

NAG C Library Function Document

nag_dgetrf (f07adc)

1 Purpose

nag_dgetrf (f07adc) computes the LU factorization of a real m by n matrix.

2 Specification

```
void nag_dgetrf (Nag_OrderType order, Integer m, Integer n, double a[],
                 Integer pda, Integer ipiv[], NagError *fail)
```

3 Description

nag_dgetrf (f07adc) forms the LU factorization of a real m by n matrix A as $A = PLU$, where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$). Usually A is square ($m = n$), and both L and U are triangular. The function uses partial pivoting, with row interchanges.

5 Parameters

- 1: **order** – Nag_OrderType *Input*
On entry: the **order** parameter specifies the two-dimensional storage scheme being used, i.e., row-major ordering or column-major ordering. C language defined storage is specified by **order** = **Nag_RowMajor**. See Section 2.2.1.4 of the Essential Introduction for a more detailed explanation of the use of this parameter.
Constraint: **order** = **Nag_RowMajor** or **Nag_ColMajor**.
- 2: **m** – Integer *Input*
On entry: m , the number of rows of the matrix A .
Constraint: $m \geq 0$.
- 3: **n** – Integer *Input*
On entry: n , the number of columns of the matrix A .
Constraint: $n \geq 0$.
- 4: **a**[*dim*] – double *Input/Output*
Note: the dimension, *dim*, of the array **a** must be at least $\max(1, \mathbf{pda} \times \mathbf{n})$ when **order** = **Nag_ColMajor** and at least $\max(1, \mathbf{pda} \times \mathbf{m})$ when **order** = **Nag_RowMajor**.
 If **order** = **Nag_ColMajor**, the (i, j) th element of the matrix A is stored in **a**[($j - 1$) $\times$ **pda** + $i - 1$] and if **order** = **Nag_RowMajor**, the (i, j) th element of the matrix A is stored in **a**[($i - 1$) $\times$ **pda** + $j - 1$].
On entry: the m by n matrix A .
On exit: **a** is overwritten by the factors L and U ; the unit diagonal elements of L are not stored.

- 5: **pda** – Integer *Input*
On entry: the stride separating matrix row or column elements (depending on the value of **order**) in the array **a**.
Constraints:
 if **order** = **Nag_ColMajor**, **pda** $\geq \max(1, \mathbf{m})$;
 if **order** = **Nag_RowMajor**, **pda** $\geq \max(1, \mathbf{n})$.
- 6: **ipiv**[*dim*] – Integer *Output*
Note: the dimension, *dim*, of the array **ipiv** must be at least $\max(1, \min(\mathbf{m}, \mathbf{n}))$.
On exit: the pivot indices. Row *i* of the matrix *A* was interchanged with row **ipiv**[*i* – 1] for *i* = 1, 2, ..., $\min(\mathbf{m}, \mathbf{n})$.
- 7: **fail** – NagError * *Output*
 The NAG error parameter (see the Essential Introduction).

6 Error Indicators and Warnings

NE_INT

On entry, **m** = $\langle \text{value} \rangle$.

Constraint: **m** ≥ 0 .

On entry, **n** = $\langle \text{value} \rangle$.

Constraint: **n** ≥ 0 .

On entry, **pda** = $\langle \text{value} \rangle$.

Constraint: **pda** > 0 .

NE_INT_2

On entry, **pda** = $\langle \text{value} \rangle$, **m** = $\langle \text{value} \rangle$.

Constraint: **pda** $\geq \max(1, \mathbf{m})$.

On entry, **pda** = $\langle \text{value} \rangle$, **n** = $\langle \text{value} \rangle$.

Constraint: **pda** $\geq \max(1, \mathbf{n})$.

NE_SINGULAR

$u(\langle \text{value} \rangle, \langle \text{value} \rangle)$ is exactly zero. The factorization has been completed but the factor *U* is exactly singular, and division by zero will occur if it is subsequently used to solve a system of linear equations or to invert *A*.

NE_ALLOC_FAIL

Memory allocation failed.

NE_BAD_PARAM

On entry, parameter $\langle \text{value} \rangle$ had an illegal value.

NE_INTERNAL_ERROR

An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please consult NAG for assistance.

7 Accuracy

The computed factors L and U are the exact factors of a perturbed matrix $A + E$, where

$$|E| \leq c(\min(m, n))\epsilon P|L||U|,$$

$c(n)$ is a modest linear function of n , and ϵ is the *machine precision*.

8 Further Comments

The total number of floating-point operations is approximately $\frac{2}{3}n^3$ if $m = n$ (the usual case), $\frac{1}{3}n^2(3m - n)$ if $m > n$ and $\frac{1}{3}m^2(3n - m)$ if $m < n$.

A call to this function with $m = n$ may be followed by calls to the functions:

nag_dgetrs (f07aec) to solve $AX = B$ or $A^T X = B$;

nag_dgecon (f07agc) to estimate the condition number of A ;

nag_dgetri (f07ajc) to compute the inverse of A .

The complex analogue of this function is nag_zgetrf (f07arc).

9 Example

To compute the LU factorization of the matrix A , where

$$A = \begin{pmatrix} 1.80 & 2.88 & 2.05 & -0.89 \\ 5.25 & -2.95 & -0.95 & -3.80 \\ 1.58 & -2.69 & -2.90 & -1.04 \\ -1.11 & -0.66 & -0.59 & 0.80 \end{pmatrix}.$$
