp =
     0.2267
% Then, it shows how to load the stored image from the file
% 'mask.wtc', uncompress it and delete the file 'mask.wtc'.

Xc = wcompress('u','mask.wtc');
delete('mask.wtc')
% The orginal and compressed images are displayed.
colormap(pink(255))
subplot(1,2,1); image(X); title('Original image')
axis square
subplot(1,2,2); image(Xc); title('Compressed image')
axis square
```

% Finally the MSE and the PSNR are computed.

```
D = abs(X-Xc).^2;
mse = sum(D(:))/numel(X)

mse =
    33.6564

psnr = 10*log10(255*255/mse)
```

```
psnr =
   32.8601
% Example 4: Compression and uncompression of a truecolor image
% and computed MSE and PSNR error values.
% Compression parameters are the same as those used for example 3,
% but using the 'spiht 3d' method give better performance yet.
X = imread('wpeppers.jpg');
[cr,bpp] = wcompress('c',X,'wpeppers.wtc','spiht','maxloop',12)
cr =
    1.6527
bpp =
    0.3966
Xc = wcompress('u', 'wpeppers.wtc');
delete('wpeppers.wtc')
subplot(1,2,1); image(X); title('Original image'), axis square
subplot(1,2,2); image(Xc); title('Compressed image'), axis square

wdcbm

Thresholds for wavelet 1-D using Birgé-Massart strategy

Syntax

```
[THR,NKEEP] = wdcbm(C,L,ALPHA,M)
wdcbm(C,L,ALPHA)
wdcbm(C,L,ALPHA,L(1))
```

Description

[THR, NKEEP] = wdcbm(C, L, ALPHA, M) returns level-dependent thresholds THR and numbers of coefficients to be kept NKEEP, for de-noising or compression. THR is obtained using a wavelet coefficients selection rule based on the Birgé-Massart strategy.

[C,L] is the wavelet decomposition structure of the signal to be de-noised or compressed, at level j = length(L) - 2. ALPHA and M must be real numbers greater than 1.

THR is a vector of length j; THR(i) contains the threshold for level i.

NKEEP is a vector of length j; NKEEP(i) contains the number of coefficients to be kept at level i.

j, M and ALPHA define the strategy:

- At level j+1 (and coarser levels), everything is kept.
- For level i from 1 to j, the n_i largest coefficients are kept with n_i = M / (j+2-i) ALPHA.

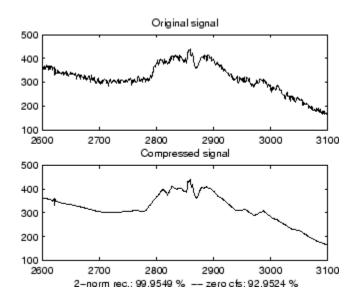

Typically ALPHA = 1.5 for compression and ALPHA = 3 for de-noising.

A default value for M is M = L(1), the number of the coarsest approximation coefficients, since the previous formula leads for i = j+1, to $n_{j+1} = M = L(1)$. Recommended values for M are from L(1) to 2*L(1).

wdcbm(C,L,ALPHA) is equivalent to wdcbm(C,L,ALPHA,L(1)).

Examples

```
% Load electrical signal and select a part of it.
load leleccum; indx = 2600:3100;
x = leleccum(indx);
% Perform a wavelet decomposition of the signal
% at level 5 using db3.
wname = 'db3'; lev = 5;
[c,1] = wavedec(x,lev,wname);
% Use wdcbm for selecting level dependent thresholds
% for signal compression using the adviced parameters.
alpha = 1.5; m = l(1);
[thr,nkeep] = wdcbm(c,l,alpha,m)
thr =
           17.1415
                       20.2599
   19.5569
                                 42.8959 15.0049
nkeep =
                             7
           2
                3
% Use wdencmp for compressing the signal using the above
% thresholds with hard thresholding.
[xd,cxd,lxd,perf0,perf12] = ...
                  wdencmp('lvd',c,1,wname,lev,thr,'h');
% Plot original and compressed signals.
subplot(211), plot(indx,x), title('Original signal');
subplot(212), plot(indx,xd), title('Compressed signal');
xlab1 = ['2-norm rec.: ',num2str(perfl2)];
xlab2 = [' % -- zero cfs: ',num2str(perf0), ' %'];
xlabel([xlab1 xlab2]);

wdcbm2

Thresholds for wavelet 2-D using Birgé-Massart strategy

Syntax

```
[THR,NKEEP] = wdcbm2(C,S,ALPHA,M)
wdcbm2(C,S,ALPHA)
wdcbm2(C,S,ALPHA,prod(S(1,:)))
```

Description

[THR, NKEEP] = wdcbm2(C,S,ALPHA,M) returns level-dependent thresholds THR and numbers of coefficients to be kept NKEEP, for de-noising or compression. THR is obtained using a wavelet coefficients selection rule based on the Birgé-Massart strategy.

[C,S] is the wavelet decomposition structure of the image to be de-noised or compressed, at level j = size(S,1)-2.

ALPHA and M must be real numbers greater than 1.

THR is a matrix 3 by j; THR(:,i) contains the level dependent thresholds in the three orientations: horizontal, diagonal, and vertical, for level i.

NKEEP is a vector of length j; NKEEP(i) contains the number of coefficients to be kept at level i.

j, M and ALPHA define the strategy:

- At level j+1 (and coarser levels), everything is kept.
- For level i from 1 to j, the n_i largest coefficients are kept with $n_i = M$ $(j+2-i)^{ALPHA}$.

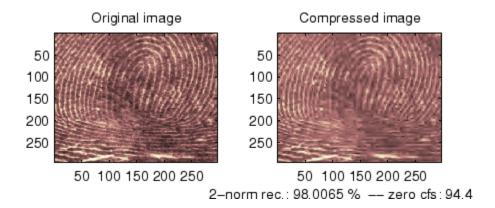

Typically ALPHA = 1.5 for compression and ALPHA = 3 for de-noising.

A default value for M is M = prod(S(1,:)), the length of the coarsest approximation coefficients, since the previous formula leads for i = j+1, to $n_{j+1} = M = prod(S(1,:))$.

```
Recommended values for M are from prod(S(1,:)) to 6*prod(S(1,:)).
wdcbm2(C,S,ALPHA) is equivalent to wdcbm2(C,S,ALPHA,prod(S(1,:))).
```

Examples

```
% Load original image.
load detfingr;
nbc = size(map, 1);
% Perform a wavelet decomposition of the image
% at level 3 using sym4.
wname = 'sym4'; lev = 3;
[c,s] = wavedec2(X,lev,wname);
% Use wdcbm2 for selecting level dependent thresholds
% for image compression using the adviced parameters.
alpha = 1.5; m = 2.7*prod(s(1,:));
[thr,nkeep] = wdcbm2(c,s,alpha,m)
thr =

wdecenergy

Multisignal 1-D decomposition energy distribution

Syntax

```
[E,PEC,PECFS] = wdecenergy(DEC)
[E,PEC,PECFS,IDXSORT,LONGS] = wdecenergy(DEC,'sort')
[E,PEC,PECFS] = wdecenergy(DEC,OPTSORT,IDXSIG)
[E,PEC,PECFS,IDXSORT,LONGS] = wdecenergy(DEC,OPTSORT,IDXSIG)
```

Description

[E,PEC,PECFS] = wdecenergy (DEC) computes the vector E that contains the energy (L2-Norm) of each decomposed signal, the matrix PEC that contains the percentage of energy for each wavelet component (approximation and details) of each signal, and the matrix PECFS that contains the percentage of energy for each coefficient.

- E(i) is the energy (L2-norm) of the ith signal.
- PEC(i,1) is the percentage of energy for the approximation of level MAXLEV = DEC.level of the ith signal.
- PEC(i,j), j=2,...,MAXLEV+1 is the percentage of energy for the detail of level (MAXLEV+1-j) of the ith signal.
- PECFS(i,j), is the percentage of energy for jth coefficients of the ith signal.

[E,PEC,PECFS,IDXSORT,LONGS] = wdecenergy(DEC, 'sort') returns PECFS sorted (by row) in ascending order and an index vector IDXSORT.

- · Replacing 'sort' by 'ascend' returns the same result.
- Replacing 'sort' by 'descend' returns PECFS sorted in descending order.

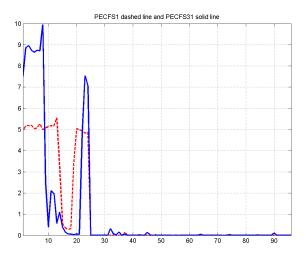

LONGS is a vector containing the lengths of each family of coefficients.

[E,PEC,PECFS] = wdecenergy(DEC,OPTSORT,IDXSIG) returns the values for the signals whose indices are given by the IDXSIG vector.

[E,PEC,PECFS,IDXSORT,LONGS] = wdecenergy(DEC,OPTSORT,IDXSIG) returns the values for the signals whose indices are given by the IDXSIG vector, the index

vector IDXSORT, and LONGS, which is a vector containing the lengths of each family of coefficients. Valid values for OPTSORT are 'none', 'sort', 'ascend', 'descend'.

wden

Automatic 1-D de-noising

Syntax

```
XD = wden(X,TPTR,SORH,SCAL,N,'wname')
XD = wden(C,L,TPTR,SORH,SCAL,N,'wname')
XD = wden(W,'modwtsqtwolog',SORH,'mln',N,WNAME)
[XD,CXD] = wden(...)
[XD,CXD,LXD] = wden(...)
```

Description

wden is a one-dimensional de-noising function.

wden performs an automatic de-noising process of a one-dimensional signal using wavelets.

XD = wden(X,TPTR,SORH,SCAL,N,'wname') returns a de-noised version XD of input signal X obtained by thresholding the wavelet coefficients.

TPTR string contains the threshold selection rule:

- · 'rigrsure' uses the principle of Stein's Unbiased Risk.
- 'heursure' is an heuristic variant of the first option.
- 'sqtwolog' for the universal threshold $\sqrt{2\ln(ullet)}$
- 'minimaxi' for minimax thresholding (see thselect for more information)

 ${\tt SORH}~(\ 's'\ or\ 'h')~is~for~soft~or~hard~thresholding~(see~{\tt wthresh}~for~more~information).$

SCAL defines multiplicative threshold rescaling:

```
'one' for no rescaling
```

'sln' for rescaling using a single estimation of level noise based on first-level coefficients

^{&#}x27;mln' for rescaling done using level-dependent estimation of level noise

Wavelet decomposition is performed at level N and 'wname' is a string containing the name of the desired orthogonal wavelet (see wmaxlev and wfilters for more information).

XD = wden(C,L,TPTR,SORH,SCAL,N,'wname') returns the same output arguments, using the same options as above, but obtained directly from the input wavelet decomposition structure [C,L] of the signal to be de-noised, at level N and using 'wname' orthogonal wavelet.

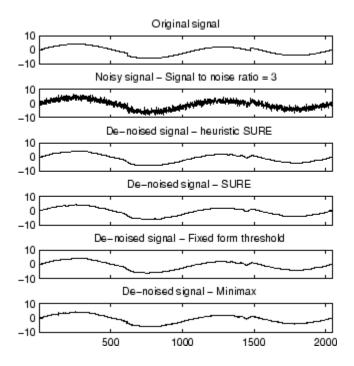

XD = wden(W, 'modwtsqtwolog', SORH, 'mln', N, WNAME) returns the denoised signal obtained by operating on the MODWT transform matrix W, where W is the output of MODWT. You must use the same wavelet in both modwt and wden.

[XD,CXD] = wden(...) returns the denoised wavelet coefficients. For DWT denoising, CXD is a vector (see wavedec). For MODWT denoising, CXD is a matrix with N+1 rows (see modwt). The number of columns is equal to the length of the input signal X.

[XD,CXD,LXD] = wden(...) returns the number of coefficients by level for DWT denoising. See wavedec for details. The LXD output is not supported for MODWT denoising. The additional output arguments [CXD,LXD] are the wavelet decomposition structure (see wavedec for more information) of the de-noised signal XD.

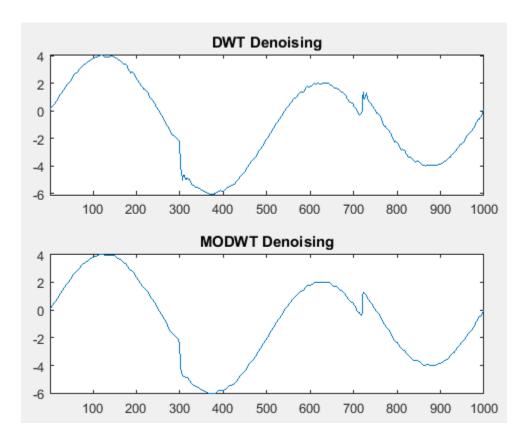

```
% The current extension mode is zero-padding (see dwtmode).
% Set signal to noise ratio and set rand seed.
snr = 3; init = 2055615866;
% Generate original signal and a noisy version adding
% a standard Gaussian white noise.
[xref,x] = wnoise(3,11,snr,init);
% De-noise noisy signal using soft heuristic SURE thresholding
% and scaled noise option, on detail coefficients obtained
% from the decomposition of x, at level 5 by sym8 wavelet.
lev = 5;
xd = wden(x,'heursure','s','one',lev,'sym8');
% Plot signals.

% If many trials are necessary, it is better to perform
% decomposition once and threshold it many times:
% decomposition.
[c,1] = wavedec(x,lev,'sym8');
% threshold the decomposition structure [c,1].
xd = wden(c,1,'minimaxi','s','sln',lev,'sym8');
% Editing some graphical properties,
% the following figure is generated.
```

Denoise a signal consisting of a 2-Hz sine wave with transients at 0.3 and 0.72 seconds. Use Donoho and Johnstone's universal threshold with level-dependent estimation of the noise. Obtain denoised versions using the DWT and MODWT. Compare the results.

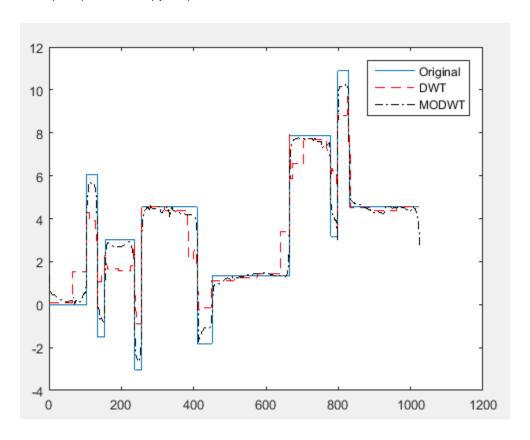

```
N = 1000;
t = linspace(0,1,N);
x = 4*sin(4*pi*t);
x = x - sign(t-.3)-sign(.72 - t);
y = x+0.15*randn(size(t));
xdDWT = wden(y,'sqtwolog','s','mln',3,'db2');
xdMODWT = wden(y,'modwtsqtwolog','s','mln',3,'db2');
subplot(2,1,1)
plot(xdDWT), title('DWT Denoising');
axis tight;
subplot(2,1,2)
plot(xdMODWT), title('MODWT Denoising');
axis tight;
```

Denoise a blocky signal using the Haar wavelet with MODWT and DWT denoising. Compare the L2 and L-infty norms of the difference between the original signal and the denoised versions.

```
[x,xn] = wnoise('blocks',10,3);
xdMODWT = wden(xn,'modwtsqtwolog','s','mln',6,'haar');
xd = wden(xn,'sqtwolog','s','mln',6,'haar');
plot(x)
hold on
plot(xd,'r--')
plot(xdMODWT,'k-.')
legend('Original','DWT','MODWT')
hold off
norm(abs(x-xd),2),
norm(abs(x-xd),Inf)
```

norm(abs(x-xdMODWT),2),
norm(abs(x-xdMODWT),Inf)

More About

Algorithms

The underlying model for the noisy signal is basically of the following form:

$$s(n) = f(n) + \sigma e(n)$$

where time n is equally spaced.

In the simplest model, suppose that e(n) is a Gaussian white noise N(0,1) and the noise level σ a is supposed to be equal to 1.

The de-noising objective is to suppress the noise part of the signal s and to recover f.

The de-noising procedure proceeds in three steps:

- 1 Decomposition. Choose a wavelet, and choose a level N. Compute the wavelet decomposition of the signal s at level N.
- **2** Detail coefficients thresholding. For each level from 1 to N, select a threshold and apply soft thresholding to the detail coefficients.
- 3 Reconstruction. Compute wavelet reconstruction based on the original approximation coefficients of level N and the modified detail coefficients of levels from 1 to N.

More details about threshold selection rules are in "Denoising and Nonparametric Function Estimation", in the User's Guide, and in the help of the thselect function. Let us point out that

- The detail coefficients vector is the superposition of the coefficients of f and the coefficients of e, and that the decomposition of e leads to detail coefficients that are standard Gaussian white noises.
- Minimax and SURE threshold selection rules are more conservative and are more
 convenient when small details of function f lie in the noise range. The two other rules
 remove the noise more efficiently. The option 'heursure' is a compromise.

In practice, the basic model cannot be used directly. This section examines the options available, to deal with model deviations. The remaining parameter scal has to be specified. It corresponds to threshold rescaling methods.

- Option scal = 'one' corresponds to the basic model.
- In general, you can ignore the noise level that must be estimated. The detail coefficients CD_I (the finest scale) are essentially noise coefficients with standard deviation equal to σ . The median absolute deviation of the coefficients is a robust estimate of σ . The use of a robust estimate is crucial because if level 1 coefficients contain f details, these details are concentrated in few coefficients to avoid signal end effects, which are pure artifacts due to computations on the edges.
- The option scal = 'sln' handles threshold rescaling using a single estimation of level noise based on the first-level coefficients.

- When you suspect a nonwhite noise e, thresholds must be rescaled by a level-dependent estimation of the level noise. The same kind of strategy is used by estimating o_{lev} level by level. This estimation is implemented in the file wnoisest, which handles the wavelet decomposition structure of the original signal s directly.
- The option scal = 'mln' handles threshold rescaling using a level-dependent estimation of the level noise.

wdencmp

De-noising or compression

Syntax

```
[XC,CXC,LXC,PERFO,PERFL2] =
wdencmp('gbl',X,'wname',N,THR,SORH,KEEPAPP)
wdencmp('gbl',C,L,'wname',N,THR,SORH,KEEPAPP)
[XC,CXC,LXC,PERFO,PERFL2] = wdencmp('lvd',X,'wname',N,THR,SORH)
[XC,CXC,LXC,PERFO,PERFL2] = wdencmp('lvd',C,L,'wname',N,THR,SORH)
[XC,CXC,LXC,PERFO,PERFL2] = wdencmp('lvd',X,'wname',N,THR,SORH)
[XC,CXC,LXC,PERFO,PERFL2] = wdencmp('lvd',C,L,'wname',N,THR,SORH)
```

Description

wdencmp is a one- or two-dimensional de-noising and compression-oriented function.

wdencmp performs a de-noising or compression process of a signal or an image, using wavelets.

```
[XC,CXC,LXC,PERFO,PERFL2] = wdencmp('gbl',X,'wname',N,THR,SORH,KEEPAPP) returns a de-noised or compressed version XC of input signal X (one- or two-dimensional) obtained by wavelet coefficients thresholding using global positive threshold THR.
```

Additional output arguments [CXC,LXC] are the wavelet decomposition structure of XC (see wavedec or wavedec2 for more information). PERFO and PERFL2 are L^2 -norm recovery and compression score in percentage.

PERFL2 = 100 * (vector-norm of CXC / vector-norm of C)² if [C,L] denotes the wavelet decomposition structure of X.

If X is a one-dimensional signal and 'wname' an orthogonal wavelet, PERFL2 is reduced to

$$\frac{100\left\|\boldsymbol{X}\boldsymbol{C}\right\|^2}{\left\|\boldsymbol{X}\right\|^2}$$

Wavelet decomposition is performed at level N and 'wname' is a string containing wavelet name (see wmaxlev and wfilters for more information). SORH ('s' or 'h') is for soft or hard thresholding (see wthresh for more information). If KEEPAPP = 1, approximation coefficients cannot be thresholded, otherwise it is possible.

wdencmp('gbl',C,L,'wname',N,THR,SORH,KEEPAPP) has the same output arguments, using the same options as above, but obtained directly from the input wavelet decomposition structure [C,L] of the signal to be de-noised or compressed, at level N and using 'wname' wavelet.

For the one-dimensional case and 'lvd' option, [XC,CXC,LXC,PERFO,PERFL2] = wdencmp('lvd',X,'wname',N,THR,SORH) or [XC,CXC,LXC,PERFO,PERFL2] = wdencmp('lvd',C,L,'wname',N,THR,SORH) have the same output arguments, using the same options as above, but allowing level-dependent thresholds contained in vector THR (THR must be of length N). In addition, the approximation is kept. Note that, with respect to wden (automatic de-noising), wdencmp allows more flexibility and you can implement your own de-noising strategy.

For the two-dimensional case and 'lvd' option, [XC,CXC,LXC,PERFO,PERFL2] = wdencmp('lvd',X,'wname',N,THR,SORH) or [XC,CXC,LXC,PERFO,PERFL2] = wdencmp('lvd',C,L,'wname',N,THR,SORH).

THR must be a matrix 3 by N containing the level-dependent thresholds in the three orientations, horizontal, diagonal, and vertical.

Like denoising, the compression procedure contains three steps:

- 1 Decomposition.
- **2** Detail coefficient thresholding. For each level from 1 to N, a threshold is selected and hard thresholding is applied to the detail coefficients.
- 3 Reconstruction.

The difference with the denoising procedure is found in step 2.

Examples

Denoise Image Using Default Global Threshold

Denoise an image in additive white Gaussian noise using the Donoho-Johnstone universal threshold.

Load the image and add white Gaussian noise.

```
load sinsin;
Y = X + 18*randn(size(X));
```

Use ddencmp to obtain the threshold and denoise the image. Plot the original image, noisy image, and denoised result.

```
[thr,sorh,keepapp] = ddencmp('den','wv',Y);
xd = wdencmp('gbl',Y,'sym4',2,thr,sorh,keepapp);
subplot(221)
imagesc(X); title('Original Image');
subplot(222);
imagesc(Y); title('Noisy Image');
subplot(223)
imagesc(xd); title('Denoised Image');
```

Denoise 1-D Signal Using Default Global Threshold

Denoise 1-D electricity consumption data using the Donoho-Johnstone global threshold.

Load the signal and select a segment for denoising.

```
load leleccum; indx = 2600:3100;
x = leleccum(indx);
```

Use **ddencmp** to determine the default global threshold and denoise the signal. Plot the original and denoised signals.

```
[thr,sorh,keepapp] = ddencmp('den','wv',x);
xd = wdencmp('gbl',x,'db3',2,thr,sorh,keepapp);
subplot(211)
plot(x); title('Original Signal');
subplot(212)
plot(xd); title('Denoised Signal');
```

wenergy

Energy for 1-D wavelet or wavelet packet decomposition

Syntax

```
[Ea,Ed] = wenergy(C,L)
E = wenergy(T)
```

Description

For a one-dimensional wavelet decomposition [C,L] (see wavedec for details), [Ea,Ed] = wenergy(C,L) returns Ea, which is the percentage of energy corresponding to the approximation and Ed, which is the vector containing the percentages of energy corresponding to the details.

For a wavelet packet tree T (see wptree, wpdec, wpdec2), E = wenergy(T) returns a vector E, which contains the percentages of energy corresponding to the terminal nodes of the tree T. In this case, wenergy is a method of the wptree object T, which overloads the previous wenergy function.

```
% Example 1: 1-D wavelet decomposition
%------
load noisbump
[C,L] = wavedec(noisbump,4,'sym4');
[Ea,Ed] = wenergy(C,L)

Ea =
    88.2860

Ed =
    2.1560    1.2286    1.4664    6.8630
```

```
% Example 2: 1-D wavelet packet decomposition
%------
load noisbump
T = wpdec(noisbump,3,'sym4');
E = wenergy(T)
E =
95.0329 1.4664 0.6100 0.6408 0.5935 0.5445 0.5154
0.5965
```

wenergy2

Energy for 2-D wavelet decomposition

Syntax

```
[Ea,Eh,Ev,Ed] = wenergy2(C,S)
[Ea,EDetail] = wenergy2(C,S)
```

Description

For a two-dimensional wavelet decomposition [C,S] (see wavedec2 for details), [Ea,Eh,Ev,Ed] = wenergy2(C,S) returns Ea, which is the percentage of energy corresponding to the approximation, and vectors Eh, Ev, Ed, which contain the percentages of energy corresponding to the horizontal, vertical, and diagonal details, respectively.

[Ea, EDetail] = wenergy2(C,S) returns Ea, and EDetail, which is the sum of vectors Eh, Ev, and Ed.

```
load detail
[C,S] = wavedec2(X,2,'sym4');
[Ea,Eh,Ev,Ed] = wenergy2(C,S)

Ea =
    89.3520

Eh =
    1.8748    2.7360

Ev =
    1.5860    2.6042

Ed =
    0.7539    1.0932
```

```
[Ea,EDetails] = wenergy2(C,S)
Ea =
    89.3520
EDetails =
    4.2147    6.4334
```

wentropy

Entropy (wavelet packet)

Syntax

E = wentropy(X,T,P)
E = wentropy(X,T)
E = wentropy(X,T,0)

Description

E = wentropy(X, T, P) returns the entropy E of the vector or matrix input X. In both cases, output E is a real number.

E = wentropy(X, T) is equivalent to E = wentropy(X, T, 0).

T is a string containing the type of entropy and P is an optional parameter depending on the value of T.

Entropy Type Name (7)	Parameter (P)	Comments
'shannon'		P is not used.
'log energy'		P is not used.
'threshold'	0 ≤ P	P is the threshold.
'sure'	0 ≤ P	P is the threshold.
'norm'	1 ≤ P	P is the power.
'user'	string	P is a string containing the file name of your own entropy function, with a single input X.
FunName	No constraints on P	FunName is any other string except those used for the previous Entropy Type Names listed above.
		FunName contains the file name of your own entropy function, with X as input

Entropy Type Name (T)	Parameter (P)	Comments	
		and P as additional parameter to your entropy function.	

Note The 'user' option is historical and still kept for compatibility, but it is obsoleted by the last option described in the table above. The FunName option do the same as the 'user' option and in addition gives the possibility to pass a parameter to your own entropy function.

Functionals verifying an additive-type property are well suited for efficient searching of binary-tree structures and the fundamental splitting property of the wavelet packets decomposition. Classical entropy-based criteria match these conditions and describe information-related properties for an accurate representation of a given signal. Entropy is a common concept in many fields, mainly in signal processing. The following example lists different entropy criteria. Many others are available and can be easily integrated. In the following expressions, s is the signal and $(s_i)_i$ the coefficients of s in an orthonormal basis.

The entropy E must be an additive cost function such that E(0) = 0 and

$$E(s) = \sum_i E(s_i)$$

· The (nonnormalized) Shannon entropy.

$$E1(s_i) = s_i^2 \log(s_i^2)$$
 so $E1(s) = -\sum_i s_i^2 \log(s_i^2)$

with the convention 0log(0) = 0.

• The concentration in l^p norm entropy with $1 \le p$.

$$E2(s_i) = \left\| s_i \right\|^p \text{ so } E2(s) = \sum_i \left| s_i \right|^p = \left\| s \right\|_p^p$$

• The "log energy" entropy.

$$E3(s_i) = \log(s_i^2) \sum_{so} E3(s) = \sum_{i} \log(s_i^2)$$

with the convention log(0) = 0.

The threshold entropy.

 $E4(s_i) = 1$ if $|s_i| > p$ and 0 elsewhere so $E4(s) = \#\{i \text{ such that } |s_i| > p\}$ is the number of time instants when the signal is greater than a threshold p.

• The "SURE" entropy.

E5(s) = n - #{i such that
$$\left|s_i\right| \le p$$
} + $\sum_i min(s_i^2, p^2)$

For more information, see the section "Wavelet Packets for Compression and Denoising" of the User's Guide.

```
% The current extension mode is zero-padding (see dwtmode).
% Generate initial signal.
x = randn(1,200);
% Compute Shannon entropy of x.
e = wentropy(x, 'shannon')
e =
    -142.7607
% Compute log energy entropy of x.
e = wentropy(x,'log energy')
e =
    -281.8975
% Compute threshold entropy of x
% with threshold equal to 0.2.
e = wentropy(x, 'threshold',0.2)
e =
    162
% Compute Sure entropy of x
% with threshold equal to 3.
e = wentropy(x, 'sure', 3)
```

```
e =
 -0.6575
% Compute norm entropy of x with power equal to 1.1.
e = wentropy(x,'norm',1.1)
 160.1583
% Compute user entropy of x with a user defined
% function: userent for example.
% This function must be a code file, with first line
% of the following form:
%
      function e = userent(x)
% where x is a vector and e is a real number.
% Then a new entropy is defined and can be used typing:
% e = wentropy(x, 'user', 'userent')
% or more directly
% e = wentropy(x, 'userent')
```

wextend

Extend vector or matrix

Syntax

Description

The valid extension types (TYPE) are listed in the table below.

TYPE	Description
1, '1', '1d' or '1D'	1-D extension
2, '2', '2d' or '2D'	2-D extension
'ar' or 'addrow'	Add rows
'ac' or 'addcol'	Add columns

The valid extension modes (MODE) are listed in the table below.

MODE	Description
'zpd'	Zero extension
'sp0'	Smooth extension of order 0
'spd' (or 'sp1')	Smooth extension of order 1
'sym' or 'symh'	Symmetric-padding (half-point): boundary value symmetric replication
'symw'	Symmetric-padding (whole-point): boundary value symmetric replication
'asym' or 'asymh'	Antisymmetric-padding (half-point): boundary value antisymmetric replication
'asymw'	Antisymmetric-padding (whole-point): boundary value antisymmetric replication
'ppd'	Periodized extension (1)

MODE	Description	
'per'	Periodized extension (2):	
	If the signal length is odd, wextend adds an extra sample, equal to the last value, on the right and performs extension using the 'ppd' mode. Otherwise, 'per' reduces to 'ppd'. The same kind of rule stands for images.	

With TYPE = {1, '1', '1d' or '1D'}:

- LOC = 'l' (or 'u') for left (or up) extension.
- LOC = 'r' (or 'd') for right (or down) extension.
- LOC = 'b' for extension on both sides.
- LOC = 'n' null extension.
- The default is LOC = 'b'.
- L is the length of the extension.

With TYPE = { 'ar', 'addrow'}:

- LOC is a 1D extension location.
- The default is LOC = 'b'.
- · L is the number of rows to add.

With TYPE = { 'ac', 'addcol'}:

- LOC is a 1D extension location.
- The default is LOC = 'b'.
- L is the number of columns to add.

With TYPE = $\{2, '2', '2d' \text{ or } '2D'\}$:

- LOC = [LOCROW, LOCCOL] where LOCROW and LOCCOL are 1D extension locations or 'n' (none).
- The default is LOC = 'bb'.
- L = [LROW, LCOL] where LROW is the number of rows to add and LCOL is the number of columns to add.

For more information on symmetric extension modes see "References".

wfbm

Fractional Brownian motion synthesis

Syntax

```
FBM = wfbm(H,L)
FBM = wfbm(H,L,'plot')
FBM = wfbm(H,L,NS,W)
FBM = wfbm(H,L,W,NS)
wfbm(H,L,'plot',NS)
wfbm(H,L,'plot',W)
wfbm(H,L,'plot',NS,W)
wfbm(H,L,'plot',W,NS)
```

Description

FBM = wfbm(H,L) returns a fractional Brownian motion signal FBM of the Hurst parameter H(0 < H < 1) and length L, following the algorithm proposed by Abry and Sellan.

```
FBM = wfbm(H,L,'plot') generates and plots the FBM signal.

FBM = wfbm(H,L,NS,W) or FBM = wfbm(H,L,W,NS) returns the FBM using NS reconstruction steps and the sufficiently regular orthogonal wavelet W.

wfbm(H,L,'plot',NS) or wfbm(H,L,'plot',W) or wfbm(H,L,'plot',NS,W) or wfbm(H,L,'plot',W,NS) generates and plots the FBM signal.

wfbm(H,L) is equivalent to WFBM(H,L,6,'db10').

wfbm(H,L,NS) is equivalent to WFBM(H,L,NS,'db10').
```

A fractional Brownian motion (fBm) is a continuous-time Gaussian process depending on the Hurst parameter 0 < H < 1. It generalizes the ordinary Brownian motion corresponding to H = 0.5 and whose derivative is the white noise. The fBm is self-similar in distribution and the variance of the increments is given by

```
Var(fBm(t)-fBm(s)) = v |t-s|^(2H)
```

where V is a positive constant.

Examples

According to the value of H, the fBm exhibits for H > 0.5, long-range dependence and for H < 0.5, short or intermediate dependence. This example shows each situation using the wfbm file, which generates a sample path of this process.

```
% Generate fBm for H = 0.3 and H = 0.7
% Set the parameter H and the sample length
H = 0.3; lg = 1000;
% Generate and plot wavelet-based fBm for H = 0.3
fBm03 = wfbm(H,lg,'plot');
H = 0.7;
% Generate and plot wavelet-based fBm for H = 0.7
fBm07 = wfbm(H,lg,'plot');
% The last step is equivalent to
% Define wavelet and level of decomposition
% w = ' db10'; ns = 6;
% Generate
% fBm07 = wfbm(H,lg,'plot',w,ns);
```

fBm07 clearly exhibits a stronger low-frequency component and has, locally, less irregular behavior.

More About

Algorithms

Starting from the expression of the fBm process as a fractional integral of the white noise process, the idea of the algorithm is to build a biorthogonal wavelet depending on a given orthogonal one and adapted to the parameter H.

Then the generated sample path is obtained by the reconstruction using the new wavelet starting from a wavelet decomposition at a given level designed as follows: details coefficients are independent random Gaussian realizations and approximation coefficients come from a fractional ARIMA process.

This method was first proposed by Meyer and Sellan and implementation issues were examined by Abry and Sellan.

Nevertheless, the samples generated following this original scheme exhibit too many high-frequency components. To circumvent this undesirable behavior Bardet et al. propose downsampling the obtained sample by a factor 10.

Two internal parameters delta = 10 (the downsampling factor) and a threshold prec = 1E-4, to evaluate series by truncated sums, can be modified by the user for extreme values of H.

A complete overview of long-range dependence process generators is available in Bardet et al.

wfbmesti

wfbmesti

Parameter estimation of fractional Brownian motion

Syntax

HEST = wfbmesti(X)

Description

HEST = Wfbmesti(X) returns a one-by-three vector HEST which contains three estimates of the fractal index H of the input signal X. The signal X is assumed to be a realization of fractional Brownian motion with Hurst index H.

The first two elements of the vector are estimates based on the second derivative with the second computed in the wavelet domain.

The third estimate is based on the linear regression in loglog plot, of the variance of detail versus level.

A fractional Brownian motion (fBm) is a continuous-time Gaussian process depending on the so-called Hurst parameter 0 < H < 1. It generalizes the ordinary Brownian motion corresponding to H = 0.5 and whose derivative is the white noise. The fBm is self-similar in distribution and the variance of the increments is

```
Var(fBm(t)-fBm(s)) = v |t-s|^(2H)
```

where V is a positive constant.

This special form of the variance of the increments suggests various ways to estimate the parameter H. One can find in Bardet et al. a survey of such methods. The wfbmesti file provides three different estimates. The first one, due to Istas and Lang, is based on the discrete second-order derivative. The second one is a wavelet-based adaptation and has similar properties. The third one, proposed by Flandrin, estimates H using the slope of the loglog plot of the detail variance versus the level. A more recent extension can be found in Abry et al.

Examples

Hurst Parameter Estimation

This example shows how to estimate the Hurst index of a fractional Brownian motion. The example simulates 1,000 realizations of fractional Brownian motion with H=0.6. Each realization consists of 10,000 samples. At the end of the simulation, the three estimates of the Hurst index are compared.

Initialize the random number generator for repeatable results. Set the Hurst index equal to 0.6 and the length of the realizations to be 10,000.

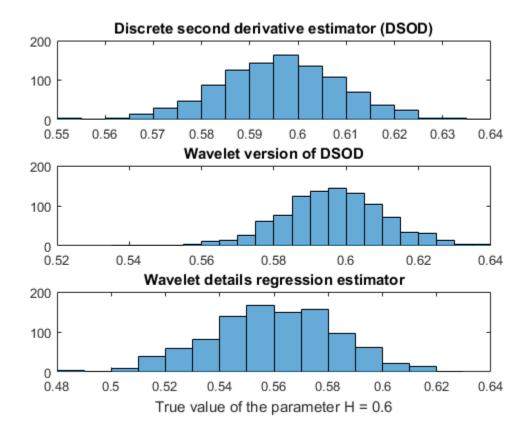

```
rng default;
H = 0.6;
len = 10000;
```

Generate 1,000 realizations of fractional Brownian motion and compute the estimates of the Hurst parameter.

```
n = 1000;
Hest = zeros(n,3);
for ii = 1:n
   fBm06 = wfbm(H,len);
   Hest(ii,:) = wfbmesti(fBm06);
end

Compare the estimates.

subplot(311), histogram(Hest(:,1));
title('Discrete second derivative estimator (DSOD)')
subplot(312), histogram(Hest(:,2));
title('Wavelet version of DSOD')
subplot(313), histogram(Hest(:,3));
title('Wavelet details regression estimator')
xlabel('True value of the parameter H = 0.6')
```

wfilters

Wavelet filters

Syntax

```
[Lo_D,Hi_D,Lo_R,Hi_R] = wfilters('wname')
[F1,F2] = wfilters('wname','type')
```

Description

 $[Lo_D, Hi_D, Lo_R, Hi_R] = wfilters('wname')$ computes four filters associated with the orthogonal or biorthogonal wavelet named in the string 'wname'.

The four output filters are

- · Lo D, the decomposition low-pass filter
- Hi_D, the decomposition high-pass filter
- Lo_R , the reconstruction low-pass filter
- Hi_R, the reconstruction high-pass filter

Available orthogonal or biorthogonal wavelet names 'wname' are listed in the table below.

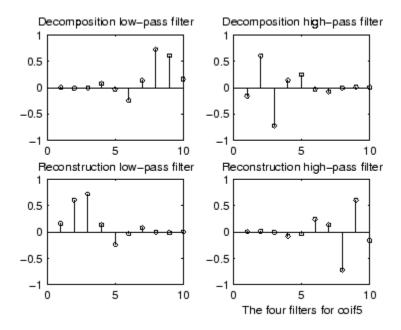

Wavelet Families	Wavelets
Daubechies	'db1' or 'haar', 'db2',, 'db10',, 'db45'
Coiflets	'coif1',,'coif5'
Symlets	'sym2',,'sym8',,'sym45'
Fejer-Korovkin filters	'fk4', 'fk6', 'fk8', 'fk14', 'fk22'
Discrete Meyer	'dmey'
Biorthogonal	'bior1.1', 'bior1.3', 'bior1.5' 'bior2.2', 'bior2.4', 'bior2.6', 'bior2.8'

Wavelet Families	Wavelets
	'bior3.1', 'bior3.3', 'bior3.5', 'bior3.7' 'bior3.9', 'bior4.4', 'bior5.5', 'bior6.8'
Reverse Biorthogonal	'rbio1.1', 'rbio1.3', 'rbio1.5' 'rbio2.2', 'rbio2.4', 'rbio2.6', 'rbio2.8' 'rbio3.1', 'rbio3.3', 'rbio3.5', 'rbio3.7' 'rbio3.9', 'rbio4.4', 'rbio5.5', 'rbio6.8'

[F1,F2] = wfilters('wname', 'type') returns the following filters:

Lo_D and Hi_D	(Decomposition filters)	If 'type' = 'd'
Lo_R and Hi_R	(Reconstruction filters)	If 'type' = 'r'
Lo_D and Lo_R	(Low-pass filters)	If 'type' = '1'
Hi_D and Hi_R	(High-pass filters)	If 'type' = 'h'

```
% Set wavelet name.
wname = 'db5';
% Compute the four filters associated with wavelet name given
% by the input string wname.

wfusimg

Fusion of two images

Syntax

XFUS = wfusimg(X1,X2,WNAME,LEVEL,AFUSMETH,DFUSMETH)
[XFUS,TXFUS,TX1,TX2] = wfusimg(X1,X2,WNAME,LEVEL,AFUSMETH,DFUSMETH)
wfusimg(X1,X2,WNAME,LEVEL,AFUSMETH,DFUSMETH,FLAGPLOT)

Description

The principle of image fusion using wavelets is to merge the wavelet decompositions of the two original images using fusion methods applied to approximations coefficients and details coefficients (see Zeeuw and Misiti et al.).

XFUS = wfusimg(X1,X2,WNAME,LEVEL,AFUSMETH,DFUSMETH) returns the fused image XFUS obtained by fusion of the two original images X1 and X2. Each fusion method, defined by AFUSMETH and DFUSMETH, merges in a specific way detailed below, the decompositions of X1 and X2, at level LEVEL and using wavelet WNAME.

AFUSMETH and DFUSMETH define the fusion method for approximations and details, respectively.

[XFUS,TXFUS,TX1,TX2] = wfusimg(X1,X2,WNAME,LEVEL,AFUSMETH,DFUSMETH) returns, in addition to matrix XFUS, three objects of the class WDECTREE associated with XFUS, X1, and X2 respectively (see @WDECTREE). wfusimg(X1,X2,WNAME,LEVEL,AFUSMETH,DFUSMETH,FLAGPLOT) also plots the objects TXFUS, TX1, and TX2.

Fusmeth denotes AFUSMETH or DFUSMETH. Available fusion methods are

- Simple Fusmeth can be 'max', 'min', 'mean', 'img1', 'img2' or 'rand',
 which merges the two approximations or details structures obtained from X1 and X2
 elementwise by taking the maximum, the minimum, the mean, the first element, the
 second element, or a randomly chosen element
- · Parameter-dependent Fusmeth is of the following form

```
Fusmeth = struct('name',nameMETH,'param',paramMETH)
```

where nameMETH can be

'linear'	
'UD_fusion'	Up-down fusion
'DU_fusion'	Down-up fusion
'RL_fusion'	Right-left fusion
'UserDEF'	User-defined fusion

For the description of these options and the paramMETH parameter, see Wfusmat.

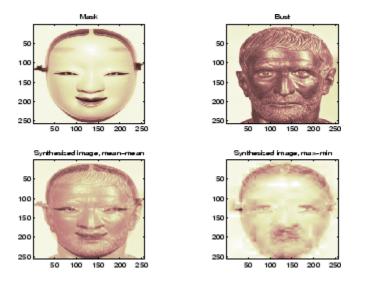

Examples

The following three examples examine the process of image fusion

- The first example merges two different images leading to a new image
- The second example restores an image from two fuzzy versions of an original image.
- The third example shows how to make an image fusion using a user defined fusion method.

```
% Example 1: Fusion of two different images
% Load two original images: a mask and a bust
load mask; X1 = X;
load bust; X2 = X;
% Merge the two images from wavelet decompositions at level 5
% using db2 by taking two different fusion methods
% fusion by taking the mean for both approximations and details
XFUSmean = wfusimg(X1,X2,'db2',5,'mean','mean');
% fusion by taking the maximum for approximations and the
% minimum for the details
XFUSmaxmin = wfusimg(X1,X2,'db2',5,'max','min');
% Plot original and synthesized images
colormap(map);
subplot(221), image(X1), axis square, title('Mask')
subplot(222), image(X2), axis square, title('Bust')
subplot(223), image(XFUSmean), axis square,
```

title('Synthesized image, mean-mean')
subplot(224), image(XFUSmaxmin), axis square,
title('Synthesized image, max-min')

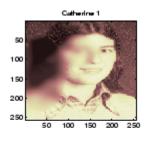

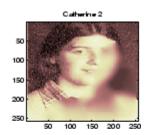

% Example 2: Restoration by fusion of fuzzy images

```
% Load two fuzzy versions of an original image
load cathe_1; X1 = X;
load cathe_2; X2 = X;

% Merge the two images from wavelet decompositions at level 5
% using sym4 by taking the maximum of absolute value of the
% coefficients for both approximations and details
XFUS = wfusimg(X1,X2,'sym4',5,'max','max');

% Plot original and synthesized images
colormap(map);
subplot(221), image(X1), axis square,
title('Catherine 1')
subplot(222), image(X2), axis square,
title('Catherine 2')
subplot(223), image(XFUS), axis square,
title('Synthesized image')
```

```
% The synthesized image is a restored version of good
% quality of the common underlying original image.

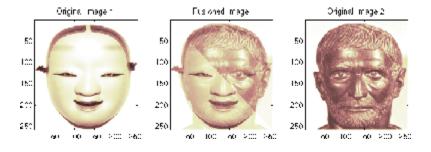

% Example 3: Fusion using a user defined fusion method.
% This example calls a user fusion method defined by the
% file myfus_FUN.m which is listed below at the end of
% the example.

% load two images of the same size.
load mask; A = X;
load bust; B = X;

% Define the fusion method and call the fusion function
Fus_Method = struct('name','userDEF','param','myfus_FUN');
C = wfusmat(A,B,Fus_Method);

figure;
colormap(pink(220))
subplot(1,3,1), image(A), title('Original Image 1'), axis square
```

subplot(1,3,2), image(C), title('Fusioned Image'), axis square subplot(1,3,3), image(B), title('Original Image 2'), axis square

```
%*********
% User defined fusion method. *
%********
function C = myfus_FUN(A,B)

D = logical(triu(ones(size(A)))); t = 0.3;
C = A;
C(D) = t*A(D)+(1-t)*B(D);
C(~D) = t*B(~D)+(1-t)*A(~D);
```

More About

Tips

X1 and X2 must be of same size (see wextend to resize images) and represent indexed images or truecolor images, which are M-by-n matrices or M-by-n-by-3 arrays, respectively.

For more information on image formats, see the image and imfinfo reference pages.

wfusmat | wextend

Introduced before R2006a

wfusmat

Fusion of two matrices or arrayz

Syntax

```
C = wfusmat(A,B,METHOD)
```

Description

C = wfusmat(A,B,METHOD) returns the fused matrix C obtained from the matrices A and B using the fusion method defined by METHOD.

The matrices A and B must be of the same size. The output matrix C is of the same size as A and B.

Available fusion methods are

• Simple, where METHOD is

```
• 'max':D = abs(A) \geq abs(B); C = A(D) + B(\simD)
• 'min':D = abs(A) \leq abs(B); C = A(D) + B(\simD)
```

- 'mean':C = (A+B) / 2; D = ones(size(A))
- 'rand' : $C = A(D) + B(\sim D)$; D is a Boolean random matrix
- 'img1': C = A
- 'img2': C = B
- Parameter-dependent, where METHOD is of the following form:

```
METHOD = struct('name',nameMETH,'param',paramMETH)
```

where nameMETH can be

where 0 £ paramMETH \leq 1

'linear':C = A*paramMETH + B*(1-paramMETH),

• 'UD fusion': Up-down fusion, with paramMETH ≥ 0

```
x = linspace(0,1,size(A,1));
P = x.^paramMETH;
```

Then each row of C is computed with

```
C(i,:) = A(i,:)*(1-P(i)) + B(i,:)*P(i);
So C(1,:) = A(1,:) and C(end,:) = A(end,:)
```

- 'DU fusion': Down-up fusion
- 'LR_fusion': Left-right fusion (columnwise fusion)
- 'RL_fusion': Right-left fusion (columnwise fusion)
- 'UserDEF': User-defined fusion, paramMETH is a string 'userFUNCTION' containing a function name such that C = userFUNCTION(A,B).

In addition, [C,D] = wfusmat(A,B,METHOD) returns the Boolean matrix D when defined, or an empty matrix otherwise.

Introduced before R2006a

wkeep

Keep part of vector or matrix

Syntax

```
Y = wkeep(X,L,OPT)

Y = wkeep(X,L,FIRST)

Y = wkeep(X,L)

Y = wkeep(X,L,'c')

Y = wkeep(X,S,[FIRSTR FIRSTC])
```

Description

wkeep is a general utility.

For a vector, Y = wkeep(X, L, OPT) extracts the vector Y from the vector X. The length of Y is L.

```
If OPT is equal to 'C', 'l', or 'r', Y is the central, left, or right part of X.
```

```
Y = wkeep(X,L,FIRST) returns the vector X(FIRST:FIRST+L-1).
```

```
Y = wkeep(X,L) is equivalent to Y = wkeep(X,L, 'c').
```

For a matrix, Y = wkeep(X,S) extracts the central part of the matrix X. The size of Y is S.

Y = wkeep(X,S,[FIRSTR FIRSTC]) extracts the submatrix of matrix X, of size S and starting from X(FIRSTR,FIRSTC).

Examples

```
% For a vector.
x = 1:10;
y = wkeep(x,6,'c')
y =
```

Introduced before R2006a

wmaxlev

Maximum wavelet decomposition level

Syntax

```
L = wmaxlev(S,'wname')
```

Description

wmaxlev is a one- or two-dimensional wavelet or wavelet packets oriented function.

wmaxlev can help you avoid unreasonable maximum level values. L =
wmaxlev(S, 'wname') returns the maximum level decomposition of signal or image
of size S using the wavelet named in the string 'wname' (see wfilters for more
information).

wmaxlev gives the maximum allowed level decomposition, but in general, a smaller value is taken.

Usual values are 5 for the one-dimensional case, and 3 for the two-dimensional case.

Examples

```
% Compute maximum level decomposition.
1 = wmaxlev(s, w)
1 =
    6
% For a 2-D signal.
s = [2^9 2^7];
w = 'db1';
% Compute maximum level decomposition.
1 = wmaxlev(s,w)
1 =
    7
% which is the same as:
1 = wmaxlev(min(s), w)
1 =
    7
% Change wavelet.
w = 'db7';
% Compute maximum level decomposition.
1 = wmaxlev(s, w)
1 =
    3
```

Introduced before R2006a

wmpalg

Matching pursuit

Syntax

```
YFIT = wmpalg(MPALG,Y,MPDICT)
[YFIT,R] = wmpalg(...)
[YFIT,R,COEFF] = wmpalg(...)
[YFIT,R,COEFF,IOPT] = wmpalg(...)
[YFIT,R,COEFF,IOPT,QUAL] = wmpalg(...)
[YFIT,R,COEFF,IOPT,QUAL,X] = wmpalg(...)
[YFIT,R,COEFF,IOPT,QUAL,X] = wmpalg(...,Name,Value)
```

Description

YFIT = wmpalg(MPALG,Y,MPDICT) returns an adaptive greedy approximation, YFIT, of the input signal, Y, in the dictionary, MPDICT. The adaptive greedy approximation uses the matching pursuit algorithm, MPALG. The dictionary, MPDICT, is typically an overcomplete set of vectors constructed using wmpdictionary.

[YFIT,R] = wmpalg(...) returns the residual, R, which is the difference vector between Y and YFIT at the termination of the matching pursuit.

[YFIT,R,COEFF] = wmpalg(...) returns the expansion coefficients, COEFF. The number of expansion coefficients depends on the number of iterations in the matching pursuit.

[YFIT,R,COEFF,IOPT] = wmpalg(...) returns the column indices of the retained atoms, IOPT. The length of IOPT equals the length of COEFF and is determined by the number of iterations in the matching pursuit.

[YFIT,R,COEFF,IOPT,QUAL] = wmpalg(...) returns the proportion of retained signal energy, QUAL, for each iteration of the matching pursuit. QUAL is the ratio of the ℓ^2 squared norm of the expansion coefficient vector, COEFF, to the ℓ^2 squared norm of the input signal, Y.

[YFIT,R,COEFF,IOPT,QUAL,X] = wmpalg(...) returns the normalized dictionary, X. X contains the unit vectors in the ℓ^2 norm corresponding to the columns of MPDICT.

[YFIT,R,COEFF,IOPT,QUAL,X] = wmpalg(...,Name,Value) returns an adaptive greedy approximation with additional options specified by one or more Name,Value pair arguments.

Input Arguments

MPALG

Matching pursuit algorithm as a string. Valid entries are:

- 'BMP' Basic matching pursuit
- 'OMP' Orthogonal matching pursuit
- 'WMP' Weak orthogonal matching pursuit

See "Matching Pursuit Algorithms".

Default: 'BMP'

MPDICT

Matching pursuit dictionary. MPDICT is a N-by-P matrix where N is equal to the length of the input signal, Y. You can construct MPDICT using wmpdictionary. In matching pursuit, MPDICT is commonly a frame, or overcomplete set of vectors. You may use the Name-Value pair 'lstcpt' to specify a dictionary instead of using MPDICT. If you specify a value for 'lstcpt', wmpalg calls wmpdictionary.

Υ

Signal for matching pursuit. Y is 1-D, real-valued row or column vector. The row dimension of MPDICT must match the length of Y.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

'itermax'

Positive integer fixing the maximum number of iterations of the matching pursuit algorithm. If you do not specify a 'maxerr' value, the number of expansion coefficients, COEFF, the number of dictionary vector indices, IOPT, and the length of the QUAL vector equal the value of 'itermax'.

Default: 25

'1stcpt'

A cell array of cell arrays with valid subdictionaries. This name-value pair is only valid if you do not input a dictionary in MPDICT. Each cell array describes one subdictionary. Valid subdictionaries are:

- A valid Wavelet Toolbox orthogonal or biorthogonal wavelet family short name with the number of vanishing moments and an optional decomposition level and extension mode. For example, { 'sym4',5} denotes the Daubechies least-asymmetric wavelet with 4 vanishing moments at level 5 and the default extension mode 'per'. If you do not specify the optional number level and extension mode, the decomposition level defaults to 5 and the extension mode to 'per'.
- A valid Wavelet Toolbox orthogonal or biorthogonal wavelet family short name preceded by wp with the number of vanishing moments and an optional decomposition level and extension mode. For example, { 'wpsym4',5} denotes the Daubechies least-asymmetric wavelet packet with 4 vanishing moments at level 5. If you do not specify the optional number level and extension mode, the decomposition level defaults to 5 and the extension mode to 'per'.
- · 'dct' Discrete cosine transform-II basis. The DCT-II orthonormal basis is:

$$\phi_k(n) = \begin{cases} \frac{1}{\sqrt{N}} & k = 0\\ \sqrt{\frac{2}{N}} \cos(\frac{\pi}{N}(n + \frac{1}{2})k) & k = 1, 2, \dots, N - 1 \end{cases}$$

• 'sin' Sine subdictionary. The sine subdictionary is:

$$\phi_k(t) = \sin(2\pi kt)$$
 $k = 1, 2, \dots \lceil \frac{N}{2} \rceil$ $0 \le t \le 1$

• 'cos' Cosine subdictionary. The cosine subdictionary is

$$\phi_k(t) = \cos(2\pi kt)$$
 $k = 1, 2, \dots \lceil \frac{N}{2} \rceil$ $0 \le t \le 1$

• 'poly' Polynomial subdictionary. The polynomial subdictionary is:

$$p_n(t) = t^{n-1}$$
 $n = 1, 2, ... 20$ $0 \le t \le 1$

• 'RnIdent' The shifted Kronecker delta subdictionary. The shifted Kronecker delta subdictionary is:

$$\phi_k(n) = \delta(n-k)$$
 $k = 0,1,...N$

If you use the 'lstcpt' name-value pair to generate your dictionary, you can use the additional 'addbeg' and 'addend' name-value pairs to append and addend dictionary atoms. See wmpdictionary for details.

'maxerr'

Cell array containing the name of the norm and the maximum relative error in the norm expressed as a percentage. Valid norms are 'L1', 'L2', and 'Linf'. The relative error expressed as a percentage is

$$100 \frac{\|R\|}{\|Y\|}$$

where R is the residual at each iteration and Y is the input signal. For example, {'L1', 10} sets maximum acceptable ratio of the L1 norms of the residual to the input signal to 0.10.

If you specify 'maxerr', the matching pursuit terminates when the first of the following conditions is satisfied:

- The number of iterations reaches the minimum of the length of the input signal, Y, or 500:
 min(length(Y),500)
- The relative error falls below the percentage you specify with the 'maxerr' name-value pair.

'stepplot'

Number of iterations between successive plots. 'stepplot' requires a positive integer. This name-value pair is only valid when 'typeplot' is 2 or 3 ('movie' or 'stepwise').

'typeplot'

Type of plot to produce during the progression of matching pursuit. Valid entries for 'typeplot' are: 0 or 'none', 1 or 'one', 2 or 'movie', 3 or 'stepwise'. When 'typeplot' is 'movie' or 'stepwise', the plot updates based on the value of 'stepplot'.

Default: 0 or 'none'

'wmpcfs'

Optimality factor for weak orthogonal matching pursuit. The optimality factor is a real number in the interval (0,1]. This name-value pair is only valid when MPALG is 'WMP'.

Default: 0.6

Output Arguments

YFIT

Adaptive greedy approximation of the input signal, Y, in the dictionary

R

Residual after matching pursuit terminates

COEFF

Expansion coefficients in the dictionary. The selected dictionary atoms weighted by the expansion coefficients yield the approximated signal, YFIT.

IOPT

Column indices of the selected dictionary atoms. Using the column indices in IOPT with the expansion coefficients in COEFF, you can form the approximated signal, YFIT.

QUAL

Proportion of retained signal energy for each iteration in the matching pursuit. QUAL is a vector with each element equal to

$$\frac{\mid \mid \alpha_k \mid \mid_2^2}{\mid \mid \mid Y \mid \mid_2^2}$$

where a_k is the vector of expansion coefficients after the k-th iteration.

X

The normalized matching pursuit dictionary. X is an N-by-P matrix where N is the length of the input signal, Y. The columns of X have unit norm.

Examples

Adaptive Approximation using Orthogonal Matching Pursuit

Approximate the cuspamax signal with the dictionary using orthogonal matching pursuit.

Use a dictionary consisting of sym4 wavelet packets and the DCT-II basis.

Return Residual, Expansion Coefficients, Selected Atoms, and Approximation Quality

Obtain the expansion coefficients in the dictionary, the column indices of the selected dictionary atoms, and the proportion of retained signal energy.

Create a dictionary consisting of sym4 wavelet packets and the DCT-II basis. Approximate the cuspamax signal with the dictionary using orthogonal matching pursuit.

```
load cuspamax;
```

Specify the Maximum Number of Iterations

This example shows how to set the maximum number of iterations of the orthogonal matching pursuit to 50.

```
load cuspamax;
lstcpt = {{'wpsym4',1},{'wpsym4',2},'dct'};
mpdict = wmpdictionary(length(cuspamax),'LstCpt',lstcpt);
[yfit,r,coeff,iopt,qual] = wmpalg('OMP',cuspamax,mpdict,...
'itermax',50);
```

Stepwise Plot of Weak Orthogonal Matching Pursuit

This example shows how to allow for a suboptimal choice in the update of the orthogonal matching pursuit.

Relax the requirement to be 0.8 times the optimal assignment. Plot the results stepwise and update the plot every 5 iterations.

```
load cuspamax;
lstcpt = {{'wpsym4',1},{'wpsym4',2},'dct'};
mpdict = wmpdictionary(length(cuspamax),'LstCpt',lstcpt);
[yfit,r,coeff,iopt,qual] = wmpalg('WMP',cuspamax,mpdict,...
'wmpcfs',0.8,'typeplot','stepwise','stepplot',5);
```

Matching Pursuit of Electricity Consumption Data

Obtain a matching pursuit of electricity consumption measured every minute over a 24-hour period.

Load and plot data. The data shows electricity consumption sampled every minute over a 24-hour period. Because the data is centered, the actual usage values are not interpretable.

```
load elec35_nor;
y = signals(32,:);
plot(y); xlabel('Minutes'); ylabel('Usage');
set(gca,'xlim',[1 1440]);
```

Construct a dictionary for matching pursuit consisting of the Daubechies' extremal—phase wavelet with 2 vanishing moments at level 2, the Daubechies' least-asymmetric

wavelet with 4 vanishing moments at levels 1 and 4, the discrete cosine transform-II basis, and the sine basis.

```
dictionary = {{ 'db4',2}, 'dct', 'sin', { 'sym4',1}, { 'sym4',4}};
[mpdict,nbvect] = wmpdictionary(length(y), 'lstcpt', dictionary);
```

Implement orthogonal matching pursuit to obtain a signal approximation in the dictionary. Use 35 iterations. Plot the result.

```
[yfit,r,coef,iopt,qual] = wmpalg('OMP',y,mpdict,'itermax',35);
plot(y); hold on;
plot(yfit,'r'); xlabel('Minutes'); ylabel('Usage');
legend('Original Signal','OMP','Location','NorthEast');
set(gca,'xlim',[1 1440]);
```

Using the expansion coefficients in coef and the atom indices in iopt, construct the signal approximation, yhat, directly from the dictionary. Compare yhat with yfit returned by wmpalg.

```
[~,I] = sort(iopt);
X = mpdict(:,iopt(I));
yhat = X*coef(I);
max(abs(yfit-yhat))
```

Introduced in R2012a

wmpdictionary

Dictionary for matching pursuit

Syntax

```
MPDICT = wmpdictionary(N)
[MPDICT,NBVECT] = wmpdictionary(N)
[MPDICT,NBVECT]= wmpdictionary(N,Name,Value)
[MPDICT,NBVECT,LST] = wmpdictionary(N,Name,Value)
[MPDICT,NBVECT,LST,LONGS] = wmpdictionary(N,Name,Value)
```

Description

MPDICT = wmpdictionary(N) returns the N-by-P dictionary, MPDICT, for the default subdictionaries {{ 'sym4',5}, { 'wpsym4',5}, 'dct', 'sin'}. The column dimension of MPDICT depends on N.

[MPDICT, NBVECT] = wmpdictionary(N) returns the row vector, NBVECT, which contains the number of vectors in each subdictionary. The order of the elements in NBVECT corresponds to the order of the subdictionaries and any prepended or appended subdictionaries. The sum of the elements in NBVECT is the column dimension of MPDICT.

[MPDICT, NBVECT] = wmpdictionary(N, Name, Value) returns the dictionary, MPDICT, using additional options specified by one or more Name, Value pair arguments.

[MPDICT, NBVECT, LST] = wmpdictionary(N, Name, Value) returns the cell array, LST, with descriptions of the subdictionaries.

[MPDICT,NBVECT,LST,LONGS] = wmpdictionary(N,Name,Value) returns the cell array, LONGS, containing the number of vectors in each subdictionary. LONGS is only useful for wavelet subdictionaries. In wavelet subdictionaries, the corresponding element in LONGS gives the number of scaling functions at the coarsest level and wavelet functions by level. See "Visualize Haar Wavelet Dictionary" on page 1-632 for an example using LONGS.

Input Arguments

N

A positive integer equal to the length of your input signal. The dictionary atoms are constructed to have N elements. N equals the row dimension of the dictionary, MPDICT.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

'addbeg'

Prepended subdictionary. The prepended subdictionary is an N-by-M matrix where N is the length of the input signal. wmpdictionary does not check that the M column vectors of the prepended dictionary form a basis. If you do not specify a value for lstcpt, the subdictionary is prepended to the default dictionary. The column vectors in the prepended subdictionary do not have to be unit-norm.

'addend'

Appended subdictionary. The appended subdictionary is a N-by-M matrix where N is the length of the input signal. wmpdictionary does not check that the M column vectors of the prepended dictionary form a basis. If you do not specify a value for lstcpt, the subdictionary is appended to the default dictionary. The column vectors in the appended subdictionary do not have to be unit-norm.

'lstcpt'

A cell array of cell arrays with valid subdictionaries. Each cell array describes one subdictionary. Valid subdictionaries are:

• A valid Wavelet Toolbox orthogonal or biorthogonal wavelet family short name with the number of vanishing moments and an optional decomposition level and extension mode. For example, { 'sym4',5} denotes the Daubechies least-asymmetric wavelet with 4 vanishing moments at level 5 and the default extension mode 'per'. If you do

1-630

not specify the optional level and extension mode, the decomposition level defaults to 5 and the extension mode to 'per'.

- A valid Wavelet Toolbox orthogonal or biorthogonal wavelet family short name preceded by wp with the number of vanishing moments and an optional decomposition level and extension mode. For example, {'wpsym4',5} denotes the Daubechies least-asymmetric wavelet packet with 4 vanishing moments at level 5. If you do not specify the optional level and extension mode, the decomposition level defaults to 5 and the extension mode to 'per'.
- · 'dct' Discrete cosine transform-II basis. The DCT-II orthonormal basis is:

$$\phi_k(n) = \begin{cases} \frac{1}{\sqrt{N}} & k = 0\\ \sqrt{\frac{2}{N}} \cos(\frac{\pi}{N}(n + \frac{1}{2})k) & k = 1, 2, \dots, N - 1 \end{cases}$$

• 'sin' Sine subdictionary. The sine subdictionary is

$$\phi_k(t) = \sin(2\pi kt)$$
 $k = 1, 2, \dots \left\lceil \frac{N}{2} \right\rceil$ $0 \le t \le 1$

where t is a linearly-spaced N-point vector.

• 'cos' Cosine subdictionary. The cosine subdictionary is

$$\phi_k(t) = \cos(2\pi kt)$$
 $k = 1, 2, \dots \left\lceil \frac{N}{2} \right\rceil$ $0 \le t \le 1$

where t is a linearly-spaced N-point vector.

• 'poly' Polynomial subdictionary. The polynomial subdictionary is:

$$p_n(t) = t^{n-1}$$
 $n = 1, 2, ... 20$ $0 \le t \le 1$

where t is a linearly-spaced N-point vector.

 'RnIdent' The shifted Kronecker delta subdictionary. The shifted Kronecker delta subdictionary is:

$$\phi_k(n) = \delta(n-k)$$
 $k = 0,1,...N$

Default: {{ 'sym4',5}, { 'wpsym4',5}, 'dct', 'sin'}

Output Arguments

MPDICT

Matching pursuit dictionary. MPDICT is an N-by-P matrix with the row dimension, N, equal to the length of the input signal. The column dimension of the matrix depends on the size of the concatenated subdictionaries.

NBVECT

Number of vectors in subdictionaries. NBVECT is a row vector containing the number of elements in each subdictionary. The order of the elements in NBVECT corresponds to the order of the subdictionaries and any prepended or appended subdictionaries.

LST

Cell array describing the dictionary. LST is a 1-by-N cell array where N is the number of subdictionaries. Each element of the cell array contains a description of a subdictionary. If you specify a prepended or appended subdictionary, the first element of LST is 'AddBeg' or 'AddEnd'. If you specify a level for the wavelet or wavelet packet, the corresponding element of LST is a 1-by-2 cell array containing the wavelet or wavelet packet name in the first element and the level in the second element.

LONGS

Cell array containing the number of elements for each subdictionary. LONGS is useful only for wavelet subdictionaries. If you specify a wavelet subdictionary, the corresponding element of LONGS provides the number of scaling functions at the coarsest level and the number of wavelets at each level. See "Visualize Haar Wavelet Dictionary" on page 1-632 for an example using LONGS.

Examples

Default Dictionary

Create the default dictionary to represent a signal of length 100.

```
mpdict = wmpdictionary(100);
```

Discrete Cosine Transform and Kronecker Delta Dictionary

Create a DCT and shifted Kronecker delta dictionary to represent a signal of length 100.

```
mpdict = wmpdictionary(100, 'lstcpt', {'dct', 'RnIdent'});
```

Haar Wavelet Packets and Discrete Cosine Transform Dictionary

Create a Haar wavelet packet (level 2) and DCT dictionary. Return the number of atoms in each subdictionary.

```
[mpdict,nbvect] = wmpdictionary(100, 'lstcpt', {{ 'wphaar', 2}, 'dct'});
```

Visualize Haar Wavelet Dictionary

Use the output argument, LONGS, to visualize a dictionary.

Create a Haar wavelet dictionary consisting of level-2 scaling functions and level-1 and level-2 wavelet functions.

```
[mpdict,~,~,longs] = wmpdictionary(100, 'lstcpt', {{ 'haar',2}});
for nn = 1:size(mpdict,2)
    if (nn <= longs{1}(1))</pre>
        plot(mpdict(:,nn),'k','linewidth',2); grid on;
    xlabel('Translation');
        title('Haar Scaling Function - Level 2');
    elseif (nn>longs{1}(1) & nn<= longs{1}(1)+longs{1}(2))</pre>
         plot(mpdict(:,nn),'r','linewidth',2); grid on;
         xlabel('Translation');
        title('Haar Wavelet - Level 2');
    else
        title('Haar Wavelet - Level 1');
        plot(mpdict(:,nn),'b','linewidth',2); grid on;
        title('Haar Wavelet - Level 1');
        xlabel('Translation');
    end
        pause(0.2);
end
```

More About

Matching Pursuit

Matching pursuit refers to a number of greedy or weak-greedy algorithms for computing an adaptive nonlinear expansion of a signal in a *dictionary*. In the majority of matching pursuit applications, a dictionary is an overcomplete set of vectors. The elements of the dictionary are referred to as *atoms* and are typically constructed to have certain time/ frequency or time/scale properties. Matching pursuit takes the NP-hard problem of finding the best nonlinear expansion in a dictionary and implements it in an energy-perserving formulation that guarantees convergence. See "Matching Pursuit Algorithms" for more details.

wavemenu | wmpalg

Introduced in R2012a

wmspca

Multiscale Principal Component Analysis

Syntax

```
[X_SIM,QUAL,NPC,DEC_SIM,PCA_Params] = wmspca(X,LEVEL,WNAME,NPC)
[...] = wmspca(X,LEVEL,WNAME,'mode',EXTMODE,NPC)
[...] = wmspca(DEC,NPC)
[...] = wmspca(X,LEVEL,WNAME,'mode',EXTMODE,NPC)
```

Description

```
[X_SIM,QUAL,NPC,DEC_SIM,PCA_Params] = wmspca(X,LEVEL,WNAME,NPC) or [...] = wmspca(X,LEVEL,WNAME,'mode',EXTMODE,NPC) returns a simplified version X_SIM of the input matrix X obtained from the wavelet-based multiscale principal component analysis (PCA).
```

The input matrix X contains P signals of length N stored columnwise (N > P).

Wavelet Decomposition Parameters

The wavelet decomposition is performed using the decomposition level LEVEL and the wavelet WNAME.

EXTMODE is the extended mode for the DWT (See dwtmode).

If a decomposition DEC obtained using mdwtdec is available, you can use

```
[...] = wmspca(DEC, NPC) instead of
[...] = wmspca(X, LEVEL, WNAME, 'mode', EXTMODE, NPC).
```

Principal Components Parameter: NPC

If NPC is a vector, then it must be of length LEVEL+2. It contains the number of retained principal components for each PCA performed:

- NPC(d) is the number of retained noncentered principal components for details at level d, for 1 <= d <= LEVEL.
- NPC(LEVEL+1) is the number of retained non-centered principal components for approximations at level LEVEL.
- NPC(LEVEL+2) is the number of retained principal components for final PCA after wavelet reconstruction.

NPC must be such that $0 \le NPC(d) \le P$ for $1 \le d \le LEVEL+2$.

If NPC = 'kais' (respectively, 'heur'), then the number of retained principal components is selected automatically using Kaiser's rule (or the heuristic rule).

- Kaiser's rule keeps the components associated with eigenvalues greater the mean of all eigenvalues.
- The heuristic rule keeps the components associated with eigenvalues greater than 0.05 times the sum of all eigenvalues.

If NPC = 'nodet', then the details are "killed" and all the approximations are retained.

Output Parameters

X_SIM is a simplified version of the matrix X.

QUAL is a vector of length P containing the quality of column reconstructions given by the relative mean square errors in percent.

NPC is the vector of selected numbers of retained principal components.

DEC_SIM is the wavelet decomposition of X_SIM

PCA_Params is a structure array of length LEVEL+2 such that:

- $PCA_Params(d).pc$ is a P-by-P matrix of principal components.

The columns are stored in descending order of the variances.

- PCA_Params(d).variances is the principal component variances vector.
- PCA_Params(d).npc = NPC

Examples

Wavelet Principal Component Analysis of Noisy Multivariate Signal

Use wavelet multiscale principal component analysis to denoise a multivariate signal.

Load the dataset consisting of 4 signals of length 1024. Plot the original signals and the signals with additive noise.

```
load ex4mwden;
kp = 0;
for i = 1:4
    subplot(4,2,kp+1), plot(x_orig(:,i)); axis tight;
    title(['Original signal ',num2str(i)])
    subplot(4,2,kp+2), plot(x(:,i)); axis tight;
    title(['Noisy signal ',num2str(i)])
    kp = kp + 2;
end
```

Perform the first multiscale wavelet PCA using the Daubechies' least-asymmetric wavelet with 4 vanishing moments, sym4. Obtain the multiresolution decomposition down to level 5. Use the heuristic rule to decide how many principal components to retain.

```
level = 5;
wname = 'sym4';
npc = 'heur';
[x sim, qual, npc] = wmspca(x,level,wname,npc);
```

Plot the result and examine the quality of the approximation.

```
qual
kp = 0;
for i = 1:4
    subplot(4,2,kp+1), plot(x(:,i)); axis tight;
    title(['Noisy signal ',num2str(i)])
    subplot(4,2,kp+2), plot(x_sim(:,i)); axis tight;
    title(['First PCA ',num2str(i)])
    kp = kp + 2;
end
```

The quality results are all close to 100%. The npc vector gives the number of principal components retained at each level.

Suppress the noise by removing the principal components at levels 1–3. Perform the multiscale PCA again.

```
npc(1:3) = zeros(1,3);
[x_sim, qual, npc] = wmspca(x,level,wname,npc);

Plot the result.

kp = 0;
for i = 1:4
    subplot(4,2,kp+1), plot(x(:,i)); axis tight;
    title(['Noisy signal ',num2str(i)])
    subplot(4,2,kp+2), plot(x_sim(:,i)); axis tight;
    title(['Second PCA ',num2str(i)])
    kp = kp + 2;
end
```

More About

Algorithms

The multiscale principal components generalizes the usual PCA of a multivariate signal seen as a matrix by performing simultaneously a PCA on the matrices of details of different levels. In addition, a PCA is performed also on the coarser approximation coefficients matrix in the wavelet domain as well as on the final reconstructed matrix. By selecting conveniently the numbers of retained principal components, interesting simplified signals can be reconstructed.

wmulden

Introduced in R2006b

wmulden

Wavelet multivariate de-noising

Syntax

```
[X_DEN,NPC,NESTCOV,DEC_DEN,PCA_Params,DEN_Params] = ...
wmulden(X,LEVEL,WNAME,NPC_APP,NPC_FIN,TPTR,SORH)
[...] = wmulden(X,LEVEL,WNAME,'mode',EXTMODE,NPC_APP,...)
[...] = wmulden(DEC,NPC_APP)
[...] = wmulden(X,LEVEL,WNAME,'mode',EXTMODE,NPC_APP)
[DEC,PCA_Params] = wmulden('estimate',DEC,NPC_APP,NPC_FIN)
[X_DEN,NPC,DEC_DEN,PCA_Params] = wmulden('execute',DEC,PC_Params)
```

Description

```
[X_DEN,NPC,NESTCOV,DEC_DEN,PCA_Params,DEN_Params] = ... wmulden(X,LEVEL,WNAME,NPC_APP,NPC_FIN,TPTR,SORH) or [...] = wmulden(X,LEVEL,WNAME,'mode',EXTMODE,NPC_APP,...) returns a denoised version X_DEN of the input matrix X. The strategy combines univariate wavelet de-noising in the basis where the estimated noise covariance matrix is diagonal with noncentered Principal Component Analysis (PCA) on approximations in the wavelet domain or with final PCA.
```

The input matrix X contains P signals of length N stored columnwise where N > P.

Wavelet Decomposition Parameters

The wavelet decomposition is performed using the decomposition level LEVEL and the wavelet WNAME.

EXTMODE is the extended mode for the DWT (See dwtmode).

If a decomposition $\ensuremath{\mathsf{DEC}}$ obtained using $\ensuremath{\mathsf{mdwtdec}}$ is available, you can use

```
[...] = wmulden(DEC,NPC_APP) instead of
```

```
[...] = wmulden(X,LEVEL,WNAME, 'mode',EXTMODE,NPC_APP).
```

Principal Components Parameters: NPC_APP and NPC_FIN

The input selection methods NPC_APP and NPC_FIN define the way to select principal components for approximations at level LEVEL in the wavelet domain and for final PCA after wavelet reconstruction, respectively.

If NPC_APP (or NPC_FIN) is an integer, it contains the number of retained principal components for approximations at level LEVEL (or for final PCA after wavelet reconstruction).

```
NPC XXX must be such that 0 <= NPC XXX <= P
```

NPC_APP or NPC_FIN = 'kais' or 'heur' selects the number of retained principal components using Kaiser's rule or the heuristic rule automatically.

- Kaiser's rule keeps the components associated with eigenvalues greater than the mean of all eigenvalues.
- The heuristic rule keeps the components associated with eigenvalues greater than 0.05 times the sum of all eigenvalues.

NPC_APP or NPC_FIN = 'none' is equivalent to NPC_APP or NPC_FIN = P.

De-noising Parameters: TPTR and SORH

The default values for the de-noising parameters TPTR and SORH are:

```
TPTR = 'sqtwolog' and SORH = 's'
```

Valid values for TPTR are

```
'rigsure', 'heursure', 'sqtwolog', 'minimaxi',
'penalhi', 'penalme', 'penallo'
```

Valid values for SORH are:

```
's' (soft) or 'h' (hard)
```

For additional information, see wden and wbmpen.

Output Parameters

X_DEN is a de-noised version of the input matrix X.

NPC is the vector of selected numbers of retained principal components.

NESTCOV is the estimated noise covariance matrix obtained using the minimum covariance determinant (MCD) estimator.

DEC_DEN is the wavelet decomposition of X_DEN.

PCA Params is a structure such that:

```
PCA_Params.NEST = {pc_NEST,var_NEST,NESTCOV}
PCA_Params.APP = {pc_APP,var_APP,npc_APP}
PCA_Params.FIN = {pc_FIN,var_FIN,npc_FIN}
```

where:

pc_XXX is a P-by-P matrix of principal components.

The columns are stored in descending order of the variances.

- var_XXX is the principal component variances vector.
- NESTCOV is the covariance matrix estimate for detail at level 1.

DEN_Params is a structure such that:

- DEN_Params.thrVAL is a vector of length LEVEL which contains the threshold values for each level.
- DEN_Params.thrMETH is a string containing the name of the de-noising method (TPTR).
- DEN_Params.thrTYPE is a character variable containing the type of the thresholding (SORH).

Special Cases

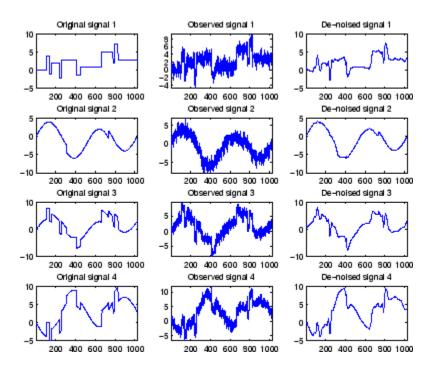

[DEC,PCA_Params] = wmulden('estimate',DEC,NPC_APP,NPC_FIN) returns the wavelet decomposition DEC and the Principal Components Estimates PCA_Params.

[X_DEN,NPC,DEC_DEN,PCA_Params] = wmulden('execute',DEC,PC_Params) uses the principal components estimates PCA Params previously computed.

The input value DEC can be replaced by X, LEVEL, and WNAME.

Examples

```
% Load a multivariate signal x together with
% the original signals (x orig) and true noise
% covariance matrix (covar).
load ex4mwden
% Set the de-noising method parameters.
level = 5;
wname = 'sym4';
tptr = 'sqtwolog';
sorh = 's';
% Set the PCA parameters to select the number of
% retained principal components automatically by
% Kaiser's rule.
npc app = 'kais';
npc fin = 'kais';
% Perform multivariate de-noising.
[x_den, npc, nestco] = wmulden(x, level, wname, npc_app, ...
                                   npc fin, tptr, sorh);
% Display the original and de-noised signals.
kp = 0;
for i = 1:4
    subplot(4,3,kp+1), plot(x orig(:,i));
    title(['Original signal ',num2str(i)])
    subplot(4,3,kp+2), plot(x(:,i));
    title(['Observed signal ',num2str(i)])
    subplot(4,3,kp+3), plot(x_den(:,i));
    title(['De-noised signal ',num2str(i)])
    kp = kp + 3;
end
```

% The results are good: the first function, which is % irregular, is correctly recovered while the second % function, more regular, is well de-noised.

% The second output argument gives the numbers % of retained principal components for PCA for % approximations and for final PCA.

npc

npc =

2 2

% The third output argument contains the estimated % noise covariance matrix using the MCD based % on the matrix of finest details.

wnoise

Noisy wavelet test data

Syntax

```
X = wnoise(FUN,N)
[X,XN] = wnoise(FUN,N,SQRT_SNR)
[X,XN] = wnoise(FUN,N,SQRT_SNR,INIT)
```

Description

X = wnoise(FUN,N) returns values of the test signal given by FUN, on a 2^N grid of [0,1].

[X,XN] = wnoise(FUN,N,SQRT_SNR) returns a test vector X as above, rescaled such that $std(X) = SQRT_SNR$. The returned vector XN contains the same test vector corrupted by additive Gaussian white noise N(0,1). Then, XN has a signal-to-noise ratio of $SNR = (SQRT_SNR)^2$.

[X,XN] = wnoise(FUN,N,SQRT_SNR,INIT) returns previous vectors X and XN, but the generator seed is set to INIT value.

The six functions below are due to Donoho and Johnstone (See "References").

FUN = 1	or	'blocks'
FUN = 2	or	'bumps'
FUN = 3	or	'heavy sine'
FUN = 4	or	'doppler'
FUN = 5	or	'quadchirp'
FUN = 6	or	'mishmash'

```
% Generate 2^10 samples of 'Heavy sine' (item 3). x = wnoise(3,10);
```

```
% Generate 2^10 samples of 'Doppler' (item 4) and of
% noisy 'Doppler' with a square root of signal-to-noise
% ratio equal to 7.
[x,noisyx] = wnoise(4,10,7);
% To introduce your own rand seed, a fourth
% argument is allowed:
init = 2055415866;
[x,noisyx] = wnoise(4,10,7,init);
% Plot all the test functions.
ind = linspace(0,1,2^10);
for i = 1:6
    x = wnoise(i,10);
    subplot(6,1,i), plot(ind,x)
end

wden

wnoisest

Estimate noise of 1-D wavelet coefficients

Syntax

```
STDC = wnoisest(C,L,S)
STDC = wnoisest(C)
STDC = wnoisest(C)
```

Description

STDC = wnoisest(C,L,S) returns estimates of the detail coefficients' standard deviation for levels contained in the input vector S. [C,L] is the input wavelet decomposition structure (see wavedec for more information).

If C is a one dimensional cell array, STDC = wnoisest(C) returns a vector such that STDC(k) is an estimate of the standard deviation of $C\{k\}$.

If C is a numeric array, STDC = wnoisest(C) returns a vector such that STDC(k) is an estimate of the standard deviation of C(k,:).

The estimator used is Median Absolute Deviation / 0.6745, well suited for zero mean Gaussian white noise in the de-noising one-dimensional model (see thselect for more information).

Examples

Estimate Noise Standard Deviation in The Presence of Outliers

Estimate of the noise standard deviation in an N(0,1) white Gaussian noise vector with outliers.

Create an N(0,1) noise vector with 10 randomly-placed outliers.

```
rng default;
x = randn(1000,1);
```

```
P = randperm(length(x));
indices = P(1:10);
x(indices(1:5)) = 10;
x(indices(6:end)) = -10;
```

Obtain the discrete wavelet transform down to level 2 using the Daubechies' extremal phase wavelet with 3 vanishing moments.

```
[c,1] = wavedec(x,2,'db3');
stdc = wnoisest(c,1,1:2)
```

In spite of the outliers, wnoisest provides a robust estimate of the standard deviation.

wpbmpen

Penalized threshold for wavelet packet de-noising

Syntax

```
THR = wpbmpen(T,SIGMA,ALPHA)
wpbmpen(T,SIGMA,ALPHA,ARG)
```

Description

THR = wpbmpen(T,SIGMA,ALPHA) returns a global threshold THR for de-noising. THR is obtained by a wavelet packet coefficients selection rule using a penalization method provided by Birge-Massart.

T is a wavelet packet tree corresponding to the wavelet packet decomposition of the signal or image to be de-noised.

SIGMA is the standard deviation of the zero mean Gaussian white noise in the de-noising model (see wnoisest for more information).

ALPHA is a tuning parameter for the penalty term. It must be a real number greater than 1. The sparsity of the wavelet packet representation of the de-noised signal or image grows with ALPHA. Typically ALPHA = 2.

THR minimizes the penalized criterion given by

let t* be the minimizer of

```
crit(t) = -sum(c(k)^2, k \le t) + 2*SIGMA^2*t*(ALPHA + log(n/t))
```

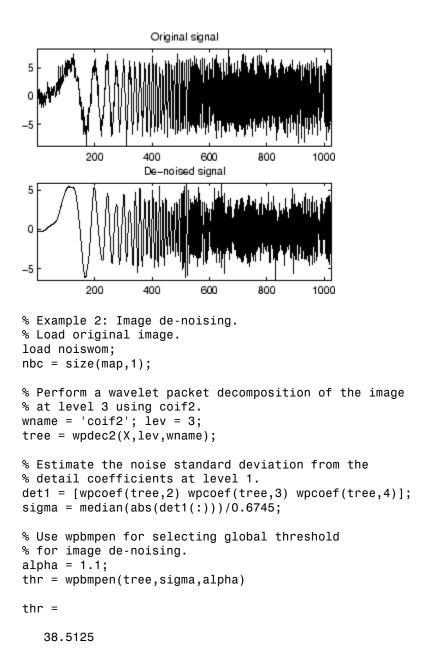

where c(k) are the wavelet packet coefficients sorted in decreasing order of their absolute value and n is the number of coefficients, then $THR = |c(t^*)|$.

wpbmpen(T,SIGMA,ALPHA,ARG) computes the global threshold and, in addition, plots three curves:

```
• 2*SIGMA^2*t*(ALPHA + log(n/t))
```

```
sum(c(k)^2,k£t)crit(t)
```

```
% Example 1: Signal de-noising.

wpdec

Wavelet packet decomposition 1-D

Syntax

```
T = wpdec(X,N,'wname',E,P)
T = wpdec(X,N,'wname')
T = wpdec(X,N,'wname','shannon')
T
```

Description

wpdec is a one-dimensional wavelet packet analysis function.

T = wpdec(X,N,'wname',E,P) returns a wavelet packet tree T corresponding to the wavelet packet decomposition of the vector X at level N, with a particular wavelet ('wname', see wfilters for more information).

```
T = wpdec(X, N, 'wname') is equivalent to T = wpdec(X, N, 'wname', 'shannon').
```

E is a string containing the type of entropy and *P* is an optional parameter depending on the value of T (see wentropy for more information).

Entropy Type Name (E)	Parameter (P)	Comments
'shannon'		P is not used.
'log energy'		P is not used.
'threshold'	0 ≤ P	P is the threshold.
'sure'	0 ≤ P	P is the threshold.
'norm'	1 ≤ P	P is the power.
'user'	string	P is a string containing the file name of your own entropy function, with a single input X.

Entropy Type Name (E)	Parameter (P)	Comments
FunName	No constraints on P	FunName is any other string except those used for the previous Entropy Type Names listed above. FunName contains the file name of your own entropy function, with X as input and P as additional parameter to your entropy function.

Note The 'user' option is historical and still kept for compatibility, but it is obsoleted by the last option described in the table above. The FunName option do the same as the 'user' option and in addition gives the possibility to pass a parameter to your own entropy function.

The wavelet packet method is a generalization of wavelet decomposition that offers a richer signal analysis. Wavelet packet atoms are waveforms indexed by three naturally interpreted parameters: position and scale as in wavelet decomposition, and frequency.

For a given orthogonal wavelet function, a library of wavelet packets bases is generated. Each of these bases offers a particular way of coding signals, preserving global energy and reconstructing exact features. The wavelet packets can then be used for numerous expansions of a given signal.

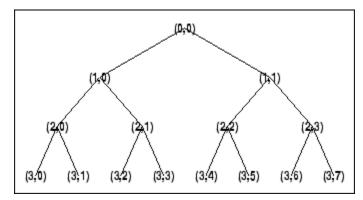

Simple and efficient algorithms exist for both wavelet packets decomposition and optimal decomposition selection. Adaptive filtering algorithms with direct applications in optimal signal coding and data compression can then be produced.

In the orthogonal wavelet decomposition procedure, the generic step splits the approximation coefficients into two parts. After splitting we obtain a vector of approximation coefficients and a vector of detail coefficients, both at a coarser scale. The information lost between two successive approximations is captured in the detail coefficients. The next step consists in splitting the new approximation coefficient vector; successive details are never re-analyzed.

In the corresponding wavelet packets situation, each detail coefficient vector is also decomposed into two parts using the same approach as in approximation vector splitting. This offers the richest analysis: the complete binary tree is produced in the one-dimensional case or a quaternary tree in the two-dimensional case.

Examples

```
% The current extension mode is zero-padding (see dwtmode).
% Load signal.
load noisdopp; x = noisdopp;
% Decompose x at depth 3 with db1 wavelet packets
% using Shannon entropy.
wpt = wpdec(x,3,'db1','shannon');
% The result is the wavelet packet tree wpt.
% Plot wavelet packet tree (binary tree, or tree of order 2).
plot(wpt)
```

More About

Algorithms

The algorithm used for the wavelet packets decomposition follows the same line as the wavelet decomposition process (see dwt and wavedec for more information).

wpdec2

Wavelet packet decomposition 2-D

Syntax

```
T = wpdec2(X,N,'wname',E,P)
T = wpdec2(X,N,'wname')
T = wpdec2(X,N,wnam,'shannon')
```

Description

wpdec2 is a two-dimensional wavelet packet analysis function.

T = wpdec2(X,N,'wname',E,P) returns a wavelet packet tree T corresponding to the wavelet packet decomposition of the matrix X, at level N, with a particular wavelet ('wname', see wfilters for more information).

```
T = wpdec2(X,N,'wname') is equivalent to T = wpdec2(X,N,wnam, 'shannon').
```

E is a string containing the type of entropy and P is an optional parameter depending on the value of T (see wentropy for more information).

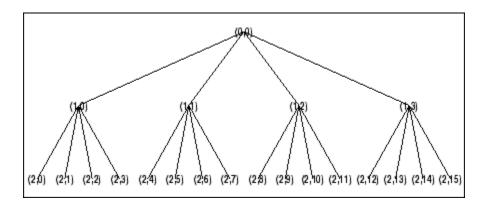

Entropy Type Name (E)	Parameter (P)	Comments
'shannon'		P is not used.
'log energy'		P is not used.
'threshold'	0 ≤ P	P is the threshold.
'sure'	0 ≤ P	P is the threshold.
'norm'	1 ≤ P	P is the power.
'user'	string	P is a string containing the file name of your own entropy function, with a single input X.
STR	No constraints on P	STR is any other string except those used for the previous Entropy Type Names listed above.

Entropy Type Name (E)	Parameter (P)	Comments
		STR contains the file name of your
		own entropy function, with X as input
		and P as additional parameter to your
		entropy function.

Note The 'user' option is historical and still kept for compatibility, but it is obsoleted by the last option described in the preceding table. The FunName option does the same as the 'user' option and in addition, allows you to pass a parameter to your own entropy function.

See wpdec for a more complete description of the wavelet packet decomposition.

```
% The current extension mode is zero-padding (see dwtmode).
% Load image.
load tire
% X contains the loaded image.
% For an image the decomposition is performed using:
t = wpdec2(X,2,'db1');
% The default entropy is shannon.
% Plot wavelet packet tree
% (quarternary tree, or tree of order 4).
plot(t)
```

More About

Tips

When X represents an indexed image, X is an m-by-n matrix. When X represents a truecolor image, it is an m-by-n-by-3 array, where each m-by-n matrix represents a red, green, or blue color plane concatenated along the third dimension.

For more information on image formats, see the image and imfinfo reference pages.

Algorithms

The algorithm used for the wavelet packets decomposition follows the same line as the wavelet decomposition process (see dwt2 and wavedec2 for more information).

wpdencmp

De-noising or compression using wavelet packets

Syntax

```
[XD,TREED,PERF0,PERFL2] =
wpdencmp(X,SORH,N,'wname',CRIT,PAR,KEEPAPP)
[XD,TREED,PERF0,PERFL2] = wpdencmp(TREE,SORH,CRIT,PAR,KEEPAPP)
```

Description

wpdencmp is a one- or two-dimensional de-noising and compression oriented function.

wpdencmp performs a de-noising or compression process of a signal or an image, using wavelet packet. The ideas and the procedures for de-noising and compression using wavelet packet decomposition are the same as those used in the wavelets framework (see wden and wdencmp for more information).

```
[XD,TREED,PERFO,PERFL2] = wpdencmp(X,SORH,N,'wname',CRIT,PAR,KEEPAPP) returns a de-noised or compressed version XD of input signal X (one- or two-dimensional) obtained by wavelet packets coefficients thresholding.
```

The additional output argument TREED is the wavelet packet best tree decomposition (see besttree for more information) of XD. PERFL2 and PERFO are L^2 energy recovery and compression scores in percentages.

PERFL2 = 100 * (vector-norm of WP-cfs of XD / vector-norm of WP-cfs of X^2 .

If X is a one-dimensional signal and 'wname' an orthogonal wavelet, PERFL2 is reduced to

$$\frac{100\left\|XD\right\|^2}{\left\|X\right\|^2}$$

SORH equal to 's' or 'h' is for soft or hard thresholding (see wthresh for more information).

Wavelet packet decomposition is performed at level N and 'wname' is a string containing the wavelet name. Best decomposition is performed using entropy criterion defined by string CRIT and parameter PAR (see wentropy for more information). Threshold parameter is also PAR. If KEEPAPP = 1, approximation coefficients cannot be thresholded; otherwise, they can be.

[XD, TREED, PERFO, PERFL2] = wpdencmp(TREE, SORH, CRIT, PAR, KEEPAPP) has the same output arguments, using the same options as above, but obtained directly from the input wavelet packet tree decomposition TREE (see wpdec for more information) of the signal to be de-noised or compressed.

In addition if CRIT = 'nobest' no optimization is done and the current decomposition is thresholded.

```
[xc,wpt,perf0,perf12] = ...

wpfun

Wavelet packet functions

Syntax

```
[WPWS,X] = wpfun('wname',NUM,PREC)
[WPWS,X] = wpfun('wname',NUM)
[WPWS,X] = wpfun('wname',NUM,7)
```

Description

wpfun is a wavelet packet analysis function.

[WPWS,X] = wpfun('wname', NUM, PREC) computes the wavelet packets for a wavelet 'wname' (see wfilters for more information), on dyadic intervals of length 2^{-PREC}.

PREC must be a positive integer. Output matrix WPWS contains the W functions of index from 0 to NUM, stored row-wise as [W_0 ; W_1 ; ...; W_{NUM}]. Output vector X is the corresponding common X-grid vector.

```
[WPWS,X] = wpfun('wname', NUM) is equivalent to
[WPWS,X] = wpfun('wname', NUM,7).
```

The computation scheme for wavelet packets generation is easy when using an orthogonal wavelet. We start with the two filters of length 2N, denoted h(n) and g(n), corresponding to the wavelet.

Now by induction let us define the following sequence of functions $(W_n(x), n = 0, 1, 2, ...)$ by

$$\begin{split} W_{2n}(x) &= \sqrt{2} \sum_{k=0,...,2N-1} h(k) W_n(2x-k) \\ W_{2n+1}(x) &= \sqrt{2} \sum_{k=0,...,2N-1} g(k) W_n(2x-k) \end{split}$$

where $W_0(x) = \phi(x)$ is the scaling function and $W_1(x) = \psi(x)$ is the wavelet function.

For example for the Haar wavelet we have

$$N = 1, h(0) = h(1) = \frac{1}{\sqrt{2}}$$

and

$$g(0) = -g(1) = \frac{1}{\sqrt{2}}$$

The equations become

$$W_{2n}(x) = W_n(2x) + W_n(2x-1)$$

and

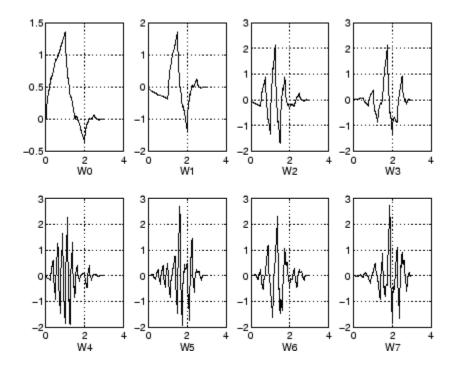

$$(W_{2n+1}(x) = W_n(2x) - W_n(2x-1))$$

 $W_0(x) = \phi(x)$ is the haar scaling function and $W_1(x) = \psi(x)$ is the haar wavelet, both supported in [0,1].

Then we can obtain W_{2n} by adding two 1/2-scaled versions of W_n with distinct supports [0,1/2] and [1/2,1], and obtain W_{2n+1} by subtracting the same versions of W_n .

Starting from more regular original wavelets, using a similar construction, we obtain smoothed versions of this system of W-functions, all with support in the interval [0, 2N-1].

```
% Compute the db2 Wn functions for n = 0 to 7, generating
% the db2 wavelet packets.
[wp,x] = wpfun('db2',7);
% Using some plotting commands,
% the following figure is generated.
```

wpjoin

Recompose wavelet packet

Syntax

```
T = wpjoin(T,N)
[T,X] = wpjoin(T,N)
T = wpjoin(T)
T = wpjoin(T,0)
[T,X] = wpjoin(T)
[T,X] = wpjoin(T,0)
```

Description

wpjoin is a one- or two-dimensional wavelet packet analysis function.

wpjoin updates the wavelet packet tree after the recomposition of a node.

The nodes are numbered from left to right and from top to bottom. The root index is 0.

T = wpjoin(T, N) returns the modified wavelet packet tree T corresponding to a recomposition of the node N.

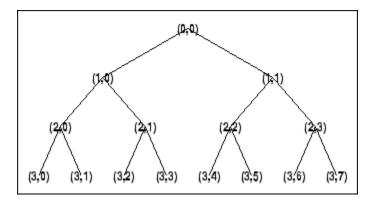

```
[T,X] = wpjoin(T,N) also returns the coefficients of the node.

T = wpjoin(T) is equivalent to T = wpjoin(T,0).

[T,X] = wpjoin(T) is equivalent to [T,X] = wpjoin(T,0).
```

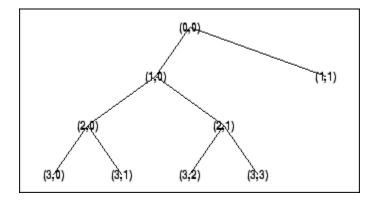

```
% The current extension mode is zero-padding (see dwtmode).
% Load signal.
load noisdopp; x = noisdopp;
% Decompose x at depth 3 with db1 wavelet packets.
```

```
wpt = wpdec(x,3,'db1');
% Plot wavelet packet tree wpt.
plot(wpt)
```

% Recompose packet (1,1) or 2
wpt = wpjoin(wpt,[1 1]);

% Plot wavelet packet tree wpt.
plot(wpt)

wprcoef

Reconstruct wavelet packet coefficients

Syntax

```
X = wprcoef(T,N)
X = wprcoef(T)
X = wprcoef(T,0)
```

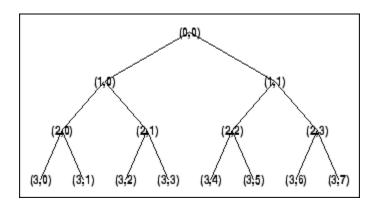

Description

wprcoef is a one- or two-dimensional wavelet packet analysis function.

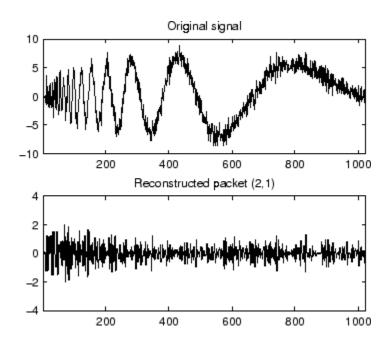

X = wprcoef(T, N) computes reconstructed coefficients of the node N of the wavelet packet tree T.

```
X = wprcoef(T) is equivalent to X = wprcoef(T, 0).
```

```
% The current extension mode is zero-padding (see dwtmode)
% Load signal.
load noisdopp; x = noisdopp;
figure(1); subplot(211);
plot(x); title('Original signal');
% Decompose x at depth 3 with db1 wavelet packets
% using Shannon entropy.
t = wpdec(x,3,'db1','shannon');
% Plot wavelet packet tree.
plot(t)
```

```
% Reconstruct packet (2,1).
rcfs = wprcoef(t,[2 1]);
figure(1); subplot(212);
plot(rcfs); title('Reconstructed packet (2,1)');

wpspectrum

Wavelet packet spectrum

Syntax

```
[SPEC,TIMES,FREQ] = wpspectrum(WPT,Fs)
[...] = wpspectrum(WPT,Fs,'plot')
[...,TNFO] = wpspectrum(...)
```

Description

[SPEC,TIMES,FREQ] = wpspectrum(WPT,Fs) returns a matrix of wavelet packet spectrum estimates, SPEC, for the binary wavelet packet tree object, WPT. Fs is the sampling frequency in Hertz. SPEC is a 2^J -by-N matrix where J is the level of the wavelet packet transform and N is the length of the time series. TIMES is a 1-by-N vector of times and FREQ is a 1-by- 2^J vector of frequencies.

```
[...] = wpspectrum(WPT,Fs,'plot') displays the wavelet packet spectrum.
```

[..., TNFO] = wpspectrum(...) returns the terminal nodes of the wavelet packet tree in frequency order.

Input Arguments

WPT

WPT is a binary wavelet packet tree of class wptree.

Fs

Sampling frequency in Hertz as a scalar of class double.

Default: 1

plot

The string 'plot' displays the wavelet packet spectrum. Enter 'plot' after Fs to produce a plot of the wavelet packet spectrum.

Output Arguments

SPEC

Wavelet packet spectrum. SPEC is a 2^{J} -by-N matrix where J is the level of the wavelet packet transform and N is the length of node 0 in the wavelet packet tree object.

The frequency spacing between the rows of SPEC is $Fs/2^{J+1}$.

TIMES

Time vector. TIMES is a vector of times in seconds equal in length to node 0 of the wavelet packet tree object. The time spacing between elements is 1/Fs.

FREQ

Frequency vector. FREQ is a vector of frequencies of length 2^J where J is the level of the wavelet packet tree object. The frequency spacing in FREQ is $Fs/2^{J+1}$.

TNF0

Terminal nodes. TNFO is a vector of the terminal nodes of the wavelet packet tree object in frequency order.

Examples

Wavelet packet spectrum for signal consisting of two sinusoids with disjoint support:

```
fs = 500;
t = 0:1/fs:4;
y = sin(32*pi*t).*(t<2) + sin(128*pi*t).*(t>=2);
subplot(2,1,1);
plot(t,y);
axis tight
title('Analyzed Signal');
```

```
% Wavelet packet spectrum
level = 6;
wpt = wpdec(y,level,'sym6');
subplot(2,1,2);
[S,T,F] = wpspectrum(wpt,fs,'plot');
Wavelet packet spectrum of chirp:
fs = 1000;
t = 0:1/fs:2;
% create chirp signal
y = \sin(256*pi*t.^2);
% Plot the analyzed signal
subplot(2,1,1);
plot(t,y);
axis tight
title('Analyzed Signal');
% Wavelet packet spectrum
level = 6;
wpt = wpdec(y,level,'sym8');
subplot(2,1,2);
[S,T,F] = wpspectrum(wpt,fs,'plot');
```

More About

Wavelet Packet Spectrum

The wavelet packet spectrum contains the absolute values of the coefficients from the frequency-ordered terminal nodes of the input binary wavelet packet tree. The terminal nodes provide the finest level of frequency resolution in the wavelet packet transform. If J denotes the level of the wavelet packet transform and Fs is the sampling frequency, the terminal nodes approximate bandpass filters of the form:

$$[\frac{nFs}{2^{J+1}},\frac{(n+1)Fs}{2^{J+1}}) \quad n=0,1,2,3,\dots 2^{J}-1$$

At the terminal level of the wavelet packet tree, the transform divides the interval from 0 to the Nyquist frequency into bands of approximate width $Fs/2^{J+1}$.

Algorithms

wpspectrum computes the wavelet packet spectrum as follows:

- Extract the wavelet packet coefficients corresponding to the terminal nodes. Take the
 absolute value of the coefficients.
- Order the wavelet packet coefficients by frequency ordering.
- Determine the time extent on the original time axis corresponding to each wavelet packet coefficient. Repeat each wavelet packet coefficient to fill in the time gaps between neighboring wavelet packet coefficients and create a vector equal in length to node 0 of the wavelet packet tree object.
- "Wavelet Packet Spectrum"

wpsplt

Split (decompose) wavelet packet

Syntax

```
T = wpsplt(T,N)
[T,cA,cD] = wpsplt(T,N)
[T,cA,cH,cV,cD] = wpsplt(T,N)
```

Description

wpsplt is a one- or two-dimensional wavelet packet analysis function.

wpsplt updates the wavelet packet tree after the decomposition of a node.

T = wpsplt(T, N) returns the modified wavelet packet tree T corresponding to the decomposition of the node N.

For a one-dimensional decomposition,

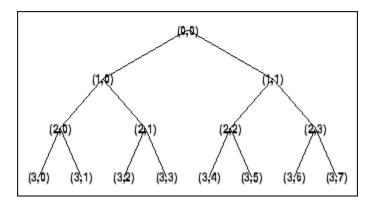

```
[T, cA, cD] = wpsplt(T, N) with cA = approximation and cD = detail of node N.
```

For a two-dimensional decomposition,

[T,cA,cH,cV,cD] = wpsplt(T,N) with cA = approximation and cH,cV,c = horizontal, vertical, and diagonal details of node N.

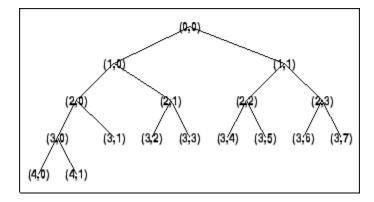

```
% The current extension mode is zero-padding (see dwtmode).
% Load signal.
load noisdopp;
x = noisdopp;
% Decompose x at depth 3 with db1 wavelet packets.
wpt = wpdec(x,3,'db1');
```

% Plot wavelet packet tree wpt.
plot(wpt)

```
% Decompose packet (3,0).
wpt = wpsplt(wpt,[3 0]);
% or equivalently wpsplt(wpt,7).
```

% Plot wavelet packet tree wpt.
plot(wpt)

wpthcoef

Wavelet packet coefficients thresholding

Syntax

NT = wpthcoef(T, KEEPAPP, SORH, THR)

Description

wpthcoef is a one- or two-dimensional de-noising and compression utility.

NT = wpthcoef(*T*, KEEPAPP, SORH, THR) returns a new wavelet packet tree NT obtained from the wavelet packet tree *T* by coefficients thresholding.

If KEEPAPP = 1, approximation coefficients are not thresholded; otherwise, they can be thresholded.

If SORH = 's', soft thresholding is applied; if SORH = 'h', hard thresholding is applied (see wthresh for more information).

THR is the threshold value.

wpdec | wpdec2 | wpdencmp | wthresh

wptree

WPTREE constructor

Syntax

```
T = wptree(ORDER,DEPTH,X,WNAME,ENT_TYPE,PARAMETER)
T = wptree(ORDER,DEPTH,X,WNAME)
T = wptree(ORDER,DEPTH,X,WNAME,'shannon')
T = wptree(ORDER,DEPTH,X,WNAME,ENT TYPE,ENT PAR,USERDATA)
```

Description

T = wptree(ORDER, DEPTH, X, WNAME, ENT_TYPE, PARAMETER) returns a complete wavelet packet tree T.

ORDER is an integer representing the order of the tree (the number of "children" of each non terminal node). ORDER must be equal to 2 or 4.

If ORDER = 2, T is a WPTREE object corresponding to a wavelet packet decomposition of the vector (signal) X, at level DEPTH with a particular wavelet WNAME.

If ORDER = 4, T is a WPTREE object corresponding to a wavelet packet decomposition of the matrix (image) X, at level DEPTH with a particular wavelet WNAME.

ENT_TYPE is a string containing the entropy type and ENT_PAR is an optional parameter used for entropy computation (see wentropy, wpdec, or wpdec2 for more information).

```
T = wptree(ORDER,DEPTH,X,WNAME) is equivalent to T = wptree(ORDER,DEPTH,X,WNAME,'shannon')
```

With T = wptree(ORDER, DEPTH, X, WNAME, ENT_TYPE, ENT_PAR, USERDATA) you may set a userdata field.

The function wptree returns a WPTREE object.

For more information on object fields, see the get function or type

help wptree/get

Class WPTREE (Parent class: DTREE)

Fields

'dtree'	DTREE parent object
'wavInfo'	Structure (wavelet information)
'entInfo'	Structure (entropy information)

The wavelet information structure, 'wavInfo', contains

'wavName'	Wavelet name
'Lo_D'	Low Decomposition filter
'Hi_D'	High Decomposition filter
'Lo_R'	Low Reconstruction filter
'Hi_R'	High Reconstruction filter

The entropy information structure, 'entInfo', contains

'entName'	Entropy name
'entPar'	Entropy parameter

Fields from the DTREE parent object:

'allNI'	All nodes information
---------	-----------------------

'allNI' is an array of size $nbnode\ by\ 5,$ which contains

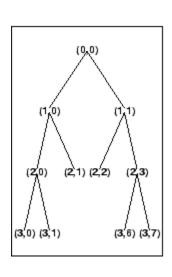

ind	Index
size	Size of data
ent	Entropy
ento	Optimal entropy

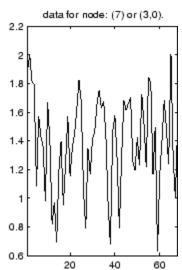

Each line is built based on the following scheme:

Examples

```
% Create a wavelet packet tree.
x = rand(1,512);
t = wptree(2,3,x,'db3');
t = wpjoin(t,[4;5]);
% Plot tree t4.
plot(t);
% Click the node (3,0), (see the plot function).
```

wpviewcf

Plot wavelet packets colored coefficients

Syntax

```
wpviewcf(T,CMODE)
wpviewcf(T,CMODE,NBCOL)
```

Description

wpviewcf(T, CMODE) plots the colored coefficients for the terminal nodes of the tree T.

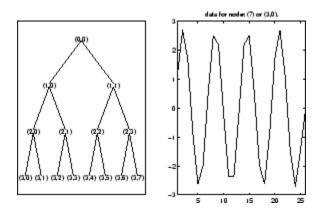

T is a wavelet packet tree and CMODE is an integer, which represents the color mode. The color modes are listed in the table below.

Color Mode	Description
1	Frequency order – Global coloration – Absolute values
2	Frequency order – By level – Absolute values
3	Frequency order – Global coloration – Values
4	Frequency order – By level coloration – Values
5	Natural order – Global coloration – Absolute values
6	Natural order – By level – Absolute values
7	Natural order – Global coloration – Values
8	Natural order – By level coloration – Values

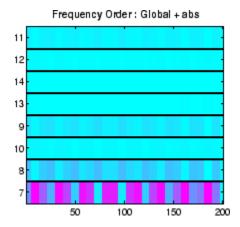

wpviewcf(T,CMODE,NBCOL) uses NBCOL colors.

```
% Create a wavelet packet tree.
x = sin(8*pi*[0:0.005:1]);
t = wpdec(x,3,'db1');
```

```
% Plot tree t. % Click the node (3,0), (see the plot function) plot(t);
```

% Plot the colored wavelet packet coefficients. wpviewcf(t,1);

wpdec

wrcoef

Reconstruct single branch from 1-D wavelet coefficients

Syntax

```
X = wrcoef('type',C,L,'wname',N)
X = wrcoef('type',C,L,Lo_R,Hi_R,N)
X = wrcoef('type',C,L,'wname')
X = wrcoef('type',C,L,Lo_R,Hi_R)
```

Description

wrcoef reconstructs the coefficients of a one-dimensional signal, given a wavelet decomposition structure (C and L) and either a specified wavelet ('wname', see wfilters for more information) or specified reconstruction filters (Lo R and Hi R).

X = wrcoef('type',C,L,'wname',N) computes the vector of reconstructed coefficients, based on the wavelet decomposition structure [C,L] (see wavedec for more information), at level N. 'wname' is a string containing the wavelet name.

Argument 'type' determines whether approximation ('type' = 'a') or detail ('type' = 'd') coefficients are reconstructed. When 'type' = 'a', N is allowed to be 0; otherwise, a strictly positive number N is required. Level N must be an integer such that $N \le length(L) - 2$.

X = wrcoef('type',C,L,Lo_R,Hi_R,N) computes coefficients as above, given the reconstruction filters you specify.

```
X = wrcoef('type',C,L,'wname') and X = wrcoef('type',C,L,Lo_R,Hi_R) reconstruct coefficients of maximum level N = length(L)-2.
```

Examples

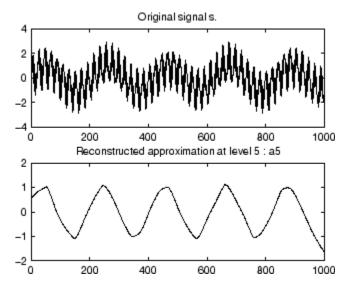

% The current extension mode is zero-padding (see dwtmode).

```
% Load a one-dimensional signal.
load sumsin; s = sumsin;

% Perform decomposition at level 5 of s using sym4.
[c,l] = wavedec(s,5,'sym4');

% Reconstruct approximation at level 5,
% from the wavelet decomposition structure [c,l].
a5 = wrcoef('a',c,l,'sym4',5);

% Using some plotting commands,
% the following figure is generated.
```

See Also appcoef | detcoef | wavedec

wrcoef2

Reconstruct single branch from 2-D wavelet coefficients

Syntax

```
X = wrcoef2('type',C,S,'wname',N)
X = wrcoef2('type',C,S,Lo_R,Hi_R,N)
X = wrcoef2('type',C,S,'wname')
X = wrcoef2('type',C,S,Lo_R,Hi_R)
```

Description

wrcoef2 is a two-dimensional wavelet analysis function. wrcoef2 reconstructs the coefficients of an image.

X = wrcoef2('type',C,S,'wname',N) computes the matrix of reconstructed coefficients of level N, based on the wavelet decomposition structure [C,S] (see wavedec2 for more information).

'wname' is a string containing the name of the wavelet (see wfilters for more information). If 'type' = 'a', approximation coefficients are reconstructed; otherwise if 'type' = 'h' ('v' or 'd', respectively), horizontal (vertical or diagonal, respectively) detail coefficients are reconstructed.

Level N must be an integer such that $0 \le N \le \text{size}(S,1) - 2$ if 'type' = 'a' and such that $1 \le N \le \text{size}(S,1) - 2$ if 'type' = 'h', 'v', or 'd'.

Instead of giving the wavelet name, you can give the filters.

For $X = \text{wrcoef2}('type',C,S,Lo_R,Hi_R,N)$, Lo_R is the reconstruction low-pass filter and Hi_R is the reconstruction high-pass filter.

X = wrcoef2('type',C,S,'wname') or X = wrcoef2('type',C,S,Lo_R,Hi_R)
reconstruct coefficients of maximum level N = size(S,1)-2.

Examples

% The current extension mode is zero-padding (see dwtmode).

```
% Load an image.
load woman;
% X contains the loaded image.
% Perform decomposition at level 2
% of X using sym5.
[c,s] = wavedec2(X,2,'sym5');
% Reconstruct approximations at
% levels 1 and 2, from the wavelet
% decomposition structure [c,s].
a1 = wrcoef2('a',c,s,'sym5',1);
a2 = wrcoef2('a',c,s,'sym5',2);
% Reconstruct details at level 2,
% from the wavelet decomposition
% structure [c,s].
% 'h' is for horizontal,
% 'v' is for vertical,
% 'd' is for diagonal.
hd2 = wrcoef2('h',c,s,'sym5',2);
vd2 = wrcoef2('v',c,s,'sym5',2);
dd2 = wrcoef2('d',c,s,'sym5',2);
% All these images are of same size sX.
sX = size(X)
sX =
 256 256
sa1 = size(a1)
sa1 =
 256 256
shd2 = size(hd2)
shd2 =
 256 256
```

More About

Tips

If C and S are obtained from an indexed image analysis (respectively a truecolor image analysis) then X is an m-by-n matrix (respectively an m-by-n-by-3 array).

For more information on image formats, see the reference pages of image and imfinfo functions.

wrev

Flip vector

Syntax

```
Y = wrev(X)
```

Description

wrev is a general utility.

Y = wrev(X) reverses the vector X.

Examples

```
v = [1 2 3];
wrev(v)
wrev(v')
```

fliplr | flipud

write

Write values in WPTREE fields

Syntax

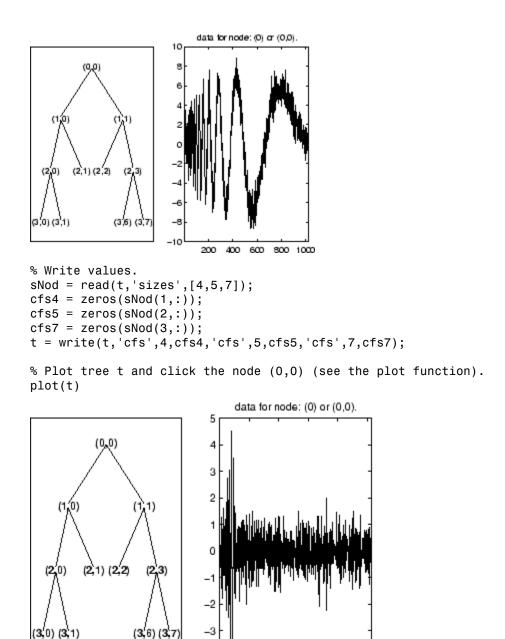

```
T = write(T,'cfs',NODE,COEFS)
T = write(T,'cfs',N1,CFS1,'cfs',N2,CFS2, ...)
```

Description

```
T = write(T,'cfs',NODE,COEFS) writes coefficients for the terminal node NODE.
T = write(T,'cfs',N1,CFS1,'cfs',N2,CFS2, ...) writes coefficients CFS1,
CFS2, ... for the terminal nodes N1, N2, ....
```

Caution The coefficients values must have the suitable size. You can use S = read(T, 'sizes', NODE) or S = read(T, 'sizes', [N1; N2; ...]) in order to get those sizes.

```
% Create a wavelet packet tree.
load noisdopp; x = noisdopp;
t = wpdec(x,3,'db3');
t = wpjoin(t,[4;5]);
% Plot tree t and click the node (0,0) (see the plot function).
plot(t);
```

wscalogram

Scalogram for continuous wavelet transform

Syntax

```
SC = wscalogram(TYPEPLOT,COEFS)
SC = wscalogram(TYPEPLOT,COEFS,'PropName1',PropVal1,...)
```

Description

SC = wscalogram(TYPEPLOT, COEFS) computes the scalogram SC which represents the percentage of energy for each coefficient. COEFS is the matrix of the continuous wavelet coefficients (see cwt).

The scalogram is obtained by computing:

```
S = abs(coefs.*coefs); SC = 100*S./sum(S(:))
```

When TYPEPLOT is equal to 'image', a scaled image of scalogram is displayed. When TYPEPLOT is equal to 'contour', a contour representation of scalogram is displayed. Otherwise, the scalogram is returned without plot representation.

SC = wscalogram(TYPEPLOT, COEFS, 'PropName1', PropVal1,...) allows you to modify some properties. The valid choices for PropName are:

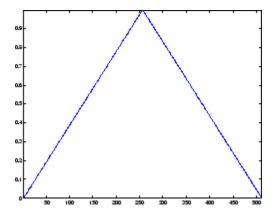

'scales'	Scales used for the CWT.
'ydata'	Signal used for the CWT.
'xdata'	x values corresponding to the signal values.
'power'	Positive real value. Default value is zero.

If power > 0, coefficients are first normalized

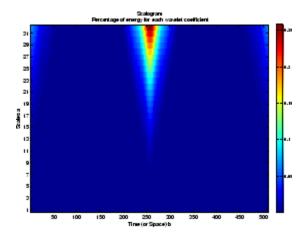

```
coefs(k,:) = coefs(k,:)/(scales(k)^power)
```

and then the scalogram is computed as explained above.

```
% Compute signal s
t = linspace(-1,1,512);
s = 1-abs(t);
% Plot signal s
figure;
plot(s), axis tight
```

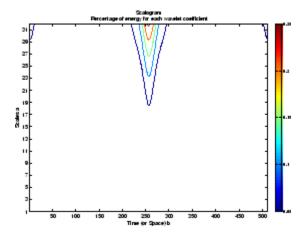

```
% Compute coefficients COEFS using cwt
COEFS = cwt(s,1:32,'cgau4');
% Compute and plot the scalogram (image option)
figure;
SC = wscalogram('image',COEFS);
```

 $\mbox{\%}$ Compute and plot the scalogram (contour option) figure;

SC = wscalogram('contour', COEFS);

wtbo

WTBO constructor

Syntax

OBJ = wtbo OBJ = wtbo(USERDATA)

Description

OBJ = wtbo returns a WTBO object. Any object in the Wavelet Toolbox software is parented by a WTBO object.

With OBJ = wtbo (USERDATA) you can set a userdata field.

Class WTBO (Parent class: none)

Fields

wtboInfo	Object information (not used in the current version of the toolbox)
ud	Userdata field

wtbxmngr

Wavelet Toolbox manager

Syntax

```
wtbxmngr(OPTION)
V = wtbxmngr('version')
```

Description

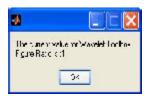

wtbxmngr or wtbxmngr('version') displays the current version of Wavelet Toolbox software.

wtbxmngr(OPTION) sets a toolbox option. Available options are

Option	Description
'LargeFonts'	Sets the size of future-created figures to use large fonts.
'DefaultSize'	Restores the default figure size for future- created figures.
'FigRatio'	Returns the current figure ratio value.
'FigRatio',ratio	Changes the size of future-created figures by multiplying the default size by the specified ratio, where ratio must be between 0.75 and 1.25.

V = wtbxmngr('version') saves the current version of the toolbox to variable V.

```
wtbxmngr('FigRatio') % Display the current figure ratio
wtbxmngr('FigRatio',1.25) % Set the figure ratio to 1.25
wtbxmngr('FigRatio') % Display the current figure ratio
wtbxmngr('DefaultSize') % Return to the default figure ratio
```

wthcoef

1-D wavelet coefficient thresholding

Syntax

```
NC = wthcoef('d',C,L,N,P)
NC = wthcoef('d',C,L,N)
NC = wthcoef('a',C,L)
NC = wthcoef('t',C,L,N,T,SORH)
```

Description

wthcoef thresholds wavelet coefficients for the denoising or compression of a 1-D signal.

NC = wthcoef('d',C,L,N,P) returns coefficients obtained from the wavelet decomposition structure [C,L] (see wavedec for more information), by rate compression defined in vectors N and P. N contains the detail levels to be compressed and P the corresponding percentages of lower coefficients to be set to zero. N and P must be of same length. Vector N must be such that $1 \le N(i) \le length(L) - 2$.

NC = wthcoef('d',C,L,N) returns coefficients obtained from [C,L] by setting all the coefficients of detail levels defined in N to zero.

NC = wthcoef('a',C,L) returns coefficients obtained by setting approximation coefficients to zero.

NC = wthcoef('t',C,L,N,T,SORH) returns coefficients obtained from the wavelet decomposition structure [C,L] by soft (if SORH ='s') or hard (if SORH ='h') thresholding (see wthresh for more information) defined in vectors N and T. N contains the detail levels to be thresholded and T the corresponding thresholds. N and T must be of the same length.

[NC,L] is the modified wavelet decomposition structure.

wavedec | wthresh

wthcoef2

Wavelet coefficient thresholding 2-D

Syntax

```
NC = wthcoef2('type',C,S,N,T,SORH)
NC = wthcoef2('type',C,S,N)
NC = wthcoef2('a',C,S)
NC = wthcoef2('t',C,S,N,T,SORH)
```

Description

wthcoef2 is a two-dimensional de-noising and compression oriented function.

For 'type' = 'h' ('v' or 'd'), NC = wthcoef2('type',C,S,N,T,SORH) returns the horizontal (vertical or diagonal, respectively) coefficients obtained from the wavelet decomposition structure [C,S] (see wavedec2 for more information), by soft (if SORH = 's') or hard (if SORH = 'h') thresholding defined in vectors N and T. N contains the detail levels to be thresholded and T the corresponding thresholds. N and T must be of the same length. The vector N must be such that $1 \le N(i) \le size(S,1)-2$.

For 'type' = 'h' ('v' or 'd'), NC = wthcoef2('type',C,S,N) returns the horizontal (vertical or diagonal, respectively) coefficients obtained from [C,S] by setting all the coefficients of detail levels defined in N to zero.

NC = wthcoef2('a',C,S) returns the coefficients obtained by setting approximation coefficients to zero.

NC = wthcoef2('t',C,S,N,T,SORH) returns the detail coefficients obtained from the wavelet decomposition structure [C,S] by soft (if SORH = 's') or hard (if SORH = 'h') thresholding (see wthresh for more information) defined in vectors N and T. N contains the detail levels to be thresholded and T the corresponding thresholds which are applied in the three detail orientations. N and T must be of the same length.

[NC,S] is the modified wavelet decomposition structure.

wavedec2 | wthresh

wthresh

Soft or hard thresholding

Syntax

```
Y = wthresh(X,SORH,T)
Y = wthresh(X,'s',T)
Y = wthresh(X,'h',T)
```

Description

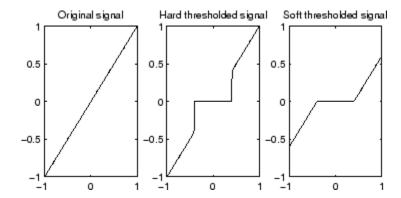

```
Y = wthresh(X, SORH, T) returns the soft (if SORH = 's') or hard (if SORH = 'h') thresholding of the input vector or matrix X. T is the threshold value.
```

```
Y = wthresh(X,'s',T) returns Y = sign(X) \cdot (|X| - T)_+, soft thresholding is wavelet shrinkage ((x)<sub>+</sub> = 0 if x < 0; (x)<sub>+</sub> = x, if x \geq 0).
```

```
Y = \text{wthresh}(X, h', T) \text{ returns } Y = X.1(|X| > T), \text{ hard thresholding is cruder.}
```

Examples

```
% Generate signal and set threshold.
y = linspace(-1,1,100);
thr = 0.4;
% Perform hard thresholding.
ythard = wthresh(y,'h',thr);
% Perform soft thresholding.
ytsoft = wthresh(y,'s',thr);
% Using some plotting commands,
% the following figure is generated.
```

wthrmngr

Threshold settings manager

Syntax

THR = wthrmngr(OPTION, METHOD, VARARGIN)

Description

THR = wthrmngr(OPTION, METHOD, VARARGIN) returns a global threshold or level dependent thresholds depending on OPTION. The inputs, VARARGIN, depend on the OPTION and METHOD values.

This file returns the thresholds used throughout the Wavelet Toolbox software for denoising and compression tools (command line files or GUI tools).

Valid options for the METHOD parameter are listed in the table below.

METHOD	Description
'scarcehi'	See wdcbm or wdcbm2 when used with 'high' predefined value of parameter M.
'scarceme'	See wdcbm or wdcbm2 when used with 'medium' predefined value of parameter M.
'scarcelo'	See wdcbm or wdcbm2 when used with 'low' predefined value of parameter M.
'sqtwolog'	See 'sqtwolog' option in thselect, and see also wden.
'sqtwologuwn'	See 'sqtwolog' option in thselect, and see also wden when used with 'sln' option.
'sqtwologswn'	See 'sqtwolog' option in thselect, and see also wden when used with 'mln' option.
'rigsure'	See 'rigsure' option in thselect, and see also wden.
'heursure'	See 'heursure' option in thselect, and see also wden.
'minimaxi'	See 'minimaxi' option in thselect, and see also wden.

METHOD	Description
'penalhi'	See wbmpen or wpbmpen when used with 'high' value of parameter ALPHA.
'penalme'	See wbmpen or wpbmpen when used with 'medium' value of parameter ALPHA.
'penallo'	See wbmpen or wpbmpen when used with 'low' value of parameter ALPHA.
'rem_n0'	This option returns a threshold close to 0. A typical THR value is median(abs(coefficients)).
'bal_sn'	This option returns a threshold such that the percentages of retained energy and number of zeros are the same.
'sqrtbal_sn'	This option returns a threshold equal to the square root of the value such that the percentages of retained energy and number of zeros are the same.

Discrete Wavelet 1-D Options

For 1–D wavelet transforms, the expansion coefficients are in the vector **C** and the lengths of the expansion coefficient vectors are stored in L.

Compression using a global threshold.

X is the signal to be compressed and [C,L] is the wavelet decomposition structure of the signal to be compressed.

```
THR = wthrmngr('dw1dcompGBL','rem_n0',X)
THR = wthrmngr('dw1dcompGBL','bal sn',X)
```

Compression using level dependent thresholds.

X is the signal to be compressed and [C,L] is the wavelet decomposition structure of the signal to be compressed.

ALFA is a sparsity parameter (see wdcbm for more information).

```
THR = wthrmngr('dw1dcompLVL','scarcehi',C,L,ALFA)
         ALFA must be such that 2.5 < ALFA < 10
THR = wthrmngr('dw1dcompLVL','scarceme',C,L,ALFA)
         ALFA must be such that 1.5 < ALFA < 2.5</pre>
```

De-noising using level dependent thresholds.

[C,L] is the wavelet decomposition structure of the signal to be de-noised, SCAL defines the multiplicative threshold rescaling (see wden for more information) and ALFA is a sparsity parameter (see wbmpen for more information).

Discrete Stationary Wavelet 1-D Options

De-noising using level dependent thresholds.

SWTDEC is the stationary wavelet decomposition structure of the signal to be de-noised, SCAL defines the multiplicative threshold rescaling (see wden for more information) and ALFA is a sparsity parameter (see wbmpen for more information).

```
THR = wthrmngr('sw1ddenoLVL',METHOD,SWTDEC,SCAL)
THR = wthrmngr('sw1ddenoLVL',METHOD,SWTDEC,ALFA)
```

The options for METHOD are the same as in the 'dw1ddenoLVL'case.

Discrete Wavelet 2-D Options

For 2–D wavelet transforms, the expansion coefficients are in the vector C and the size of the coefficient matrices at each level is stored in S.

Compression using a global threshold.

X is the image to be compressed and [C,S] is the wavelet decomposition structure of the image to be compressed.

```
THR = wthrmngr('dw2dcompGBL','rem_n0',X)
THR = wthrmngr('dw2dcompGBL','ba1_sn',C,S)
THR = wthrmngr('dw2dcompGBL','sqrtba1_sn',C,S)
```

Compression using level dependent thresholds.

X is the image to be compressed and [C,S] is the wavelet decomposition structure of the image to be compressed. ALFA is a sparsity parameter (see wdcbm2 for more information).

De-noising using level dependent thresholds.

[C,S] is the wavelet decomposition structure of the image to be de-noised, SCAL defines the multiplicative threshold rescaling (see wden for more information) and ALFA is a sparsity parameter (see wbmpen for more information).

Discrete Stationary Wavelet 2-D Options

De-noising using level dependent thresholds.

SWTDEC is the stationary wavelet decomposition structure of the image to be de-noised, SCAL defines the multiplicative threshold rescaling (see wden for more information) and ALFA is a sparsity parameter (see wbmpen for more information).

```
THR = wthrmngr('sw2ddenoLVL',METHOD,SWTDEC,SCAL)
THR = wthrmngr('sw2ddenoLVL',METHOD,SWTDEC,ALFA)
```

The options for METHOD are the same as in the 'dw2ddenoLVL' case.

Discrete Wavelet Packet 1-D Options

Compression using a global threshold.

X is the signal to be compressed and WPT is the wavelet packet decomposition structure of the signal to be compressed.

```
THR = wthrmngr('wp1dcompGBL','ba1_sn',WPT)
THR = wthrmngr('wp1dcompGBL','rem n0',X)
```

De-noising using a global threshold.

WPT is the wavelet packet decomposition structure of the signal to be de-noised.

```
THR = wthrmngr('wp1ddenoGBL', 'sqtwologuwn',WPT)
THR = wthrmngr('wp1ddenoGBL', 'sqtwologswn',WPT)
THR = wthrmngr('wp1ddenoGBL', 'bal_sn',WPT)
THR = wthrmngr('wp1ddenoGBL', 'penalhi',WPT)
         see wbmpen with ALFA = 6.25
THR = wthrmngr('wp1ddenoGBL', 'penalme',WPT)
         see wbmpen with ALFA = 2
THR = wthrmngr('wp1ddenoGBL', 'penallo',WPT)
         see wbmpen with ALFA = 1.5
```

Discrete Wavelet Packet 2-D Options

Compression using a global threshold.

X is the image to be compressed and WPT is the wavelet packet decomposition structure of the image to be compressed.

```
THR = wthrmngr('wp2dcompGBL','bal_sn',WPT)
THR = wthrmngr('wp2dcompGBL','rem_n0',X)
THR = wthrmngr('wp2dcompGBL','sqrtbal_sn',WPT)
```

De-noising using a global threshold.

WPT is the wavelet packet decomposition structure of the image to be de-noised.

```
THR = wthrmngr('wp2ddenoGBL','sqtwologuwn',WPT)
THR = wthrmngr('wp2ddenoGBL','sqtwologswn',WPT)
THR = wthrmngr('wp2ddenoGBL','sqrtbal_sn',WPT)
```

```
THR = wthrmngr('wp2ddenoGBL', 'penalhi', WPT)
    see wbmpen with ALFA = 6.25
THR = wthrmngr('wp2ddenoGBL', 'penalme', WPT)
    see wbmpen with ALFA = 2
THR = wthrmngr('wp2ddenoGBL', 'penallo', WPT)
    see wbmpen with ALFA = 1.5
```

Examples

Level-Independent Threshold — Stationary Wavelet Transform

This example uses a level-independent threshold based on the finest-scale wavelet coefficients to implement hard thresholding with the stationary wavelet transform.

Load the noisy blocks signal. Obtain the stationary wavelet transform down to level 5 using the Haar wavelet.

```
load noisbloc;
L = 5;
swc = swt(noisbloc,L,'db1');
```

Make a copy of the wavelet transform coefficients. Determine the Donoho-Johnstone universal threshold based on the first-level detail coefficients. Using the 'sln' option, wthrmngr returns a 1-by-L vector with every element equal to the same value. Take the mean of the vector to obtain a scalar threshold.

```
swcnew = swc;
ThreshSL = mean(wthrmngr('sw1ddenoLVL','sqtwolog',swc,'sln'));
```

Use the universal threshold to implement hard thresholding. The same threshold is applied to the wavelet coefficients at every level.

```
for jj = 1:L
swcnew(jj,:) = wthresh(swc(jj,:),'h',ThreshSL);
end
```

Invert the stationary wavelet transform on the thresholded coefficients, swcnew. Plot the original signal and the denoised signal for comparison.

```
noisbloc_denoised = iswt(swcnew, 'db1');
plot(noisbloc); hold on;
```

```
plot(noisbloc_denoised, 'r', 'linewidth',2);
```

Level-Dependent Threshold — Stationary Wavelet Transform

This example uses a level-dependent threshold derived from the wavelet coefficients at each scale to implement hard thresholding with the stationary wavelet transform.

Load the noisy blocks signal. Obtain the stationary wavelet transform down to level 5 using the Haar wavelet.

```
load noisbloc;
L = 5;
swc = swt(noisbloc,L,'db1');
```

Make a copy of the wavelet transform coefficients. Determine the Donoho-Johnstone universal threshold based on the detail coefficients for each scale. Using the 'mln' option, wthrmngr returns a 1-by-L vector with each element of the vector equal to the universal threshold for the corresponding scale.

```
swcnew = swc;
ThreshML = wthrmngr('sw1ddenoLVL','sqtwolog',swc,'mln');
```

Use the universal thresholds to implement hard thresholding. The thresholds are applied in a scale-dependent manner.

```
for jj = 1:L
swcnew(jj,:) = wthresh(swc(jj,:),'h',ThreshML(jj));
end
```

Invert the stationary wavelet transform on the thresholded coefficients, swcnew. Plot the original signal and the denoised signal for comparison.

```
noisbloc_denoised = iswt(swcnew, 'db1');
plot(noisbloc); hold on;
plot(noisbloc_denoised, 'r', 'linewidth', 2);
```

Image Compression — Birgé-Massart Thresholds

This example compresses an image using the Birgé-Massart strategy.

Load the image and add white Gaussian noise.

```
load sinsin
```

```
x = X+18*randn(size(X));
```

Obtain the 2-D discrete wavelet transform down to level 2 using the Daubechies' least-asymmetric wavelet with 8 vanishing moments. Obtain the compression thresholds using the Birgé-Massart strategy with alpha equal to 2.

```
[C,L] = wavedec2(x,2,'sym8');
alpha = 2;
THR = wthrmngr('dw2dcompLVL','scarcehi',C,L,alpha);
Compress the image and display the result.

Xd = wdencmp('lvd',X,'sym8',2,THR,'s');
image(X); title('Original image');
figure;
image(x); title('Noisy image');
figure;
image(Xd); title('Denoised image');
```

wtreemgr

NTREE manager

Syntax

Description

wtreemgr is a tree management utility.

This function returns information on the tree T depending on the value of the OPT parameter.

Allowed values for OPT are listed in the table below.

'allnodes'	Tree nodes
'isnode'	True for existing node
'istnode'	True for terminal nodes
'nodeasc'	Node ascendants
'nodedesc'	Node descendants
'nodepar'	Node parent
'ntnode'	Number of terminal nodes
'tnodes'	Terminal nodes
'leaves'	Terminal nodes
'noleaves'	Not terminal nodes
'order'	Tree order
'depth'	Tree depth

See Also

allnodes | | istnode | leaves | nodeasc | nodedesc | nodepar | noleaves | ntnode | tnodes | treedpth | treeord

wvarchg

Find variance change points

Syntax

```
[PTS OPT,KOPT,T EST] = wvarchg(Y,K,D)
```

Description

[PTS_OPT, KOPT, T_EST] = wvarchg(Y, K, D) computes estimated variance change points for the signal Y for j change points, with j = 0, 1, 2, ..., K.

Integer D is the minimum delay between two change points.

Integer KOPT is the proposed number of change points ($0 \le KOPT \le K$). The vector PTS_OPT contains the corresponding change points.

For $1 \le k \le K$, $T_EST(k+1,1:k)$ contains the k instants of the variance change points and then, if KOPT > 0, PTS_OPT = $T_EST(KOPT+1,1:KOPT)$ else PTS_OPT = [].

K and D must be integers such that $1 \le K \le length(Y)$ and $1 \le D \le length(Y)$.

The signal Y should be zero mean.

wvarchg(Y,K) is equivalent to wvarchg(Y,K,10).

wvarchg(Y) is equivalent to wvarchg(Y,6,10).

Examples

Detect Variance Change Points

Add two variance change points to the blocks signal. Detect the variance change points using wvarchg.

Load the blocks signal. Add white noise with two variance change points located at index 180 and 600.

```
x = wnoise(1,10);
rng default;
bb = 1.5*randn(1,length(x));
cp1 = 180; cp2 = 600;
x = x + [bb(1:cp1),bb(cp1+1:cp2)/4,bb(cp2+1:end)];
```

Obtain the level-1 wavelet coefficients. Replace the top 2% of values with the mean value of the wavelet coefficients to remove all signal.

```
wname = 'db3'; lev = 1;
[c,1] = wavedec(x,lev,wname);
det = wrcoef('d',c,l,wname,1);
y = sort(abs(det));
v2p100 = y(fix(length(y)*0.98));
ind = find(abs(det)>v2p100);
det(ind) = mean(det);
```

Estimate the variance change points using the wavelet coefficients.

```
[pts_Opt,kopt,t_est] = wvarchg(det,5);
sprintf('The estimated change points are %d and %d\n',pts_Opt)
```
