NAG Toolbox for MATLAB

f12an

1 Purpose

f12an is a setup function in a suite of functions consisting of f12an, f12ap, f12aq, f12ar and f12as. It is used to find some of the eigenvalues (and optionally the corresponding eigenvectors) of a standard or generalized eigenvalue problem defined by complex nonsymmetric matrices.

The suite of functions is suitable for the solution of large sparse, standard or generalized, nonsymmetric complex eigenproblems where only a few eigenvalues from a selected range of the spectrum are required.

2 Syntax

```
[icomm, comm, ifail] = f12an(n, nev, ncv)
```

3 Description

The suite of functions is designed to calculate some of the eigenvalues, λ, (and optionally the corresponding eigenvectors, x) of a standard complex eigenvalue problem $Ax = \lambda x$, or of a generalized complex eigenvalue problem $Ax = \lambda Bx$ of order n, where n is large and the coefficient matrices A and B are sparse, complex and nonsymmetric. The suite can also be used to find selected eigenvalues/ eigenvectors of smaller scale dense, complex and nonsymmetric problems.

f12an is a setup function which must be called before f12ap, the reverse communication iterative solver, and before f12ar, the options setting function. f12aq is a post-processing function that must be called following a successful final exit from f12ap, while f12as can be used to return additional monitoring information during the computation.

This setup function initializes the communication arrays, sets (to their default values) all options that can be set by you via the option setting function f12ar, and checks that the lengths of the communication arrays as passed by you are of sufficient length. For details of the options available and how to set them see Section 10.2 of the document for f12ar.

5 Parameters

5.1 Compulsory Input Parameters

1: **n – int32 scalar**

The order of the matrix A (and the order of the matrix B for the generalized problem) that defines the eigenvalue problem.

Constraint: $\mathbf{n} > 0$.

2: **nev – int32 scalar**

The number of eigenvalues to be computed.

Constraint: $0 < \mathbf{nev} < \mathbf{n} - 1$.

3: **ncv – int32 scalar**

The number of Arnoldi basis vectors to use during the computation.

At present there is no *a priori* analysis to guide the selection of **ncv** relative to **nev**. However, it is recommended that $\mathbf{ncv} \geq 2 \times \mathbf{nev} + 1$. If many problems of the same type are to be solved, you should experiment with varying **ncv** while keeping **nev** fixed for a given test problem. This will usually decrease the required number of matrix-vector operations but it also increases the work and storage required to maintain the orthogonal basis vectors. The optimal 'cross-over' with respect to CPU time is problem dependent and must be determined empirically.

Constraint: $\mathbf{nev} + 1 < \mathbf{ncv} \leq \mathbf{n}$.

5.2 Optional Input Parameters

None.

5.3 Input Parameters Omitted from the MATLAB Interface

licomm, lcomm

5.4 Output Parameters

1: **icomm**$(*)$ **– int32 array**

Note: the dimension of the array **icomm** must be at least $\max(1, \mathbf{licomm})$.

Contains data to be communicated to the other functions in the suite.

2: **comm**$(*)$ **– complex array**

Note: the dimension of the array **comm** must be at least $\max(1, \mathbf{lcomm})$.

Contains data to be communicated to the other functions in the suite.

3: **ifail – int32 scalar**

0 unless the function detects an error (see Section 6).

6 Error Indicators and Warnings

Errors or warnings detected by the function:

ifail $= 1$

On entry, $\mathbf{n} \leq 0$.

ifail $= 2$

On entry, $\mathbf{nev} \leq 0$.

ifail $= 3$

On entry, $\mathbf{ncv} < \mathbf{nev} + 2$ or $\mathbf{ncv} > \mathbf{n}$.

ifail $= 4$

On entry, $\mathbf{licomm} < 140$ and $\mathbf{licomm} \neq -1$.

ifail $= 5$

On entry, **lcomm** $< 3 \times$ **n** $+ 3 \times$ **ncv** $\times$ **ncv** $+ 5 \times$ **ncv** $+ 60$ and **lcomm** $\neq -1$.

7 Accuracy

Not applicable.

8 Further Comments

None.

9 Example

```
n = int32(100);
nx = int32(10);
nev = int32(4);
ncv = int32(20);

irevcm = int32(0);
resid = complex(zeros(100,1));
v = complex(zeros(100,20));
x = complex(zeros(100,1));
mx = complex(zeros(100,1));

sigma = complex(0);

% Initialisation Step
[icomm, comm, ifail] = f12an(n, nev, ncv);

% Solve
while (irevcm ~= 5)
  [irevcm, resid, v, x, mx, nshift, comm, icomm, ifail] = ...
    f12ap(irevcm, resid, v, x, mx, comm, icomm);
  if (irevcm == 1 || irevcm == -1)
    x = f12_av(nx, x);
  elseif (irevcm == 4)
    [niter, nconv, ritz, rzest] = f12as(icomm, comm);
      fprintf('Iteration %d, No. converged = %d, norm of estimates =
%16.8g\n', niter, nconv, norm(rzest(1:nev),2));
  end
end

% Post-process to compute eigenvalues/vectors
[nconv, d, z, v, comm, icomm, ifail] = f12aq(sigma, resid, v, comm,
icomm);
% sort to avoid different orders showing up as error
```
