nag_1d_quad_wt_trig (d01anc)

1 Purpose

nag_1d_quad_wt_trig (d01anc) calculates an approximation to the sine or the cosine transform of a function g over $[a, b]$:

$$I = \int_a^b g(x) \sin(\omega x) dx \quad \text{or} \quad I = \int_a^b g(x) \cos(\omega x) dx$$

(for a user-specified value of ω).

2 Specification

```
#include <nag.h>
#include <nagd01.h>

void nag_1d_quad_wt_trig (double (*g)(double x),
                           double a, double b, double omega, Nag_TrigTransform wt_func,
                           double epsabs, double epsrel, Integer max_num_subint,
                           double *result, double *abserr, Nag_QuadProgress *qp, NagError *fail)
```

3 Description

This function is based upon the QUADPACK routine QFOUR (Piessens *et al.* (1983)). It is an adaptive routine, designed to integrate a function of the form $g(x)w(x)$, where $w(x)$ is either $\sin(\omega x)$ or $\cos(\omega x)$. If a sub-interval has length

$$L = |b - a|2^{-l}$$

then the integration over this sub-interval is performed by means of a modified Clenshaw-Curtis procedure (Piessens and Branders (1975)) if $L\omega > 4$ and $l \leq 20$. In this case a Chebyshev-series approximation of degree 24 is used to approximate $g(x)$, while an error estimate is computed from this approximation together with that obtained using Chebyshev-series of degree 12. If the above conditions do not hold then Gauss 7-point and Kronrod 15-point rules are used. The algorithm, described in Piessens *et al.* (1983), incorporates a global acceptance criterion (as defined in Malcolm and Simpson (1976)) together with the ϵ -algorithm (Wynn (1956)) to perform extrapolation. The local error estimation is described in Piessens *et al.* (1983).

4 Parameters

1: **g** – function supplied by user *Function*

The function **g**, supplied by the user, must return the value of the function g at a given point.

The specification of **g** is:

```
double g(double x)

1:   x – double
      On entry: the point at which the function  $g$  must be evaluated.
```

2: **a** – double *Input*

On entry: the lower limit of integration, a .

3:	b – double	<i>Input</i>
<i>On entry:</i> the upper limit of integration, b . It is not necessary that $a < b$.		
4:	omega – double	<i>Input</i>
<i>On entry:</i> the parameter ω in the weight function of the transform.		
5:	wt_func – Nag_TrigTransform	<i>Input</i>
<i>On entry:</i> indicates which integral is to be computed:		
if wt_func = Nag_Cosine, $w(x) = \cos(\omega x)$;		
if wt_func = Nag_Sine, $w(x) = \sin(\omega x)$.		
<i>Constraint:</i> wt_func = Nag_Cosine or Nag_Sine.		
6:	epsabs – double	<i>Input</i>
<i>On entry:</i> the absolute accuracy required. If epsabs is negative, the absolute value is used. See Section 6.1.		
7:	epsrel – double	<i>Input</i>
<i>On entry:</i> the relative accuracy required. If epsrel is negative, the absolute value is used. See Section 6.1.		
8:	max_num_subint – Integer	<i>Input</i>
<i>On entry:</i> the upper bound on the number of sub-intervals into which the interval of integration may be divided by the function. The more difficult the integrand, the larger max_num_subint should be.		
<i>Suggested values:</i> a value in the range 200 to 500 is adequate for most problems.		
<i>Constraint:</i> max_num_subint ≥ 1 .		
9:	result – double *	<i>Output</i>
<i>On exit:</i> the approximation to the integral I .		
10:	abserr – double *	<i>Output</i>
<i>On exit:</i> an estimate of the modulus of the absolute error, which should be an upper bound for $ I - \text{result} $.		
11:	qp – Nag_QuadProgress *	
Pointer to structure of type Nag_QuadProgress with the following members:		
num_subint – Integer		
<i>On exit:</i> the actual number of sub-intervals used.		
fun_count – Integer		
<i>On exit:</i> the number of function evaluations performed by nag_1d_quad_wt_trig.		
sub_int_beg_pts – double *		
sub_int_end_pts – double *		
sub_int_result – double *		
sub_int_error – double *		
<i>On exit:</i> these pointers are allocated memory internally with max_num_subint elements. If an error exit other than NE_INT_ARG_LT, NE_BAD_PARAM or NE_ALLOC_FAIL occurs, these arrays will contain information which may be useful. For details, see Section 6.		

Before a subsequent call to nag_1d_quad_wt_trig is made, or when the information contained in these arrays is no longer useful, the user should free the storage allocated by these pointers using the NAG macro **NAG_FREE**.

12: **fail** – NagError *

Input/Output

The NAG error parameter (see the Essential Introduction).

Users are recommended to declare and initialise **fail** and set **fail.print = TRUE** for this function.

5 Error Indicators and Warnings

NE_INT_ARG_LT

On entry, **max_num_subint** must not be less than 1: **max_num_subint** = <*value*>.

NE_BAD_PARAM

On entry, parameter **wt_func** had an illegal value.

NE_ALLOC_FAIL

Memory allocation failed.

NE_QUAD_MAX_SUBDIV

The maximum number of subdivisions has been reached: **max_num_subint** = <*value*>.

The maximum number of subdivisions has been reached without the accuracy requirements being achieved. Look at the integrand in order to determine the integration difficulties. If the position of a local difficulty within the interval can be determined (e.g., a singularity of the integrand or its derivative, a peak, a discontinuity, etc.) you will probably gain from splitting up the interval at this point and calling the integrator on the sub-intervals. If necessary, another integrator, which is designed for handling the type of difficulty involved, must be used. Alternatively, consider relaxing the accuracy requirements specified by **epsabs** and **epsrel**, or increasing the value of **max_num_subint**.

NE_QUAD_ROUNDOFF_TOL

Round-off error prevents the requested tolerance from being achieved: **epsabs** = <*value*>, **epsrel** = <*value*>.

The error may be underestimated. Consider relaxing the accuracy requirements specified by **epsabs** and **epsrel**.

NE_QUAD_BAD_SUBDIV

Extremely bad integrand behaviour occurs around the sub-interval (<*value*>, <*value*>).

The same advice applies as in the case of **NE_QUAD_MAX_SUBDIV**.

NE_QUAD_ROUNDOFF_EXTRAPL

Round-off error is detected during extrapolation.

The requested tolerance cannot be achieved, because the extrapolation does not increase the accuracy satisfactorily; the returned result is the best that can be obtained.

The same advice applies as in the case of **NE_QUAD_MAX_SUBDIV**.

NE_QUAD_NO_CONV

The integral is probably divergent or slowly convergent.

Please note that divergence can also occur with any error exit other than **NE_INT_ARG_LT**, **NE_BAD_PARAM** or **NE_ALLOC_FAIL**.

6 Further Comments

The time taken by nag_1d_quad_wt_trig depends on the integrand and the accuracy required.

If the function fails with an error exit other than **NE_INT_ARG_LT**, **NE_BAD_PARAM** or **NE_ALLOC_FAIL**, then the user may wish to examine the contents of the structure **qp**. These contain the end-points of the sub-intervals used by nag_1d_quad_wt_trig along with the integral contributions and error estimates over the sub-intervals.

Specifically, for $i = 1, 2, \dots, n$, let r_i denote the approximation to the value of the integral over the sub-interval $[a_i, b_i]$ in the partition of $[a, b]$ and e_i be the corresponding absolute error estimate.

Then, $\int_{a_i}^{b_i} g(x)w(x) dx \simeq r_i$ and **result** = $\sum_{i=1}^n r_i$ unless the function terminates while testing for divergence of the integral (see Section 3.4.3 of Piessens *et al.* (1983)). In this case, **result** (and **abserr**) are taken to be the values returned from the extrapolation process. The value of n is returned in **num_subint**, and the values a_i , b_i , r_i and e_i are stored in the structure **qp** as

$$\begin{aligned} a_i &= \text{sub_int_beg_pts}[i - 1], \\ b_i &= \text{sub_int_end_pts}[i - 1], \\ r_i &= \text{sub_int_result}[i - 1] \text{ and} \\ e_i &= \text{sub_int_error}[i - 1]. \end{aligned}$$

6.1 Accuracy

The function cannot guarantee, but in practice usually achieves, the following accuracy:

$$|I - \text{result}| \leq tol$$

where

$$tol = \max\{|\text{epsabs}|, |\text{epsrel}| \times |I|\}$$

and **epsabs** and **epsrel** are user-specified absolute and relative error tolerances. Moreover it returns the quantity **abserr** which, in normal circumstances, satisfies

$$|I - \text{result}| \leq \text{abserr} \leq tol.$$
