NAG Toolbox for MATLAB f07pp

1 Purpose

f07pp uses the diagonal pivoting factorization

$$A = UDU^{H}$$
 or $A = LDL^{H}$

to compute the solution to a complex system of linear equations

$$AX = B$$

where A is an n by n Hermitian matrix stored in packed format and X and B are n by r matrices. Error bounds on the solution and a condition estimate are also provided.

2 Syntax

```
[afp, ipiv, x, rcond, ferr, berr, info] = f07pp(fact, uplo, ap, afp, ipiv, b, 'n', n, 'nrhs_p', nrhs_p)
```

3 Description

f07pp performs the following steps:

- 1. If **fact** = 'N', the diagonal pivoting method is used to factor A as $A = UDU^{H}$ if **uplo** = 'U' or $A = LDL^{H}$ if **uplo** = 'L', where U (or L) is a product of permutation and unit upper (lower) triangular matrices and D is Hermitian and block diagonal with 1 by 1 and 2 by 2 diagonal blocks.
- 2. If some $d_{ii} = 0$, so that D is exactly singular, then the function returns with info = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than *machine precision*, $info \ge N + 1$ is returned as a warning, but the function still goes on to solve for X and compute error bounds as described below.
- 3. The system of equations is solved for X using the factored form of A.
- 4. Iterative refinement is applied to improve the computed solution matrix and to calculate error bounds and backward error estimates for it.

5 Parameters

5.1 Compulsory Input Parameters

1: **fact – string**

Specifies whether or not the factorized form of the matrix A has been supplied.

[NP3663/21] f07pp.1

f07pp NAG Toolbox Manual

fact = 'F'

afp and ipiv contain the factorized form of the matrix A. afp and ipiv will not be modified.

fact = 'N'

The matrix A will be copied to **afp** and factorized.

Constraint: fact = 'F' or 'N'.

2: **uplo – string**

If uplo = 'U', the upper triangle of A is stored.

If uplo = 'L', the lower triangle of A is stored.

Constraint: uplo = 'U' or 'L'.

3: ap(*) – complex array

Note: the dimension of the array **ap** must be at least $\max(1, \mathbf{n} \times (\mathbf{n} + 1)/2)$.

The n by n Hermitian matrix A, packed by columns.

More precisely,

if **uplo** = 'U', the upper triangle of A must be stored with element A_{ij} in $\mathbf{ap}(i+j(j-1)/2)$ for i < i:

if **uplo** = 'L', the lower triangle of A must be stored with element A_{ij} in $\mathbf{ap}(i+(2n-j)(j-1)/2)$ for $i \ge j$.

4: afp(*) - complex array

Note: the dimension of the array **afp** must be at least $\max(1, \mathbf{n} \times (\mathbf{n} + 1)/2)$.

If **fact** = 'F', **afp** contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = UDU^{\rm H}$ or $A = LDL^{\rm H}$ as computed by f07pr, stored as a packed triangular matrix in the same storage format as A.

5: ipiv(*) - int32 array

Note: the dimension of the array **ipiv** must be at least $max(1, \mathbf{n})$.

If fact = 'F', **ipiv** contains details of the interchanges and the block structure of D, as determined by f07pr.

Rows and columns k and ipiv(k) were interchanged and D(k,k) is a 1 by 1 diagonal block.

uplo = 'U' and **ipiv**
$$(k)$$
 = **ipiv** $(k-1)$ < 0

Rows and columns k-1 and $-\mathbf{ipiv}(k)$ were interchanged and D(k-1:k,k-1:k) is a 2 by 2 diagonal block.

uplo = 'L' and **ipiv**
$$(k)$$
 = **ipiv** $(k+1)$ < 0

Rows and columns k + 1 and $-\mathbf{ipiv}(k)$ were interchanged and D(k : k + 1, k : k + 1) is a 2 by 2 diagonal block.

6: $b(ldb_{*}) - complex array$

The first dimension of the array **b** must be at least $max(1, \mathbf{n})$

The second dimension of the array must be at least max(1, nrhs p)

The n by r right-hand side matrix B.

f07pp.2 [NP3663/21]

5.2 Optional Input Parameters

1: n - int32 scalar

Default: The dimension of the array ipiv.

n, the number of linear equations, i.e., the order of the matrix A.

Constraint: $\mathbf{n} \geq 0$.

2: nrhs p - int32 scalar

Default: The second dimension of the array b.

r, the number of right-hand sides, i.e., the number of columns of the matrix B.

Constraint: $\mathbf{nrhs}_{\mathbf{p}} \geq 0$.

5.3 Input Parameters Omitted from the MATLAB Interface

ldb, ldx, work, rwork

5.4 Output Parameters

1: afp(*) - complex array

Note: the dimension of the array **afp** must be at least $\max(1, \mathbf{n} \times (\mathbf{n} + 1)/2)$.

If **fact** = 'N', **afp** contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = UDU^{\rm H}$ or $A = LDL^{\rm H}$ as computed by f07pr, stored as a packed triangular matrix in the same storage format as A.

2: ipiv(*) - int32 array

Note: the dimension of the array **ipiv** must be at least $max(1, \mathbf{n})$.

If **fact** = 'N', **ipiv** contains details of the interchanges and the block structure of D, as determined by f07pr.

3: x(ldx,*) – complex array

The first dimension of the array x must be at least $max(1, \mathbf{n})$

The second dimension of the array must be at least max(1, nrhs_p)

If info = 0 or $info \ge N + 1$, the n by r solution matrix X.

4: rcond – double scalar

The estimate of the reciprocal condition number of the matrix A. If $\mathbf{rcond} = 0$, the matrix may be exactly singular. This condition is indicated by a return code of $\mathbf{info} > 0$ leqN. Otherwise, if \mathbf{rcond} is less than the $\mathbf{machine\ precision}$, the matrix is singular to working precision. This condition is indicated by a return code of $\mathbf{info} \geq N+1$.

5: ferr(*) - double array

Note: the dimension of the array ferr must be at least max(1, nrhs p).

If info = 0 or $info \ge N + 1$, an estimate of the forward error bound for each computed solution vector, such that $\|\hat{x}_j - x_j\|_{\infty} / \|x_j\|_{\infty} \le ferr(j)$ where \hat{x}_j is the *j*th column of the computed solution returned in the array \mathbf{x} and x_j is the corresponding column of the exact solution X. The estimate is as reliable as the estimate for **rcond**, and is almost always a slight overestimate of the true error.

[NP3663/21] f07pp.3

f07pp NAG Toolbox Manual

6: berr(*) - double array

Note: the dimension of the array berr must be at least max(1, nrhs p).

If **info** = 0 or **info** $\geq N+1$, an estimate of the component-wise relative backward error of each computed solution vector \hat{x}_j (i.e., the smallest relative change in any element of A or B that makes \hat{x}_j an exact solution).

7: info – int32 scalar

info = 0 unless the function detects an error (see Section 6).

6 Error Indicators and Warnings

Errors or warnings detected by the function:

info = -i

If info = -i, parameter i had an illegal value on entry. The parameters are numbered as follows:

1: fact, 2: uplo, 3: n, 4: nrhs_p, 5: ap, 6: afp, 7: ipiv, 8: b, 9: ldb, 10: x, 11: ldx, 12: rcond, 13: ferr, 14: berr, 15: work, 16: rwork, 17: info.

It is possible that **info** refers to a parameter that is omitted from the MATLAB interface. This usually indicates that an error in one of the other input parameters has caused an incorrect value to be inferred.

info > 0 and **info** < N

If $info \le n$, d(i,i) is exactly zero. The factorization has been completed, but the factor D is exactly singular, so the solution and error bounds could not be computed. **rcond** = 0 is returned.

info = N + 1

D is nonsingular, but **rcond** is less than **machine precision**, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of **rcond** would suggest.

7 Accuracy

For each right-hand side vector b, the computed solution \hat{x} is the exact solution of a perturbed system of equations $(A + E)\hat{x} = b$, where

$$||E||_1 = O(\epsilon)||A||_1$$

where ϵ is the *machine precision*. See Chapter 11 of Higham 2002 for further details.

If \hat{x} is the true solution, then the computed solution x satisfies a forward error bound of the form

$$\frac{\|x - \hat{x}\|_{\infty}}{\|\hat{x}\|_{\infty}} \le w_c \operatorname{cond}(A, \hat{x}, b)$$

where $\operatorname{cond}(A, \hat{x}, b) = \||A^{-1}|(|A||\hat{x}| + |b|)\|_{\infty}/\|\hat{x}\|_{\infty} \le \operatorname{cond}(A) = \||A^{-1}||A|\|_{\infty} \le \kappa_{\infty}(A)$. If \hat{x} is the jth column of X, then w_c is returned in $\operatorname{berr}(j)$ and a bound on $\|x - \hat{x}\|_{\infty}/\|\hat{x}\|_{\infty}$ is returned in $\operatorname{ferr}(j)$. See Section 4.4 of Anderson $et\ al.\ 1999$ for further details.

8 Further Comments

The factorization of A requires approximately $\frac{4}{3}n^3$ floating-point operations.

For each right-hand side, computation of the backward error involves a minimum of $16n^2$ floating-point operations. Each step of iterative refinement involves an additional $24n^2$ operations. At most five steps of

f07pp.4 [NP3663/21]

iterative refinement are performed, but usually only one or two steps are required. Estimating the forward error involves solving a number of systems of equations of the form Ax = b; the number is usually 4 or 5 and never more than 11. Each solution involves approximately $8n^2$ operations.

The real analogue of this function is f07pb.

9 Example

```
fact = 'Not factored';
uplo = 'U';
ap = [complex(-1.84, +0);
      complex(0.11, -0.11);
