

NAG Toolbox for MATLAB

s19ab

1 Purpose

s19ab returns a value for the Kelvin function $\text{bei } x$ via the function name.

2 Syntax

```
[result, ifail] = s19ab(x)
```

3 Description

s19ab evaluates an approximation to the Kelvin function $\text{bei } x$.

Note: $\text{bei}(-x) = \text{bei } x$, so the approximation need only consider $x \geq 0.0$.

The function is based on several Chebyshev expansions:

For $0 \leq x \leq 5$,

$$\text{bei } x = \frac{x^2}{4} \sum_{r=0}^l a_r T_r(t), \quad \text{with } t = 2\left(\frac{x}{5}\right)^4 - 1;$$

For $x > 5$,

$$\begin{aligned} \text{bei } x = & \frac{e^{x/\sqrt{2}}}{\sqrt{2\pi x}} \left[\left(1 + \frac{1}{x}a(t)\right) \sin \alpha - \frac{1}{x}b(t) \cos \alpha \right] \\ & + \frac{e^{x/\sqrt{2}}}{\sqrt{2\pi x}} \left[\left(1 + \frac{1}{x}c(t)\right) \cos \beta - \frac{1}{x}d(t) \sin \beta \right] \end{aligned}$$

where $\alpha = \frac{x}{\sqrt{2}} - \frac{\pi}{8}$, $\beta = \frac{x}{\sqrt{2}} + \frac{\pi}{8}$,

and $a(t)$, $b(t)$, $c(t)$, and $d(t)$ are expansions in the variable $t = \frac{10}{x} - 1$.

When x is sufficiently close to zero, the result is computed as $\text{bei } x = \frac{x^2}{4}$. If this result would underflow, the result returned is $\text{bei } x = 0.0$.

For large x , there is a danger of the result being totally inaccurate, as the error amplification factor grows in an essentially exponential manner; therefore the function must fail.

5 Parameters

5.1 Compulsory Input Parameters

1: **x – double scalar**

The argument x of the function.

5.2 Optional Input Parameters

None.

5.3 Input Parameters Omitted from the MATLAB Interface

None.

5.4 Output Parameters

1: **result** – double scalar

The result of the function.

2: **ifail** – int32 scalar

0 unless the function detects an error (see Section 6).

6 Error Indicators and Warnings

Errors or warnings detected by the function:

ifail = 1

On entry, $\text{ABS}(x)$ is too large for an accurate result to be returned. On soft failure, the function returns zero.

7 Accuracy

Since the function is oscillatory, the absolute error rather than the relative error is important. Let E be the absolute error in the function, and δ be the relative error in the argument. If δ is somewhat larger than the *machine precision*, then we have:

$$E \simeq \left| \frac{x}{\sqrt{2}} (-\text{ber}_1 x + \text{bei}_1 x) \right| \delta$$

(provided E is within machine bounds).

For small x the error amplification is insignificant and thus the absolute error is effectively bounded by the *machine precision*.

For medium and large x , the error behaviour is oscillatory and its amplitude grows like $\sqrt{\frac{x}{2\pi}} e^{x/\sqrt{2}}$.

Therefore it is impossible to calculate the functions with any accuracy when $\sqrt{x} e^{x/\sqrt{2}} > \frac{\sqrt{2\pi}}{\delta}$. Note that this value of x is much smaller than the minimum value of x for which the function overflows.

8 Further Comments

None.

9 Example

```
x = 0.1;
[result, ifail] = s19ab(x)

result =
    0.0025
ifail =
    0
```
